List of Figures

Every figure is drawn from the code it pictures, by one of two kits (`docs/book/figures.py`; `docs/book/schematics.py` for the wiring schematics, block diagrams, flowcharts, timing diagrams, state machines, the receipts charted from their own tables and the grids), and printed where the text first needs it; the same drawings stand beside the text on GitHub, in `docs/book/figures/`. A chart of a receipt is read by the reading key: it pictures the table and adds nothing to it.

Figure 1. Block diagram: the verdict's paired trial around a slow knob, read GAIN, STEADY or LOSS 4

Figure 2. State machine: the governor's modes 5

Figure 3. One pedal, no brake: the modes and the two switches 7

Figure 4. The compass band, its cushions, and the smoothing of the force 9

Figure 5. The engine's six states, their couplings and the control law 48

Figure 6. The double well of the alignment and the cubic potential of the stress 49

Figure 7. Block diagram: from the observations through the engine to the authority 50

Figure 8. Modelled trace: the engine's six states answering a pressure pulse 52

Figure 9. One decision of the governor, from the senses to the audit 55

Figure 10. Block diagram: the compass law as a closed loop on one muscle 135

Figure 11. Curve: the damping gain the law sets from a muscle's response time 138

Figure 12. Grid: the force over the band position and its rate of change 139

The Problem and the Answer

The bottom line, first: is Omni-Compass a benefit? The founder's order of 24 October 2026: the first thing anyone sees says whether Omni-Compass is a benefit, for each way to run it, against native alone, in one light and one number. The light is the whole verdict: green and round, **GAINING**, Omni-Compass ahead of native; yellow, a yield diamond, **STEADY**, STEADY (a change under 0.5%); red, a stop-sign octagon, **REDLINING**, behind native, a LOSS; dark, **AWAITING**, no run yet. A slower service or a failed request turns the light red whatever the work.

The number is how much more work was done for the same demand, the mean of our three runs (one real test on GitHub's own machines, class L; `results/orchestrator/V21_THREE_ARMS_ABC.md`, engine omni-v21, commit `9d2bea96a878`; section 60.3):

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Way to run it	Light	Work against native	Everything else the record reads
Native alone (Kubernetes' published autoscaling rule on the muscles, written by us as the yardstick)	yellow, STEADY	0%: the baseline	—
Omni-Compass on native	green, GAINING	**GAIN 8.5%** in all three of our runs (raw A +10.3%, B +8.2%, C +7.0%)	the 95th percentile **GAIN 13.0%** in all three of our runs (raw A −12.6%, B −14.2%, C −12.0%); machines **GAIN 3.2%** by the mean of our three runs, beyond the noise in 1 of 3 (raw A −2.0%, B −2.8%, C −4.8%); serving units **power given 4.0%** by the mean of our three runs, beyond the noise in 1 of 3 (raw A +3.3%, B +5.0%, C +3.7%)
Omni-Compass direct (Omni-Compass alone on the muscles, no Kubernetes)	green, GAINING	**GAIN 6.0%** by the mean of our three runs, beyond the noise in 2 of 3 (raw A +10.0%, B +5.3%, C +2.8%)	the 95th percentile **GAIN 9.9%** by the mean of our three runs, beyond the noise in 1 of 3 (raw A −14.3%, B −7.6%, C −7.6%); machines **GAIN 2.8%** by the mean of our three runs, beyond the noise in 0 of 3 (raw A −3.0%, B −2.8%, C −2.6%); serving units **power given 3.5%** by the mean of our three runs, beyond the noise in 1 of 3 (raw A +4.6%, B +4.0%, C +1.8%)

The whole workload, composed layer by layer (a model of measurements, class S of class L and P; section 60.6): **GAIN 43.4%** over work, speed and machines, the cloud's layer entering as exactly 1 (it holds), every interval carried (+27.7% to +60.9% with the gauges correlated; `results/WHOLE_SYSTEM.md`). It is the composition's index, not a price: a bill is the sum of the costs inside a declared boundary, and neither route's bill is resolved yet (section 76.8). Every real test together, the Omni index of Omni-Compass on native reads **GAIN 20.0%**, work, speed and machines read together, its categories from real messaging **GAIN 221.1%** to the database's buffer pool **power given 12.5%** (section 60.11).

All patents, copyrights and trademarks filed in the USA.

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

What the whole industry faces. Every computing system in service, from one server to a cloud region, from a GPU to a building's chillers, a grid feeder or a robot cell, is run by a stack of native controllers: the Kubernetes autoscalers and scheduler, the cloud's node pools, the GPU's power and clock firmware, the database's cache and connection pools, the building's cooling loops, the battery's management system, the servo's loop. Each was designed and tuned alone, against its own setpoint, with margins sized for the worst case it might meet. Three costs follow, on every stack:

1. **Capacity held idle.** Worst-case margins stay in place through the common case. Machines, power caps, caches and cooling run far inside their limits, and the room between the operating point and the limit is paid for and seldom used.
2. **Late reaction.** Reactive loops act on averaged, lagging signals and wait out deliberate cooldowns, so queues and response-time tails form before capacity arrives.
3. **Loops at cross purposes.** The loops share power, cooling, connections and memory. One loop's correction is another loop's disturbance, and no loop sees the whole.

Demand for computing, above all for AI and the cloud, is growing faster than the power, cooling and hardware that can be built for it. The usual answer is to add: more machines, more power, more people watching thresholds. Replacing the native controllers is not an answer most operators will take: they are proven, often certified, and the people on call know them.

What Omni-Compass does about it. Omni-Compass is a supervisory governor. It sits on top of those native controllers and never replaces them. It never touches the data: no request, packet, file or byte of the work passes through it. It plugs into each setting a native controller already exposes, through a two-way plug (one wire in, the reading; one wire out, the setting), takes a snapshot of every setting before its first write, and governs the whole stack as one body, the organism: every muscle driven as far as its own limit and never past it, and, on the engine that stands, never below native; where it cannot bring a muscle a GAIN, that muscle stays native. It acts before a line is crossed instead of after, reads back every write, puts every give-back to its own trial, records every decision with its reason, walks every setting home if it stops (the lease) and stops at once on the kill switch. Its first rule is do no harm, judged at the organism: never less work or health than native (`DISCLOSURES.md`, section 3). The one headline is an aim, not a result. The aim: more work, faster, on fewer machines, for the same energy and the same bill, from the hardware and the controllers already in place, every benefit made at the software end; in a cloud and at the chip, Omni-Compass holds. The record reads the work and the speed (the Omni index, `results/OMNI_INDEX.md`); the machines are not yet fewer: the whole organism's composition reads them more, power given (`results/WHOLE_SYSTEM.md`).

What the record shows so far. Every claim is a paired comparison of native and Omni-Compass on top of native, and since 23 October of Omni-Compass direct beside them, on the same machines with the same work, run three separate times (A, B and C) and read GAIN, STEADY or LOSS by what each gauge is for; every row is kept, LOSS included.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

On real machines (class L, live software), the combined Omni index, work, speed and machines read together, stands at **GAIN 20.0%**, and the service reading alone, work and speed, at **GAIN 96.5%**, judged across our three runs by the rule of 24 October (`results/OMNI_INDEX.md`; 26 tests, each read from its own engine's newest three-run table, 26 on omni-v26; none pooled across engines). The rows that read LOSS stand in their tables, no whole category among them, as does the pod start wait on the kind rig (`docs/POD_START_WAIT.md`).

The 1,107 muscles of the catalog are modelled (class S) and are never shown as proof of hardware. The engine is written twice, in Python and in C++, and the Python's 500 seeded runs through the C++ harness are identical to the last bit (`cpp/tools/engine_runs.cpp`; GitHub reruns the 500 on every change to the harness, the engine's C++ or the page, and every verify reruns 50 of them). Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

What is not claimed. No new physics, no new model of computation, and no promise for any system Omni-Compass was not run on. It does not make a system immune to failure, delay or drift: it keeps each muscle inside its own limits and shows, row by row, what it did against native. A result on another system is that system's own, from its own paired runs; where it differs, the first presumption is the wiring (`DISCLOSURES.md`, section 4).

What is protected, and how. Omni-Compass belongs to Dubra Software Inc. / The Omni-Compass LLC. Its source, manuals and records are its copyrighted work; all patents, copyrights and trademarks filed in the USA. The repository is licensed for Evaluation and Simulation use only (`LICENSE`); any commercial use, monetization or production use requires a signed, paid Omni-Compass Enterprise License (`ENTERPRISE_LICENSE.md`). What a licensee acquires is the working whole: the engine, the wiring and the factory card of every muscle, the harness that measures it against native, and the receipts.

The cloud is a wire. A cloud is the wire between the software end (the owner's programs, Kubernetes and the open-source orchestrators, managers and autoscalers that carry the work) and the hardware end (the bare metal: the GPU chips, the Linux racks, the data center, on site or off site). Omni-Compass sits on all three pieces where a system lets it (the software end in either place, the chip only on bare metal); a system itself runs in one of two places, bare metal or the cloud (the founder's order of 1 November). On the wire alone, as every cloud run in this repository is set, it can only park machines the cloud's own autoscaler already made, so a cloud run alone can show at most a small cut in the bill of the wire; the work and speed gained at the software end and the energy and throughput gained at the bare metal are measured where Omni-Compass sits on them, and composed with the wire into one organism and one bill (`DISCLOSURES.md`, section 9; section 60.6, with the company's expected ranges beside the measured readings, an expectation and never a result).

Foreword

I built Omni-Compass to sit on top of what already exists. Kubernetes, the GPU driver, the building controller, the battery inverter, the robot's servo loop: those are muscles, and they are good muscles. What none of them has is one brain that reads all of them at once, holds each of them inside its safe range, and puts every setting back exactly where it found it when it stops. That brain is Omni-Compass.

Every machine already has a controller. Kubernetes has its autoscaler. A graphics card has its firmware. A building has its thermostat loop, a battery has its charge controller, a power grid has its tap changers, and a robot has its servo. Engineers spent decades making these controllers safe, and they are. But each one was built to watch one thing and to protect that one thing. None of them sees the whole body. None of them knows that the cooling loop is holding back the processor, or that the autoscaler is adding machines the database cannot feed. So each one plays it safe in the middle of its range, because playing it safe is its whole job. The headroom between the middle and the edge is paid for every hour and almost never used.

That gap is what I set out to close. Omni-Compass is a **supervisory governor**: one brain over the muscles you already run. It never replaces them and it never competes with them. It reads them, it decides, and it writes one setting at a time through a two-way plug: one wire in, one wire out. Before it writes anything, it takes a snapshot. When it stops, every setting goes back to that snapshot.

Why a compass. A compass always points home. Every muscle has a safe band, and the compass holds the muscle inside that band, with a cushion of 5% at each edge. It works with two forces that pull against each other, one toward more and one toward less, and it moves smoothly, never hammering. A system that is closed, bounded and pulled toward a center cannot run away. That one idea is the root of the whole engine, and the first part of this book explains it.

The rule I will not bend: do no harm. Its real goal is the organism: to strengthen it and keep it healthy, working at the best state its own muscles can carry. Whatever is fed into it, its work, its data, its energy, goes through its muscles and comes out as its output, and Omni-Compass drives it toward the most and best output it can make. Harm is the organism turning out less than its native controllers make it turn out, or made less healthy: a muscle pushed past its own limit, a service over its own line, anything made to fail. Omni-Compass never does either. It can push a muscle only as far as that muscle itself can go; it may use one muscle less, or leave it native, so that another can carry more, whenever the whole organism comes out ahead and every muscle stays healthy (`DISCLOSURES.md`, section 3). The engine that stands keeps the rule in its strictest form, a trigger in the code (`omnicompass/verdict.py`), checked on the muscle itself, step after step: a

All patents, copyrights and trademarks filed in the USA.

step that costs the muscle more for each piece of work is undone, and where it cannot bring a muscle a gain, that muscle stays native.

The max is the default. Most tuning tools try to shave a little off. Omni-Compass rides the edge instead: every muscle runs up to its own limit, read live from the system, never past it and never below what native gives. The energy it takes to do more work is **power given**, shown beside the work, the speed and the wear it bought. It is never called a loss. Anyone can turn the dial down from the max. Nobody has to.

One pedal. I wanted it to drive like an electric car. Push the pedal for more, lift off for less. Lift off all the way and the settings drift back toward native. Reset hands everything back. If the governor ever crashes, its lease runs out and the plug walks every setting home, step by step. The kill switch is separate and instant, and it exists for security, not for daily driving.

How I want it judged. Every benchmark in this book sets native beside Omni-Compass on top of native, and, where native's own controller can be switched off, Omni-Compass direct beside them ("there's native, there's Omni and native, and then there's Omni by itself", 23 October); there is no other arm and no other name. Every result was run three separate times, under rules written down before the first run, and every row is shown, losses included. Each reading is one word, **GAIN**, **STEADY** or **LOSS**, decided by what the gauge is for. A result from our own model is labeled as a model; a result from live software is labeled as live software; only a meter speaks for hardware. Where we lost, the book says so, and we went to find out why. Nobody outside Dubra Software Inc. / The Omni-Compass LLC has reviewed or approved these results, and every table says that too.

What this book holds. This manual is the whole of it: what the governor is, the mathematics it runs on, how its nervous system reads and writes, how it is wired to each kind of machine, how to turn it on one level at a time, how to switch it off, and how to prove on your own system what it does. Keep it with the code. When the code changes, this manual changes in the same commit.

On this edition. This edition is written for the referee and the underwriter as much as for the engineer. Every result in it was run three separate times on a frozen, fingerprinted engine, under rules written before the first run, and is reported with every loss beside every gain. Where a number is from a model it says so; where a test could not see an effect it says so; where something has not been shown it says so, in its own section. Nothing in this manual asks to be believed on our word: every table names the runs it was made from, every run's raw files are in the repository, and every table can be rebuilt from them by the tool it names.

Where to begin. Read the front matter first. It tells you what you are looking at before it asks you to touch anything. Then wire it one level at a time, watch it before you let it write, and judge it by your own receipts.

Preface

This is the Owner's Manual, the master: everything about Omni-Compass in one book, for whoever owns or licenses it and so must know the whole mechanism. I wrote it so that the owner understands what they hold: not only which wire goes where, but why the governor behaves the way it does, where its law comes from, how it is built, and how to prove on their own system what it does for them. The Operator's Manual is the shorter book for the people who run it.

The book is in eight parts, and it can be read in two ways.

You are	Read
CEO, board member, investor	the Problem and the Answer, the Foreword, the Prelude, the Introduction, the Executive Summary, Part One, the Results to Date, and Part Eight
CTO, architect, head of platform	Parts One to Four, then the eight wiring levels in Part Five, then Part Seven
The engineer wiring it	everything, in order. Do not skip the wire check or the watch level
Data-center, facility or energy operator	the Quick Reference card, Part One's chapter on the reflex, Part Five (levels five to seven, the processor and the data center under the servers), Part Six
Site reliability engineer, on call	the Quick Reference card, Part Six (the switches and the log), the troubleshooting appendix
Auditor, diligence team	Part Two (the mathematics), Part Seven (the proof), Appendices C, F and H
Procurement and counsel	the Disclosures, the license in the back matter, Part Eight

Part One, the philosophy and the theory, sets out the closed circle: a system that is closed, bounded and pulled toward a center cannot run away, and everything it does is a return. **Part Two, the mathematics,** gives the eight equations and the control law that make the circle exact, with the theorem, the declaration and the audits that hold them fixed. **Part Three, the physics,** brings the law into the machine: the compass, push and pull, the band and its cushions, the physics of a processor, and the two-way nervous system. **Part Four, the body,** lays out the muscles, the spine, the four realms and the seven organisms. **Part Five, the harness and**

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

the wiring, is the universal plug and the step-by-step work of wiring Omni-Compass onto a stack. **Part Six, operating it,** is the OFF switch, the rules and the log. **Part Seven, proving it,** is every rule written before a run and every result after it. **Part Eight** is value, the license, the seal and the history.

Conventions. `Code` is a command, file or switch exactly as typed. "Native" means a system as it runs today, without Omni-Compass. "Muscle" means any machine, service or controller Omni-Compass can read and set. "Knob" or "lever" is one setting on a muscle. "The band" is a knob's or a service reading's safe range. A step that writes to a system is marked **WRITES**. Every result carries its evidence class: T for a theorem, V for verification of the code, S for our own models (modelled), L for live software, P for a physical meter.

Some chapters gather documents that were written as the work went on, each at the moment its result came in. They are kept as they were written, because the record of how a result was reached is part of the proof. Where two chapters give different figures for the same thing, the later run and the State of Play govern.

The standards every page of this manual keeps. A referee or an underwriter reading this manual should expect, and will find, the following discipline throughout, because it is the discipline the repository enforces on itself:

1. **Native beside it, always.** Every benchmark is read against native, on the same machines, with the same work at the same moments: omni (Omni-Compass on native) against native, and, where it is run, Omni-Compass direct against native and against omni. Omni-Compass on native is never compared as a competitor to the controller it sits on; the direct arm switches that controller off to show what Omni-Compass does as the only controller, and is never read in place of the arm on native.
2. **Preregistered, then run.** The arms, the knob, its cover, the gauges, their directions and the readings are written down and committed before the first counted run (`docs/*_PREREGISTRATION.md`). Rules are frozen on one tuning case that is shown and never counted, then applied unchanged to untouched cases. Any amendment made after a result has been seen is written into the preregistration with its time and reason, and the table that carries the result says so.
3. **Three separate runs, one rule.** Every result is run three times as separate GitHub runs (A, B and C) on the same frozen engine and profile, and every judged row reads by one rule: the change is the mean of the three runs' changes in percent of native; a mean under 0.5% reads STEADY, under the floor (STEADY, the same where nothing moved); from 0.5% up the word comes from what the gauge is for, GAIN, LOSS or power given, **in all three of our runs** where every run moved the same way with its 95% interval clear of zero, otherwise **by the mean of our three runs** with the count of runs beyond the noise; runs that moved 0.5% or more in opposite directions read **the runs disagree**. Nobody outside Dubra Software Inc. / The Omni-Compass LLC has reviewed or approved these results, and every three-run table says so.
4. **Every row, losses included.** A row that went against Omni-Compass is in the table beside the rows that went for it. When Omni-Compass loses, the first suspect is our own wiring, native setup or scoring; when that is fixed, the test is run again and the loss stays in the record. A benchmark may be left unpublished; it is never published with rows cut.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

5. **Nothing read across engines.** The engine is frozen and fingerprinted (`OMNI_V1.json`, `OMNI_V2.json`, `OMNI_V3.json`, `OMNI_V5.json`, `OMNI_V6.json`, `OMNI_V7.json`). Any change to a rule, gain, guard, preset or muscle makes the next version, and every result is run again on it. Every table made by rule checks the engine of each run it reads and refuses to mix them.
6. **The raw files live with the code.** Every finished run's files are copied into `run-<id>/` on the repository's branch `raw` with one SHA-256 manifest per repetition (opened by `scripts/raw_archive.sh`, the branch sits at `results/live/raw/`), and every table names the runs and the commit it was made from. Anyone with the repository can recompute every table from the files it names.
7. **Do no harm.** The organism is never left turning out less than native, nor less healthy, and every muscle works only as far as its own limit (`DISCLOSURES.md`, section 3). On the engine that stands, Omni-Compass moves a knob only where a paired trial on the muscle itself shows the muscle never behind for it (the verdict, `omnicompass/verdict.py`, with its 2% allowance). Where it cannot improve a knob, that knob stays native, and the result says "nothing for Omni to move".

Prelude: A Night on the Cluster

This is a story, not a result. It follows one night on one cluster to show, in plain order, what each part of this book does. The shop, the times and the settings are made up for the story. The measured results are in the chapters on proof, each with its evidence class.

9:00 p.m. The shop is quiet. An online store runs on Kubernetes. Its native controllers are the ones almost everybody uses. The Horizontal Pod Autoscaler watches the average processor load and adds copies of the web service (pods) when that load passes its target. The cluster autoscaler adds machines when the pods no longer fit. A careful engineer picked their settings months ago, for the worst day she could imagine, and she picked them well. Tonight the cluster runs on its floor of two machines, and every customer gets an answer in a blink.

A week earlier, Omni-Compass went on in watch mode. For seven days it read every gauge and wrote nothing. It learned how fast each pod starts, how the response time moves when the load moves, and where each setting's safe band lies. Then the team ran the wire check: every reading came from the place it claimed, every lever moved the thing it claimed, and every write was read back. Only then did they turn it to govern. Every setting it would touch was saved in a snapshot first.

9:40 p.m. The sale starts. In two minutes the requests double. The native autoscaler does exactly what it was built to do, but it is built to wait: it needs the average load to climb, then it needs a decision, then each new pod needs time to start. While it waits, customers wait. With Omni-Compass on top, the compass sees the response time slide toward the edge of its band and into the cushion. It pushes. It raises the autoscaler's floor of pods, a

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

setting the autoscaler already respects, so new pods start before the average catches up. It does not fight the autoscaler and it does not go around it. It moves one setting, through the plug, and reads it back.

10:15 p.m. The database starts to strain. More web pods mean more connections to the database, and the database has a limit of its own. A controller that watches only the web service would keep adding pods and deepen the jam. Omni-Compass sees the whole body. One body, one brain: before it takes the next step for the web service, it checks what that step would do to every other part. The step that would push the database past its own cushion is refused. Nothing is pushed into a loss to buy a gain somewhere else. The web service holds where the database can still keep up, and the queue drains instead of growing.

11:30 p.m. The rush fades. The pedal lifts. Omni-Compass does not drop everything at once, because a sudden drop is how systems stumble. It eases each setting back toward native along a smooth curve. The extra machines go away as the work goes away. The energy the cluster used during the rush shows up in the report as power given, beside the work it bought and the minutes customers did not spend waiting.

1:00 a.m. Idle. The pedal is lifted all the way. The cluster sits on its floor of two machines again, exactly where the engineer left it. Omni-Compass keeps reading every second. Staying native is its live decision, made again each second, not a verdict from some earlier run.

3:12 a.m. Something breaks. An upgrade restarts the machine that runs the governor, and Omni-Compass stops in the middle of its work. Nobody is awake. Nothing bad happens. The governor's lease runs out, and the plug walks every setting back to its snapshot, step by step. The native controllers keep running as they always have, because they never stopped. When the governor comes back, it starts from what it reads, not from what it remembers.

7:00 a.m. The morning report. On a live system, the proof does not come from a feeling that the night went well. It comes from paired runs: the same work, run once on native and once with Omni-Compass on top, and compared gauge by gauge. Every gauge gets one word. Time waited that fell reads **GAIN**. Work done that rose reads **GAIN**. A change under half of one percent reads **STEADY**, and the report says so plainly; a change of 0.5% or more shows its word. A gauge that moved the wrong way reads **LOSS**, and it stays in the report until its cause is found and fixed. The energy spent on extra work reads **power given**, never a loss.

What the night shows. Every part of that night is a chapter of this book:

- the watch mode and the wire check are in the chapters on wiring, level by level;
- the band, the cushions and the two forces are in the chapters on the compass;
- one body, one brain is the reflex rule, in the first part;
- the snapshot, the lease and the kill switch are in the chapters on operating it;
- the paired runs and the three words are in the chapters on proof.

Read the rest of the front matter before you touch a wire. It tells you what you are looking at and how to read what it tells you.

Introduction: The Idea and the Promise

The problem. Stated in brief at the front of this book ("The Problem and the Answer"); here in engineering terms. Production systems are governed by many local feedback loops: horizontal autoscalers, firmware power and clock governors, building-management loops, battery-management systems, connection pools, servo controllers. Each loop is tuned in isolation, against its own setpoint, with margins sized for a worst-case disturbance. Three costs follow, and every operator pays them:

- **Reaction latency.** Reactive loops act on lagging, averaged signals. A Kubernetes Horizontal Pod Autoscaler recomputes its desired replicas from averaged utilization on a sync period (15 seconds by default) and damps its decisions with stabilization windows; new pods then need time to schedule and start. Queues form before capacity arrives.
- **Static over-provisioning.** Worst-case margins persist through the far more common nominal regime. The operating point sits well inside the safe region, and the headroom between it and the constraint boundary is paid for and rarely used.
- **Uncoordinated coupling.** Loops share resources: power, cooling, connections, memory, network. One loop's correction is another loop's disturbance. More web replicas saturate the database's connections; more cooling pushes a power feed toward its limit.

Operators close these gaps by hand, with fixed settings and runbooks. That is safe, and it leaves the region between the nominal operating point and the safe boundary unused nearly all of the time.

The idea. Close one supervisory loop around the native loops. Omni-Compass treats each setting a native controller already exposes (a replica floor, a power cap, a clock ceiling, a temperature setpoint, a pool size) as an actuator, each native telemetry stream as a measurement, and governs the whole body from above. Every decision period it runs five steps:

1. **Sense.** It reads each muscle's own gauges through the plug: utilization, response-time percentiles, queue depth, temperature, power, state of charge.
2. **Normalize.** It places each reading in its band as a compass position, from 0 (calm) to 1 (the line), with a 5% cushion at each edge.
3. **Decide.** The compass law turns that position into one bounded increment per actuator: two antagonist forces, push and pull, each with its own gain, combined through a smooth saturating response (tanh), so the command is continuous, bounded and never chatters. The increment is clipped to the actuator's cover, the hard range nothing can leave.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

4. **Actuate.** It writes the increment through the plug, idempotently, and reads the value back to confirm the write landed.
5. **Verify.** The verdict compares the muscle with and without the step in a paired trial on the muscle itself, judged on the muscle's own cost per unit of work; the body guard checks every coupled muscle against its own cushion. A step that fails either test is reverted.

What Omni-Compass is not.

- It is **not a replacement** for your controllers. Native keeps running underneath, always. Omni-Compass only moves settings that native already exposes and respects.
- It is **not a black box**. Every decision is written to a log, with the reading that caused it and the setting it changed.
- It is **not a one-time tuning script**. It decides again every second, and staying native is one of its decisions.
- It is **not a cost-cutter first**. It gives power where the power buys work or speed, and it shows that power beside what it bought.

The promise, in three parts.

1. **Do no harm.** The organism is never left turning out less than native, nor less healthy, and no muscle is pushed past its own limit. On the engine that stands, a step stays only where the muscle takes no LOSS from it, measured on the muscle itself; where Omni-Compass cannot bring a gain, the muscle stays native.
2. **Everything comes back.** Every setting is saved before the first write and restored when Omni-Compass stops. If the governor crashes, its lease runs out and the settings walk home on their own. A separate kill switch stops everything at once.
3. **Every claim is checked.** Each benchmark compares two arms, native and Omni-Compass on top of native, on the same machines with the same work. Each runs three separate times. Each reading is one word, GAIN, STEADY or LOSS, decided by what the gauge is for. Each result carries its evidence class: **P** for a physical meter, **L** for live software, **S** for our own models. A model is never shown as proof of hardware.

What it governs. The catalog names 1,107 muscles in 70 families, the settings that operators everywhere already turn by hand: machine pools and replicas, power caps and clock limits, cache sizes and connection pools, cooling setpoints and battery reserves, robot speeds and drone-swarm settings, and many more. They are grouped into four realms (compute, AI and cloud; physics, robotics and autonomy; energy, facility and industry; distribution and specialized systems) and run together as seven organisms, from the spine alone (the muscles every stack runs on) and one realm alone up to the whole tower at once. The muscles in the catalog are modelled (class S). The real controllers it has been run on top of, such as Kubernetes and the databases, are live software (class L). The chapter that follows the key, "What You Are Looking At," shows which is which. Appendix G lists every one of the 1,107 muscles: what it is, what Omni-Compass reads from it, what it moves, the organisms it belongs to, and its own card, the factory setting it runs on; and for each of the 70 families,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

how to wire it on any stack: the native controller that owns it, the wire out (what is read, and where), the wire in (what is written, and where), the restore, and whether that wire has run live in this repository or only on a model (`docs/wiring_recipes.csv`).

What you need before you wire it.

- **A license for any use beyond evaluation.** Production use requires a signed, paid Omni-Compass Enterprise License.
- **Read access first.** Omni-Compass starts in watch mode: it reads and computes, and writes nothing.
- **The wire check.** Every reading must come from where it claims, every lever must move what it claims, and every write must read back. Nothing writes until the check passes.
- **Your own service line.** The response time or other limit your service must meet comes from your own service objectives, not from ours.
- **Paired runs on your own system.** The only number that applies to your system is the one your own paired runs produce, on your own receipt.

How to read what follows. Next comes the key to the three words, then "What You Are Looking At," which shows what a hooked-up system looks like and how to read its report. The Quick Reference card is the page to keep beside the system. The Executive Summary gives the results in brief, and the Disclosures make every declaration once. After that the book turns to the theory, the mathematics, the physics, the body, and only then to the wiring, the operation and the proof. Read in that order, nothing in the wiring chapters should surprise you.

The key: GAIN, STEADY and LOSS

Every judged reading in Omni-Compass is one of three words: **GAIN**, **STEADY** or **LOSS**. Better, same and worse are not used anywhere. The word is decided by what the gauge is for, never by the plus or minus sign of its number: who sets the aim differs from one system to the next, and each gauge's aim is written in its preregistration before the runs.

Word	What each letter stands for	Its sense in underwriting	What it means in a table
GAIN	**G** Growth (asset appreciation); **A** Advantage (risk reduction); **I** Improvement (margin expansion); **N** Net-positive (profitable outcome)	surplus and positive variance	the gauge moved toward its declared aim against native: more work done, a shorter wait, fewer misses or failures, or a resource cut

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Word	What each letter stands for	Its sense in underwriting	What it means in a table
STEADY	**S** Stable (zero variance); **T** True to baseline (expected norm); **E** Equilibrium (balanced risk); **A** At par (no net change); **D** Drift-free (within the 0.5% floor); **Y** Yield held (nothing lost)	the par baseline: equilibrium	native and Omni-Compass within 0.5% of each other: the mean of the three runs' changes under the 0.5% floor, or no change at all; a knob native already runs at the top of its range is STEADY, at its limit on native
LOSS	**L** Leakage (capital drain); **O** Off-track (adverse selection); **S** Setback (claim liability); **S** Subpar (negative variance)	actuarial deficit and exposure	the gauge moved away from its declared aim: less work done, a longer wait, more misses or failures

How the sign of a number becomes a word:

- **Time waited, missed or failed** (a response time, time over the line, failed requests): a fall is GAIN, a rise is LOSS.
- **Work done** (work inside the line, throughput, a hit rate): a rise is GAIN, a fall is LOSS.
- **A resource spent or held** (energy, the power drawn and its peaks and swings, machines, memory, processor time, a bill, wear on a part): a fall is a **cut**, and a cut is GAIN. A rise is **power given**: what Omni put in to buy the work and the speed shown beside it. Power given is always shown and never hidden, and it is never called a loss (the founder's order of 12 October 2026: the max rides every muscle's edge; it never shaves). A peak is power held, so a peak that rose is power given, in a data centre and in a building alike (17 October).
- **Work bought with each unit of a resource** (work per energy): a rise is a cut in what each unit of work took, a GAIN; a fall is power given, because it falls when more power is given for the same work.
- So a minus can read GAIN (a response time cut 65%, a bill cut 30%) and a plus can read LOSS (failed requests up).
- **The floor, and every change above it** (the founder's orders of 20 and 24 October 2026): a change of half of one percent (0.5%) or more either way is a change, and reads **GAIN** or **LOSS** (or **power given**) by what the gauge is for; STEADY is kept for a change under 0.5%. The change is the mean of the three runs' changes, each in percent of native. Where every run moved the same way with its 95% interval clear of zero, the word reads **in all three of our runs**; otherwise it reads **by the mean of our three runs** and says in how many of the three runs it stood beyond the noise, so a reader sees how firmly it stands. Where runs moved 0.5% or more in opposite directions, the reading is **the runs disagree**. A mean under 0.5% reads **STEADY, under the floor**, with its size.
- **Two numbers, never mixed** (the referee's work order of 25 October): every row shows native's value and Omni-Compass's, the **raw change** (Omni-Compass − native) / native with its true sign, + for a rise and −

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

for a fall whatever the gauge is for, labelled raw, and apart from it the word with its size and no sign. A bill cut 3% reads raw −3.0%, GAIN 3.0%; failed requests up 2% read raw +2.0%, LOSS 2.0%; a pod start wait from 0.22 s to 0.83 s reads raw +275.0%, LOSS 275.0%; a change under the 0.5% floor reads STEADY 0.3%. No raw sign is ever turned to match a word.

Some preregistrations name their outcome with a label written before the runs (for example SUPERIOR WITHIN GUARDRAILS in the card protocol). The label stays as it was frozen, and every table shows it with its word first: TOWARD ITS AIMS reads GAIN; BOTH WAYS reads GAIN AND LOSS; AWAY FROM ITS AIMS reads LOSS; SAME AS NATIVE reads STEADY (the same as native); AT ITS LIMIT ON NATIVE reads STEADY (at its limit on native); SUPERIOR WITHIN GUARDRAILS reads GAIN (within the guardrails); ENERGY IMPROVEMENT WITH SERVICE TRADEOFF reads GAIN AND LOSS (energy cut, service traded for it); SERVICE IMPROVEMENT WITH ENERGY TRADEOFF reads GAIN, power given (service GAIN, energy given for it); NONINFERIOR / INCONCLUSIVE reads STEADY (inside the noise, within the guardrails); NOT ESTABLISHED reads STEADY (not established: inside the noise, a guardrail crossed on the mean). A run that breaks its own validity checks reads INVALID and carries no word.

Every reading is one of these. **GAIN, LOSS or power given in all three of our runs**: A, B and C moved the same way, every 95% interval clear of zero. **GAIN, LOSS or power given by the mean of our three runs**: the runs' mean moved 0.5% or more, with the count of runs that stood beyond the noise beside it. **STEADY, under the floor**: the mean moved less than 0.5%. **STEADY, the same**: no change at all. **The runs disagree**: runs moved 0.5% or more in opposite directions, so the test is unstable there and is looked into. **Shown, not judged**: a gauge declared in advance as shown only, such as the knob's own setting.

Why these three words: they are the words of underwriting and actuarial work, where every outcome is graded as surplus, par or deficit, and each letter spells out the same rule. Omni-Compass is there to add (GAIN), never to take (LOSS), and to hand a muscle back to its own native setting where it cannot add (STEADY). Its first rule is do no harm, in the founder's meaning of 19 October 2026: the organism Omni-Compass governs is never left turning out less than its native controllers make it turn out, nor less healthy, and every muscle works only as far as its own limit (`DISCLOSURES.md`, section 3). So **LOSS should never appear**: where it does, the row stays in the table, its cause is found and fixed (our own wiring first, then native's setup, then the scoring) and the test is run again.

Disclosure and disclaimer: GAIN, STEADY and LOSS, and the letters behind them, are Dubra Software Inc. / The Omni-Compass LLC's own convention for reading its own results. The underwriting senses explain the words; they are not an actuarial, financial or insurance opinion, and no outside body defined, reviewed or approved them. A reading states what our own runs measured against native under the declared aims, not a promise about any other system; every number stands beside its word, so a reader can judge it by any other convention. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

All patents, copyrights and trademarks filed in the USA.

What You Are Looking At

What Omni-Compass is. Omni-Compass is a supervisory governor. It is never a controller of its own and never a replacement for one: it sits on top of the controllers a system already runs (the Kubernetes autoscaler, a database's connection pool, a GPU's firmware, a building's battery controller, a power grid's tap changer, a robot's servo) and moves only the settings those controllers already expose to an operator, through one wire in (what it reads) and one wire out (what it writes). Everything the native controller does, it still does. Pull the plug and every setting walks back to where the operator left it (the lease); the kill switch returns them at once.

What "native" means. Native is the same stack, the same muscles, the same machines and the same work, run the way everybody runs it today: the shipped controllers at their shipped or operator settings. Every benchmark sets omni beside native, where omni (Omni-Compass on native) is that same native stack with Omni-Compass on top; since the founder's order of 23 October a third arm runs beside them wherever a muscle's native is a controller that can be switched off, **Omni-Compass direct**, the same stack with that controller off and Omni-Compass the only controller moving the knob. The three are always shown together, each pair read on its own (section 1.1). Nothing else differs between the arms, so whatever differs in the result is what Omni-Compass did.

What a muscle and an organism are. A muscle is one setting a native controller exposes (a pool's size, a power cap, a clock ceiling, a replica count, a battery's charge rate) together with the gauges that show what it does. Most companies build deep control for one field, and a fleet manager such as Meta's Twine schedules one kind of work (containers) over a very large fleet. Omni-Compass's proposition is different in kind: cross-sector supervision, one supervisor over the shared functional needs of otherwise separate realms. An organism is a stack of muscles from many sectors governed as one body: the four realms (Compute / AI / Cloud; Physics / Robotics / Autonomous; Energy / Facility / Industrial; Distribution / Specialized), the four stacked together, and the whole tower of 1,107 distinct muscles in 70 families. The benchmark of an organism tests what happens when those muscles share one governor and interact.

What has been measured, and how. The breadth of the map and the breadth of the evidence are stated separately:

- **1,107 muscles are catalogued** (`realms/catalog_v5.csv`). Each has a plant model, our own model of that kind of system: evidence class **S** until the muscle is wired to real software or hardware and measured.
- **26 knobs are measured on real, unmodified software** (class **L**): real Kubernetes (9), PostgreSQL behind PgBouncer (3), MySQL (4), MongoDB (4), Apache Kafka (3) and Redis (3), each A, B and C.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **39 knobs are measured inside independent, published simulators** (class **S**, but not our own models): power grids (pandapower with SimBench), buildings and batteries (CityLearn), robot arms (MuJoCo Menagerie), drone swarms (gym-pybullet-drones).
- **Organisms with a real cluster inside**: the modelled organism (S) drives a real Kubernetes cluster (L). "100 copies" means a hundred copies of the modelled organism around one real cluster, not a hundred physical clusters; the number of real machines is always stated beside it.
- **A physical meter** (class **P**) speaks for hardware energy; the GPU's own meter and the processor's RAPL counters are the meters used. Modelled energy is never presented as metered.

What you see when it is hooked up. Every result arrives as a receipt with the same shape: the two arms side by side, every gauge of the system (the work done, the response times, the misses and failures, the machines and energy spent), the paired change with its 95% interval, and one word per gauge, GAIN, STEADY or LOSS (the key, above). A three-run table repeats the test three times, A, B and C, on the same frozen engine and profile, and reads each row by one rule: the change is the mean of the three runs' changes in percent of native; a mean under 0.5% reads STEADY, under the floor (STEADY, the same where nothing moved); from 0.5% up the word comes from what the gauge is for, GAIN, LOSS or power given, **in all three of our runs** where every run moved the same way with its 95% interval clear of zero, otherwise **by the mean of our three runs** with the count of runs beyond the noise; runs that moved 0.5% or more in opposite directions read **the runs disagree** (Chapter 59). Over a benchmark sit three summaries: the Omni index (one number for all real tests together), the benefit sheet (one number and one word per benchmark) and the wiring page (for each knob: write, watch, or the operator's choice).

How to read a report, in order.

1. **The engine and the evidence class.** The header names the engine fingerprint (`python3 tools/omni_version.py`) and the class (P, L or S). A result is never read across engines, and S is never read as proof about real equipment.
2. **The work and the service rows first**: work done, response times, time over the line, failed requests. These say what the system delivered. A GAIN here is the point of the governor; a LOSS here is the first thing to look for.
3. **Then the resource rows**: machines, energy, memory, connections. A cut is a GAIN. A rise is **power given**: what Omni-Compass put in to buy the work and speed above it. Read the two together: power given that bought nothing is the cost to fix.
4. **Then the floor and the noise.** STEADY, a mean change under 0.5% (under the floor) or none at all, is a result, not a failure. A change of 0.5% or more is a change and shows its word, with the count of runs beyond the noise beside it whenever not all three are. The runs disagree means runs that moved 0.5% or more pointed different ways: the test is unstable there and is looked into.
5. **Then the clock and the machine.** Where the test machine itself is the limit (its processor saturated, native alone failing a large share of requests, a run behind its window's clock), the report says so; a test

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

machine's limit is never reported as the governor's result, and the test is rebuilt so the machine no longer decides it.

6. **Every row is shown**, LOSS included. Nothing is cut from a table because it went against Omni-Compass.

How the brain tells GAIN from LOSS. The governor does not read a plus or a minus sign as good or bad. Before it moves anything, every gauge it reads is declared with its aim, and the aim decides the word: for time waited, missed or failed (a response time, time over the line, failed requests) a fall is GAIN; for work done (work inside the line, throughput, missions flown) a rise is GAIN; for a resource spent or held (energy, machines, memory, a bill, wear) a fall is a cut, and a cut is GAIN, while a rise is power given, kept only when it buys work or speed shown beside it. Less energy for the same work is GAIN; more speed for the same machines is GAIN; more work for the same energy is GAIN. In the engine this is done in two places. The verdict (`omnicompass/verdict.py`) lets a muscle's setting move only between native and the deepest step a paired trial on that muscle has shown costs its own work nothing (each piece of work no slower, within the measurement's resolution); a step that costs more is undone at once and not tried again for a while, and where no step passes the muscle stays native, which is STEADY. Inside an organism, the body's guard (the reflex rule, `docs/FORMAL_V5.md`) then refuses any step that pushes another part of the body past its cushion, so no GAIN in one muscle is bought with a LOSS in another.

Wiring it: who, what, when, where, why and how. Read this before the wiring chapters; a governor wired without it may run and still not be the mechanism.

- **Why.** To get more work, faster, with fewer misses, from the machines and the energy already paid for, by letting one brain move the settings native controllers already expose, in the direction each gauge's aim asks, and only while no other gauge pays for it. If nothing can be gained, the purpose is met by leaving native alone.
- **What.** Two things per muscle and nothing else: one wire in (the gauges that show the muscle's state and its work, read live from the system, never typed into code) and one wire out (the one setting native already exposes to an operator, with its hard range read from the system). The brain, the compass, the verdict and the lease are in the engine; the wiring never re-implements them.
- **Where.** On top of the native controller, never in place of it: on the autoscaler's target and ceiling, not on the pods; on the pool's size, not on the queries; on the card's power limit, not on its firmware. Every muscle of the stack is wired into the same brain, so the body is judged as one.
- **Who.** The operator who owns the system grants each wire, decides which knobs Omni may write and which it only watches, and keeps the kill switch. The governor writes only what it was granted; the native controller keeps doing its own job.
- **When.** Watch first: the governor reads every wire and writes nothing until the wire check passes and paired runs on the operator's own system show the receipt. Then one level at a time (the eight levels, Part Five). It reads and decides once a second, all the time; staying native is a live decision, made again every second, never a setting left on.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **How.** The plug snapshots each setting once, at the start; the brain reads every gauge, places each muscle on its compass, tries one step on one muscle at a time inside a body, keeps it only if the verdict shows a GAIN and no LOSS, and hands every setting back to the snapshot on reset, on the lease after a crash, or at once on the kill switch. The proof is the receipt: native and Omni on the same work, every gauge, three runs, every row shown.

What the end result is. A system fully hooked up runs native exactly as before, with one governor reading every gauge of every muscle once a second and moving, muscle by muscle, only where a paired trial has shown a GAIN with no LOSS anywhere in the body; where it cannot help, the muscle stays native, which is STEADY, not a failure. The intended outcome, stated as the claim the receipts test: more work, faster, with fewer misses, on the same or fewer machines, with every unit of power given shown beside what it bought. Whether a given system gets there is answered only by its own receipts.

Disclosures, Declarations and Disclaimers

This page is the one place every declaration about Omni-Compass is made. The README, the manual, the book, every guide and every report point here. Where any other page seems to say more than this page, this page governs.

1. Rights

1. Omni-Compass, its engine, its mathematics, its software and its documentation are the property of The Omni-Compass LLC. All patents, copyrights and trademarks covering them have been filed in the United States by Dubra Software Inc. / The Omni-Compass LLC. No filing number is stated here, and no grant, registration or approval is claimed.
2. The software is licensed for evaluation and simulation only (`LICENSE`). Running it in production, on any system beyond evaluation, or in any product or service, requires a signed, paid Omni-Compass Enterprise License.
3. Names of other companies and products (NVIDIA, Kubernetes, Red Hat OpenShift, Amazon EKS, Google GKE, Microsoft AKS, Karpenter, Lambda and others) are the property of their owners. They identify the systems Omni-Compass was tested with or connects to. No affiliation, endorsement or certification by any of them is stated or implied.
4. All rights reserved. Dubra Software Inc. / The Omni-Compass LLC reserves the right to change the software, the documentation, the results and the terms at any time, without notice. Every copy, fork, export, report, archive or printout of any part of Omni-Compass carries the README's notice, `LICENSE`, `NOTICE` and this page unchanged. Dubra Software Inc. / The Omni-Compass LLC, www.omni-compass.com

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

2. What a result is, and what it is not

1. Every result carries its evidence class: **T** a theorem, **V** verified in code, **S** our own models (modelled), **L** live software (real Kubernetes on GitHub's machines), **P** a physical meter (a real card's own power meter). A model is a statement about the model. A software benchmark is a statement about the software and machine it ran on. Only a meter speaks for hardware.
2. The models were written by the same people who wrote the law. They show how the mechanism behaves; they are not an independent test.
3. On Kubernetes in kind every machine stays powered, so energy there is a declared model, not a meter; on the data stores it is the host's processor seconds. Neither is scored in the Omni index: energy is scored only where a meter read it (the card's own meter), and every benefit is claimed at the software end (the founder's order of 31 October, evening).
4. Every comparison is paired: the same seed, load and clock with and without Omni-Compass, in an order rotated by repetition. Intervals are 95% intervals over the paired repetitions. Ratios across seeds are summarised as geometric means. Labels are assigned by code from rules written and committed before the run (`docs/GPU_PREREGISTRATION.md`, `docs/REALMS_PREREGISTRATION.md`, `docs/K8S_COMPASS_PREREGISTRATION.md`), never by hand.
5. Losses and failed runs are kept beside the wins (`docs/EVIDENCE_LEDGER.md`, `results/live/`, git history). The first real-card run, for example, read GAIN on its energy (the work per energy up 3.6%, its interval clear of zero) and LOSS on its slowest answers (the 95th percentile 58.5% slower); it is published as it happened (`results/gpu/run-20261002T082232Z/GPU_REPS.md`, `docs/EVIDENCE_LEDGER.md`).
6. No result is a promise of a saving on any other system. No dollar figure in this repository is a measured result. Nothing here is a vendor certification, a safety certification, legal advice or investment advice.

3. Do no harm, and the rule Omni-Compass keeps on every muscle

What "do no harm" means (the founder's words of 19 October 2026; this is its meaning everywhere in Omni-Compass, and it has no other). Omni-Compass has one goal: to strengthen the organism it governs and keep it healthy, working at the best state its own muscles can carry. Whatever is fed into the organism (its work, its data, its energy: its nutrients) passes through its muscles and comes out as its output. Omni-Compass's brain drives the organism toward the most and the best output it can make from what it is fed (the most work, done fastest, with the fewest misses and failures) while it keeps every muscle healthy.

- **Harm is judged at the organism.** Harm is the organism turning out less than its native controllers make it turn out (less work done; more time waited, missed or failed), or the organism made less healthy: a muscle pushed past its own limit, a service pushed over its own line, or anything made to fail. Omni-Compass does neither.
- **Every muscle only as far as it can go.** Omni-Compass can push a muscle only as far as that muscle itself can be pushed: its own limit, read live from the system, never past it. It finds the room each muscle

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

already has and uses all of it. Whether its mathematics can draw a little more out of a muscle than the muscle was built to give is an open question; a measurement answers it before anything is claimed.

- **The muscles work as one body.** Where one muscle's strength cannot be used without straining another, the brain offsets and engages the muscles together to bring the whole organism to its best state. It may use one muscle less, leave it native, or rest it, so that another can carry more, whenever the organism's whole output comes out ahead and every muscle stays healthy. Which muscles to drive and which to leave native is the brain's live decision, at every moment and in every run.
- **Reactive and proactive.** Like an immune system, the brain answers a breach at once, and it acts before a line is crossed.
- **Every row is still shown.** Each muscle's and each gauge's reading stays in every table beside the organism's, LOSS included. Nothing is cut.

How the engine that stands keeps it. The engine that stands keeps do no harm in its strictest form. By default it moves each muscle's settings toward more work, faster, up to the muscle's own limit and never past it (the max); on the dial anyone can tune it down toward the same work with less (the tune-down). Either way it keeps a step only where the muscle is never behind native for it: a step that costs the muscle more for each piece of work, or loses more than **2%** in any measure (work done, response time at the median, p95 or p99, time over the service line, or the machine's own cost of running Omni-Compass), is undone. A resource spent that rose is **power given**, shown beside the work, the speed and the wear it bought, never called a loss. Where no move passes that test, Omni-Compass leaves the muscle exactly as it runs alone. It takes nothing from one muscle to give to another: that form never harms the organism, but it leaves unused any gain that needs one muscle to give way to another. Letting one muscle give way so that the organism's whole output comes out ahead, judged on the organism and on every muscle's health, is the next engine version's work. It is built and proven in our own models first (the model gate), every benchmark is run again on it, and no result claims it before its runs exist.

The factory tune: one tuned engine, and a tuning bench. The engine in this repository is presented as Dubra Software Inc. / The Omni-Compass LLC tuned and ships it: self-running, set at the factory. Every muscle in the catalog is wired and runs on the setting found for it (its own card where one was found on development seeds and kept under the strict rule, 364 muscles in `realms/muscle_cards_v5.csv`; the engine's own setting for every other), frozen and fingerprinted by version (`python3 tools/omni_version.py`); no setting is presented as universal. **Every published benchmark result is one engine at its one factory tune**: the engine its table names (`python3 tools/omni_version.py`), run again on each engine that stands. From omni-v17 that tune is held to a declared rule (`docs/THE_TUNE.md`, `tools/tune_study.py`): of the tunes that harm no gauge against native, the one against which no other tune tried reads GAIN on one service gauge and LOSS on none, searched on development seeds and read again on untouched ones; the claim is non-dominance among the tunes searched, never a global optimum. The live benchmark engine page and the control panel are a live tuning engine: every knob, button and monitor turns in real time (the beat, the dial, the pedal, each muscle driven or left native, up or down, in or out, minus or plus) to show the mechanism of action with native alone, with Omni-Compass on

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

top, or both side by side; what it shows at any other setting is the engine's range, never a benchmark result. As on any engine, where the mixture, the intake, the exhaust, the firing or the pistons change what it delivers, **turning any knob of Omni-Compass can change every metric, up or down, in any direction a tuner chooses**: one engine for many vessels, tuned many ways, for many outputs. A licensee may add on, retune, upgrade or tune down any muscle or combination (the dial, the cards, the bands and the service lines are exposed); a changed tune is the licensee's own, and so are its results. The factory tune is published only where it reads no LOSS: a LOSS found in Dubra Software Inc. / The Omni-Compass LLC's own runs is treated as a fault in the mechanism or its wiring, found and fixed before the result is published, never as a number to live with (the founder's order of 23 October 2026). The one place a LOSS is meant to be seen is the live benchmark engine, when a person turns its knobs away from the factory tune (the dial, the heartbeat, the sizes, the load) to watch the system react and the brain hold or recover: that showing is the proof that the factory tune is the best state found, and that a turned knob never breaks the engine: it changes its mechanism of action, how its muscles and the organism share the work, toward the purpose the new setting asks for, and a changed tune's readings are the licensee's own.

The factory profile, and the profile that comes next. The factory tune is one complete configuration profile, the factory profile: every governing rule, gain, margin, decision interval and default setting shipped together, versioned and fingerprinted. Today's is omni-v19's. The best validated factory profile for the declared operating conditions is not yet established: it is chosen only after every mechanism is verified, every knob combination is tested together on development workloads, and the choice is validated on fresh ones; then it is frozen, carried into every implementation (the C++ harness included) and released under its own identity. Until then no other profile is presented as the baseline; on the live benchmark engine a candidate is evaluated, never released, and a custom profile's readings are its own. The words, the mathematics and the bill's arithmetic are written once in `docs/FACTORY_PROFILE.md`.

4. The wiring declaration

THE PUBLISHED BENCHMARKS ARE THE RECORD OF WHAT OMNI-COMPASS DID ON THE SYSTEMS, LOADS AND ENGINE THEY NAME, EACH WITH ITS EVIDENCE CLASS. WHERE A RESULT ON ANY OTHER SYSTEM DIFFERS FROM THEM, OR ANYTHING LOOKS WRONG, THE FIRST PRESUMPTION IS THE WIRING, THE SETTINGS, OR HOW OMNI-COMPASS WAS IMPLEMENTED OR READ, NOT THE LAW. CHECK THOSE FIRST (THE MANUAL'S "WIRED RIGHT OR WIRED WRONG") BEFORE DRAWING ANY CONCLUSION ABOUT OMNI-COMPASS.

Omni-Compass acts only through the wires it is given. It reads the meters it is pointed at and moves the settings it is allowed to move. If a reading is the wrong one, slow, or blind; if a lever is the wrong one, already owned by another controller, or given a range (cover) that is wrong for the machine; if a band or a service line is set for a different workload; then Omni-Compass will do exactly what its law says with the wrong information, and the result will not be the published one.

Therefore:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

1. **It cannot be slapped on.** Every installation goes through the levels of the manual in order (chapter 6), starting read-only, and every writing level begins with the wire check (manual, section 42.4) and a watch arm that must equal native.
2. **If your paired receipts differ from the published benchmarks in direction** (service LOSS, or no saving where one was shown), **the first presumption is wiring, not the law.** Confirm the installation with the checks in the manual's section 42.5 (*Wired right or wired wrong*) before drawing any conclusion about Omni-Compass.
3. **This has happened to us, and is published.** On the first real card (NVIDIA A10, 2026-10-02) the governor read being busy as trouble, set its power lid under the card's own working draw and allowed the clock under the card's own working clock; the card served bursts more slowly and the slowest answers were 58.5% slower. The cause was found in the card's own samples and corrected (`docs/GPU_PREREGISTRATION.md`, amendments 6 and 7). That is what a wiring fault looks like, and how it is found.
4. Omni-Compass never writes outside a lever's cover, never fights another writer (it stops and leaves that lever alone), reads back every write, and returns every lever to the value it read before its first write when it stops or when the OFF switch is used. These protect the machine; they do not make a wrong wiring right.

5. Safety and responsibility

1. Run watch mode first; run the wire check before any write; keep the master OFF switch (`python3 tools/omni_switch.py off`, the whole harness at once) in reach at every level, and use it at the first sign of anything wrong, a suspected breach included.
2. Omni-Compass is a supervisory governor. The machines' own controls (firmware, autoscalers, safety systems) stay in place and keep their own protections; Omni-Compass sets only values they already accept.
3. Do not connect Omni-Compass to safety-critical systems (vehicles, medical devices, grid protection, life safety) except as a modelled study, and never without the qualified review those systems require.
4. The software is provided "as is", without warranty of any kind, as stated in `LICENSE`. The operator is responsible for its use on their systems.

6. Changes to the work and to this page

1. The software, the law's settings, the benchmarks, the results, the documents, the licensing terms and this page may change at any time, without notice. The version in the repository's `main` branch at a given commit is the version that commit describes; `RELEASE_MANIFEST.json` and `python3 verify.py` identify it.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

2. Statements about work in progress, planned features, expected results and future runs are expectations, not promises. Where a result has not yet been measured, the documents say so (`docs/STATE_OF_PLAY.md`, `docs/DOSSIER.md`, section 8).
3. A signed Omni-Compass Enterprise License governs its own terms for its own term.

7. Privacy and data

Omni-Compass contains no telemetry. It sends nothing to Dubra Software Inc. / The Omni-Compass LLC or anyone else, and makes no network connection of its own except to the systems an operator points it at. Its logs and receipts stay on the operator's machines.

8. Where everything is

Question	Page
What has been measured, and how strongly	`docs/STATE_OF_PLAY.md`, `docs/DOSSIER.md`, `docs/EVIDENCE_LEDGER.md`
The rules written before each run	`docs/GPU_PREREGISTRATION.md`, `docs/REALMS_PREREGISTRATION.md`, `docs/K8S_COMPASS_PREREGISTRATION.md`
How to wire it, level by level, and how to confirm it is wired right	`docs/OMNI_COMPASS_MANUAL.md` (chapters 4 and 6), the book `docs/OMNI_COMPASS_MANUAL.pdf`
The license, in plain answers, and third-party components	`LICENSE`, `LICENSING_FAQ.md`, `ENTERPRISE_LICENSE.md`, `NOTICE`, `THIRD_PARTY_NOTICES.md`, `PATENTS.md`, `TRADEMARKS.md`, `SECURITY.md`, `.github/CLA.md`

Question	Page
The whole organism, composed every way it is bought	`results/WHOLE_SYSTEM.md`, `tools/whole_system.py`, `docs/engine/export_whole.py`, `docs/WHOLE_SYSTEM_PREREGISTRATION.md`
The Python's runs that the live benchmark engine runs again	`tools/engine_runs.py`, `results/engine_runs/`, `results/heldout_seed_*/`

9. The whole organism, the cloud's back end, and the live benchmark engine

The composition is a model of measurements. `results/WHOLE_SYSTEM.md` (`tools/whole_system.py`) composes each layer's own measured ratio, native against Omni-Compass on top of native, into one benefit for a whole stack: the product law $R(g) = \prod_\ell R_\ell(g)$ gauge by gauge, its logarithm a sum with the variances added, each layer's runs A, B and C pooled by the inverse of their variances, and one index over the gauges with its 95% interval under two bounds (the gauges independent; perfectly correlated). No run here has stacked the layers: each factor is one layer's own run with the layers under it native, and the product assumes a layer's ratio does not change when the layers around it also carry Omni-Compass. That assumption is tested where the tables can test it (the governors' four ways), and the stacked run that replaces the composition is preregistered in `docs/WHOLE_SYSTEM_PREREGISTRATION.md`. Until it runs, the composition is class S of class P and L measurements, and every page that shows it says so.

The two places a system runs. The same law is read in the two places a system runs Omni-Compass (the founder's order of 1 November 2026; `docs/engine/export_whole.py`): the software end carried to bare metal (the software on the owner's own machines and chips), and the software end carried to the cloud (the cloud's build, its bare metal at the back end and the software; and the cloud as two pieces, the back end left to the provider). A piece with no measurement in the composition enters as exactly 1 and is named; neither place's composition is that place's bill. The bills themselves, and the work done inside them, native and Omni-Compass on native (the four arms: A and B on bare metal, C and D through the cloud), are read in `results/TWO_BILLS.md`.

The cloud's back end is not ours to meter. Through the cloud, the bare metal belongs to the provider: no tenant can read its power meters or write its chips' limits, and no run here reaches it. The cloud piece's benefit is what the provider itself meters and bills, the machines counted every fifteen seconds and the bill at list price, read native against Omni-Compass on top of the cloud's own autoscaler. The bare-metal piece is gauged on hardware we can meter (a card's own power meter; a processor's energy counter) and is carried to the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

provider's bare metal only as the same mechanism on the same kind of part, a modelled factor, never as a measurement of the provider's machines.

The cloud is a wire. A cloud is the wire between the software end (the owner's programs, Kubernetes and the open-source orchestrators, managers and autoscalers that carry the work) and the hardware end (the bare metal: the GPU chips, the Linux racks, the data center). Omni-Compass sits on all three pieces where a system lets it (the software end in either place, the chip only on bare metal); a system itself runs in one of two places, bare metal or the cloud (the founder's order of 1 November); the wire makes no benefit of its own. Until 31 October every cloud run here was set on the wire alone (the tune-down on the machines only), so it could at most park machines the cloud already made and cut the wire's bill a little. From 31 October (the founder's order of that day: no hard rule) every cloud set runs the whole engine at the max on the cloud's cluster, and what its receipt must show is that the engine holds there (section 10): no judged gauge LOSS against native, the work per dollar read beside the bill. The benefit is shown where it lives, at the software end, and explained through the wire, never claimed for the wire itself. The bare metal's energy and throughput are not under a tenant; they are measured where Omni-Compass sits on them (the card and the machine) and composed with the wire by the law above. A provider running Omni-Compass on its own back end would see that benefit on its own chips and racks; no tenant can meter it, so it is never claimed here as a measurement. No place carries a figure before its runs read it (the founder's order of 2 November: no number on any page that no table carries), and his word of 31 October sets the wire's own benefit at none: the wire carries the benefit, it does not make it.

What the record shows in each place so far (the words for each place, and what each benchmark must show, are in section 10): at the software end the benefit, the Omni index over work, speed and machines (`results/OMNI_INDEX.md`; composed layer by layer in `results/WHOLE_SYSTEM.md`), with no bill in it; on bare metal, the A10's own bill and meter on omni-v23 (`results/TWO_BILLS.md`, `results/gpu/V23_A10_CAP_FULL_ABC.md`), fully loaded: the bill STEADY, the work done inside it the runs disagree (up in two runs, down in the third, that run's lost work on the next version's list), the chip's energy for each request served GAIN in all three of our runs (the A100's three runs on omni-v21 read work and energy STEADY, `results/gpu/V21_A100_CAP_ABC.md`); through the cloud, Azure's steady set on omni-v18, 97 paired repetitions (`results/live/AKS_STEADY_100_OMNI_V18.md`) reads the bill up 1.2%, inside the noise, power given; the 99th percentile GAIN, down 11.0%; and failed requests up 3.9% by the mean (4.758% to 4.945% of requests), its interval across zero: a LOSS by the 0.5% key, inside the noise, on the next version's list. No gauge moved against native beyond the noise; by the key the set does not yet read that it holds. What the benefit cost the chip, the energy and the wire is listed row by row in section 3b of `results/WHOLE_SYSTEM.md`. In the cloud the yardstick is the work per dollar: the work answered within the line divided by the bill, against native; a bill that rises is power given beside the work it bought, and the work must rise more.

The four arms (the founder's order of 1 November): every place is read by its bill and the work done inside it, native against Omni-Compass on native: **A** and **B** on bare metal (the chip), **C** and **D** through the cloud; the seven organisms run both ways in each place, fourteen runs a place, every organism at every size in

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

`results/TWO_BILLS.md`, a place not yet reported naming the runs that will fill it. On omni-v23 so far the A10's compute run at the usual load reads every gauge STEADY (`results/gpu/V23_A10_FAST_ABC.md`); Google Cloud and Amazon Web Services are not yet run (their keys are not in the repository's secrets).

The organisms. The seven organisms of the catalog (the spine, the four realms, the four stacked, the tower), the orchestra beside them, the live benchmark engine's own sixty-muscle organism, and the whole organism in its three pieces (the software end, the cloud's wire, the bare metal) composed above: ten organisms. Each is read two ways, native and Omni-Compass on top of native (Omni-Compass is never by itself, the founder's order of 25 October): twenty scenarios, recorded in `results/scenarios/SCENARIOS_20.json` (class S, our own models, three runs), every cell with no run reading "not yet run". None is a product.

The live benchmark engine. `docs/engine/OMNI_COMPASS_LIVE_ENGINE.html` is a monitor of the repository's records and of the engine's own mathematics running in the page, and the live tuning bench: a setting other than the factory profile shows a variation of the mechanism, never a result. Every monitor carries its evidence class (P a physical meter, L live software, S our own models) and its state: live (the engine's port, proven equal to the Python and the C++ on every build by `docs/engine/check_live_engine.py`), a replay of a recorded run from its own files, a reading of the repository's tables, or built and awaiting its run, with no invented number and the run that fills it named. The kill switch on the page acts on what runs in the page, and a recorded result changes its colour, never a value, a word or a row. Pointed at an owner's own Prometheus, the page only reads it: it writes to no system.

The three manuals. The Operator's Manual wires and runs Omni-Compass, the Owner's holds the whole mechanism and every result, the Live Benchmark Engine Manual reads the page; each carries this notice, the `LICENSE`, the `NOTICE` and this page.

10. Where Omni-Compass sits, and what each benchmark shows

Omni-Compass is software. It always sits on top of a native controller. A system runs it in one of two places, on bare metal or through the cloud, and in each place there are two arms, native and Omni-Compass on top of native: four arms, each read by its bill and the work done inside it. These are the words for them, used the same way on every page.

Place	Its benchmark	What it must show	Its readings
The software end	Kubernetes and the data stores on GitHub's machines (kind), class L	the benefit, by the one key, and that it holds	`docs/BENEFIT_SHEET.md`, `results/OMNI_INDEX.md`
Bare metal, the chip	a graphics card on Lambda run directly, its rental the bill and its own power meter beside it, class P	that it holds, and the work done inside its bill, A against B: the work per dollar and per joule	`results/TWO_BILLS.md`, `results/gpu/`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Place	Its benchmark	What it must show	Its readings
Through the cloud	Kubernetes through Azure's AKS, the machines it bills, class L	that it holds, and the work done inside its bill, C against D: the work per dollar	`results/TWO_BILLS.md` and each set's `results/live/AKS_*.md`
The whole organism	the places composed by the product law, class S of P and L	how the places add up, an explanation and never a measurement	`results/WHOLE_SYSTEM.md`

- **The software end.** The programs that carry the work: Kubernetes with its pod and cluster autoscalers, its schedulers and the orchestrators on it, the data stores (PostgreSQL, MySQL, Redis, MongoDB, Kafka) and the services they serve. Omni-Compass sits on top of their native controllers. This is where its benefit lives and where it is measured: real software on real computers (class L), on GitHub's own machines in kind clusters. Those machines are rented runners, never called bare metal and never called the chip.
- **Bare metal.** The first of the two places a system runs (the founder's order of 1 November 2026): the owner's own machines, or a chip run directly, with the chip's own controllers under the software. Its bill is the machine's own: the hours it runs, and the energy the chip's own meter reads. The software end goes with Omni-Compass to it, and there Omni-Compass can reach the chip's own knobs too.
- **Through the cloud.** The same software end on a cloud provider's rented machines: Kubernetes through the cloud (Azure's AKS today; Google's GKE and Amazon's EKS wired the same way, not yet run), the machines billed by the hour at list price and added or removed by the cloud's own autoscaler. Its bill is the cloud's own; the cloud's chips and back end are inside its price and out of Omni-Compass's reach: it governs what the cloud gives, through the cloud's own Kubernetes. The cloud is the wire between the software end and the provider's bare metal. The wire makes no benefit of its own, and no tenant can meter the provider's chips.
- **The chip.** Bare metal's own part: the processor or graphics card under the software, with its own controllers (the power limit, the clocks, the heat), measured with the card's own power meter (class P) where Omni-Compass sets the card's knobs through the card's published interface. Omni-Compass built into the silicon, or into a battery's own controller, is not something any run here can test, and it is not claimed.
- **The four arms.** Two places, two arms in each: A, native on bare metal; B, Omni-Compass on top of native on bare metal; C, native through the cloud; D, Omni-Compass on top of native through the cloud. Each is read by its bill and the work done inside it, each place on its own, since a system runs in one or the other; an owner who runs work in both may weigh them only by its own spend, through G(total) (`results/TWO_BILLS.md`, `docs/WORK_PER_BILL.md`). The software end's tests are one set read three ways (the Omni index on work, speed and machines; the same on work and speed alone; the layers composed): they never add together, and none of them is either place's bill.
- **Hold.** Omni-Compass on top of native harms nothing in that place: every judged gauge (the work done, the response time, the minutes over the line, the pods waiting, the failures) reads STEADY or GAIN

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

against native by the one key, and a resource that rose (the bill, the machine-hours, the energy) is read beside it as power given. A place holds when its runs read no LOSS.

- **Where the benefit lives.** At the software end, where it is made and measured, with no bill in it. It shows through on the two bills, native against Omni-Compass on native: on bare metal the work done inside the machine's own bill (each dollar, and each joule of the chip's own meter), and through the cloud the work done inside the cloud's own bill (each dollar). The chip and the wire themselves add no gain of their own: they are where Omni-Compass must hold. A benchmark that holds is the proof of no harm in its place; the benefit is shown where it lives and explained for the rest.
- **Work for the bill.** The one number every receipt is read for: the work done for each dollar of the bill, $E = W / B$ (written once in `results/TWO_BILLS.md`), in each place native against Omni-Compass on native, $G = E(\text{Omni-Compass on native}) / E(\text{native}) - 1 = (1 + \Delta W) / (1 + \Delta B) - 1 \approx \Delta W - \Delta B$, ΔW the change in the work done and ΔB the change in the bill. A bill that rises is power given; there is more work for the bill when the work rises more than the bill ($\Delta W > \Delta B$, $G > 0$). Both arms pay the same prices, so a place's price level cancels in its G. A system that runs in one place reads that place's G alone; an owner who runs work in both weighs them by its own native spend $S(p)$, $G(\text{total}) = \Sigma_p S(p)(1 + \Delta W(p)) / \Sigma_p S(p)(1 + \Delta B(p)) - 1$ (`docs/WORK_PER_BILL.md`).
- **One mechanism, in one place, felt along the whole path.** Omni-Compass acts in one place, the software end, on top of the controllers a stack already runs; it changes nothing in the chip and nothing in the network or the cloud. Its effect travels the whole path the work travels: a request starts in the software, crosses the wire (the owner's own racks or a cloud's machines), is computed on the chip and comes back. So the effect is checked at every place: the software end shows the gain (more work, faster, the machines it took read beside it, a rise power given), and the wire and the chip are read for whether it holds and carry the gain to their bills. Two places are tested because a system runs in only those two; one mechanism makes the gain, the way a city's traffic signals make more trips an hour on the same roads and the same cars.

Never in the data path. Omni-Compass never touches the data a system serves: no request, packet, file or byte of the work passes through it, and it never opens, reorders, compresses or caches that data. It reads the system's gauges (one wire in) and writes the settings the native controllers already accept (one wire out). A description that puts it in front of the data, as a pipeline, a packet scheduler or a compressor, is not a description of Omni-Compass. Where it sits among the industry's answers at the chip, the cloud and the software is on `docs/INDUSTRY_LANDSCAPE.md`; no figure there or anywhere is Omni-Compass's unless one of this repository's tables carries it.

Quick Reference: The Card for the Glove Box

Keep this page where the people who run the system can reach it, the way a driver keeps the card in the glove box. Every line is explained in the section named beside it; nothing on this page replaces those sections.

What it is. A supervisory governor on top of the controllers you already run. It never replaces them: it moves only settings they already accept, inside a band you set, and hands every setting back when it stops (section 1.1 and chapter 42).

The three arms. *Native* is your system as it runs on its own. *Omni*, Omni-Compass on native, is the same system with Omni-Compass on top. *Omni-Compass direct* is the same system with each knob's native controller switched off and Omni-Compass the only controller moving it; never in a cloud without the owner's word. There is no other arm and no other name (section 1.1).

The profile and the two restoring controls (section 76.8). Start on the factory profile; every change makes a custom profile, its results its own. **Restore factory profile** reapplies the released configuration. **Return to native** is the reset: every setting handed back to the snapshot, read back, the governor stopped. The kill switch is separate, for security only, and instant.

The modes (section 1.3).

Mode	What it does	When
Off (manual)	nothing; native runs alone	before installing, and whenever you choose
Watching	reads every gauge and logs what it would do; writes nothing	the first level of every installation (level 1)
Autopilot	one pedal: push for more, lift off for less, idle (lifted all the way) and reset, by its law	after the watch level has passed
Cruise	machines in service up to the pool's own top while a known queue waits	batch work

One pedal, like an electric car's. *Push*: capacity added at once as traffic climbs, never held back. *Lift off*: capacity eased off a step at a time, handed back toward native, never below idle. *Idle*: the pedal lifted all the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

way, the floor of two machines in service, ready for the next burst. *Reset*: every setting handed back to where native had it, read back, and the record removed.

The ways it stops, and what each leaves behind (Chapter 49).

You want to, or it happens that	Do this	What is left
a run ends	nothing: the reset runs by itself at the end of every run	every setting at the operator's value, read back
stop everything at once, for any security reason	`python3 tools/omni_switch.py off`	every governor hands back and exits; none starts again until `python3 tools/omni_switch.py on`
stop one muscle	its kill file, or `OMNI_KILL=1`	that muscle handed back; the others run on
Omni-Compass dies without handing back (killed, crashed, hung)	nothing: the watchdog's lease hands back for it	every setting back at the operator's value, measured at 7 to 11 seconds in 30 of 30 repetitions (section 76.5)

The eight levels of an installation (section 45.3). Take them in order; go to the next only when the pass holds.

Level	What it touches	Pass
0	nothing: `python3 verify.py`	`VERIFICATION: PASS`
1	nothing: watch mode, with a read-only identity	zero writes, and readings your operators agree with
2	the pods, through your autoscalers (**WRITES**)	p95, p99 and failed requests never behind native, over paired runs
3	the machines, through the release gate and the verdict (**WRITES**)	fewer machines in service, with no LOSS on any service gauge
4	the replica decision itself (an option, not a step)	as level 3
5	a GPU box, two wires: the clock ceiling and the power limit (**WRITES**)	work per energy up or equal; no request more than 2% slower at the median, p95 or p99
6	the processor's clock and power on bare metal (**WRITES**)	energy per unit of work down, no LOSS on any service gauge

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Level	What it touches	Pass
7	site power and the supply-air setpoint (**WRITES**)	the site meter's energy down, every rack inlet inside its band, no LOSS on any service gauge (section 46.11)

Before any level that writes: run the wire check (section 42.4), start in watch, and keep the master switch in reach.

Warning signs, and the first thing to do.

You see	First	Then read
a service slower or failing more with Omni than without	`python3 tools/omni_switch.py off`: the system is native again	section 42.5, wired right or wired wrong
a setting at a value Omni-Compass did not write	nothing: it stops writing that lever by itself (one writer)	section 32.2
a meter that is blind or late	nothing: blind means hold; it moves nothing it cannot see	section 32.3
your results point the other way from the published ones	presume the wiring first, not the law	`DISCLOSURES.md`, section 4

Who to call. Licensing, pilots and the Omni-Compass Enterprise License: Dubra Software Inc. / The Omni-Compass LLC, main office infrastructure, toll-free direct 1-888-339-9551, system route asset 1-888-DEX-YLL-1, landline 321-746-4411 registered in Florida, www.omni-compass.com. Security reports: the process in `SECURITY.md`, never a public issue.

What the letters of the number mean. Read as one sentence: Omni-Compass takes the system in through a Data Exchange (DEX), runs every setting up to its Yield Limit Line (YLL) and never past it, and closes it all into one loop (1); science and software people read each part on sight. Read in order, DEX-YLL-1 is the way the engine runs:

Letters	What they mean
DEX	**Data Exchange**: the input. In software, data exchange is how one system's readings reach another. Here it is the two-way plug, one wire in and one wire out: the system's own readings come in, Omni-Compass's settings go out.
YLL	**Yield Limit Line**: the boundary. In engineering science, the yield limit is the most load a material can carry and still spring back unharmed; past it, the damage is permanent. Omni-Compass runs every muscle up to its own yield limit line, read live, and never past it.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Letters	What they mean
1	**1**: the output. In code, 1 is true, the finished state; in science, 1 is unity, the whole. Here it is one closed loop: one body, one brain, every result read back and the next step decided from it.

Executive Summary

What it is. Omni-Compass is a supervisory governor. It sits on top of the controller a system already has, the Kubernetes autoscaler, the GPU's firmware, the cooling loop, the battery inverter, the robot's servo, the grid's tap changer, the database's connection pooler, the message broker's consumer group, the cache's memory ceiling, and it moves only the settings those controllers already accept. It reads each muscle's own meter, computes one bounded force per muscle from a single smooth law, and holds the service in the middle of its safe band rather than far below its limit. The native controller keeps running exactly as shipped; Omni-Compass sets what it already exposes, and when Omni-Compass stops, every setting goes back to the value it read once before its first write. It is never standalone and it never competes with the controller underneath it.

What it does for you. Every running system keeps room "just in case": machines sized for the worst minute of the day, a pool of connections held open for a load that comes once an hour, a consumer group sized for the quiet hours and then overrun at the peak, a cache ceiling set once and left. By default Omni-Compass turns that room into more work, faster: the max, every muscle run up to its own limit, read live, never past it and never below native, the energy it takes shown as power given beside the work and speed it bought. On the dial, anyone can tune it down to the same work with less. The two are the same measurement read from two sides (section 76.4): a third more work from what is already installed is a quarter off the bill.

Where things stand, read from the result files. Written by `python3 tools/summary.py --fix` from the files it names; `verify.py` fails a push in which this block no longer matches them. Nothing in it is typed by hand. The live results run on the engines named in their own tables, and every one of them runs again on the newest engine.

- **The engine on this checkout:** omni-v26, fingerprint 75d3c22eed4473b9 (65 files).
- The muscles and the seven organisms on engine omni-v8 at the max (evidence class S, our own models; run 2026-10-17 15:39 UTC, commit 9819a903cba3, 1107 muscles; source: results/realms_v5/REALMS_V5.md):
  - every muscle alone, over its loads: STEADY 577, GAIN 530
  - the organisms under the normal load: the spine: GAIN (fewer misses), misses down 0.145 pp, energy STEADY, up 0.011% (under the 0.5% floor); Compute / AI / Cloud: GAIN (fewer misses), misses down 0.070 pp, energy STEADY, up 0.009% (under the 0.5% floor); Physics / Robotics /

Benchmark	Engine	Its one number	Its word	Class
Buildings and batteries (CityLearn), the districts with batteries	omni-v26	1.4%	GAIN	S
Kafka, the consumer group's size	omni-v26	221.1%	GAIN, power given	L
The six organisms with the real cluster inside, 10 and 100 copies	omni-v3	5.3%	GAIN, power given	L, the cluster; S, the organism around it
The big organisms with the real cluster inside, 1,000 copies on Azure	omni-v3	155.0%	GAIN	L, the cluster; S, the organism around it
The 945 modelled muscles as one tower, every muscle written at once	omni-v3	0.3%	GAIN	S

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

What has not been shown, said plainly. An energy or cloud-bill saving on real machines. Energy on kind is a declared model, because the machines are containers on one runner. Azure's bill on a 4-worker fleet read no difference beyond the noise on every gauge, which is the honest reading of a fleet too small to show one machine; the 40-worker fleet that can show one is preregistered and has been refused by Azure's own cluster capacity in its region, each refusal recorded. Every earlier GPU result ran on a controller since replaced and is obsolete; the card runs again on rented hardware at one named commit. Each of these is an open item in Chapter 60, not a footnote.

How it stays safe. It watches before it writes. It records every original setting before it acts and reads back every write. It never writes past a knob's cover. It gives everything back the moment service crosses the wall or a sense goes blind. It stops writing a knob the instant anyone else touches it. It moves a slow knob only after a paired trial on the muscle itself shows no more than 2% cost. One OFF switch returns every setting to its original value; a watchdog with a lease does the same if the governor is killed outright; and a separate kill switch, for security only, turns the whole harness off in one human hand.

How you know. Every run produces receipts: native against omni on the same system, the same load and the same clock, each gauge with its 95% interval, the raw files archived beside the code and fingerprinted. Results are labelled by a rule written before the run, read across all three of our runs by the one key (a change of 0.5% or more is a change), and reported with every loss in the table.

PART ONE

The Philosophy and the Theory

Where Omni-Compass comes from: the closed circle, the four pieces, the compass, the basins and the reflex. The engineering in the rest of the book is this idea made exact.

CHAPTER 1

What Omni-Compass Is

A governor on a steam engine does not build the engine and does not turn the shaft. It watches the speed and moves the throttle so the speed stays in a band. Omni-Compass is that, for every machine you run.

It is a process on a host. It reads meters, steps a bounded mathematical law, and writes only the levers it has been given. It is not the chip, not the GPU driver, not Kubernetes, not the building controller. Those keep running exactly as they do today; Omni-Compass sets the values they already accept.

Three facts about that process fix what the rest of this manual can and cannot claim. First, it is **one process per stack**, a controller (`omni_controller/controller.py` on a cluster; the harness's own controller on a database or a cache) that wakes on a fixed period, reads the stack's own gauges through the stack's own interface, decides, writes through the same interface, and reads back what the device took; it has no agent inside the pods, no kernel module, no hook in the request path, so it can add latency to nothing it does not govern. Second, every lever it may touch is **named before it starts**, read once into a snapshot, and handed back to that snapshot when it stops, is killed, or loses a sense; a lever it was not given it cannot reach, because the plug for it does not exist. Third, it has a **watching mode** in which it reads and decides and writes nothing, and every rollout begins there (Chapter 45): the first thing an operator learns about Omni-Compass on their own stack is what it would have done, in a log, with the stack untouched.

What follows from those three is the shape of the evidence in Part Seven. Because the native controller keeps running underneath, every benchmark is the native stack against the same native stack with Omni-Compass on top, and never Omni-Compass against anything else. Because the levers are the stack's own settings, every gain is one the operator could have reached by hand, if they had been able to read every gauge every few seconds and move every knob without ever being wrong; the claim is not a new mechanism but a steady hand on the mechanisms that exist. And because the process is small and separate, its own cost (CPU on the host, reads of the API) is measured in every run and counted against it where it shows.

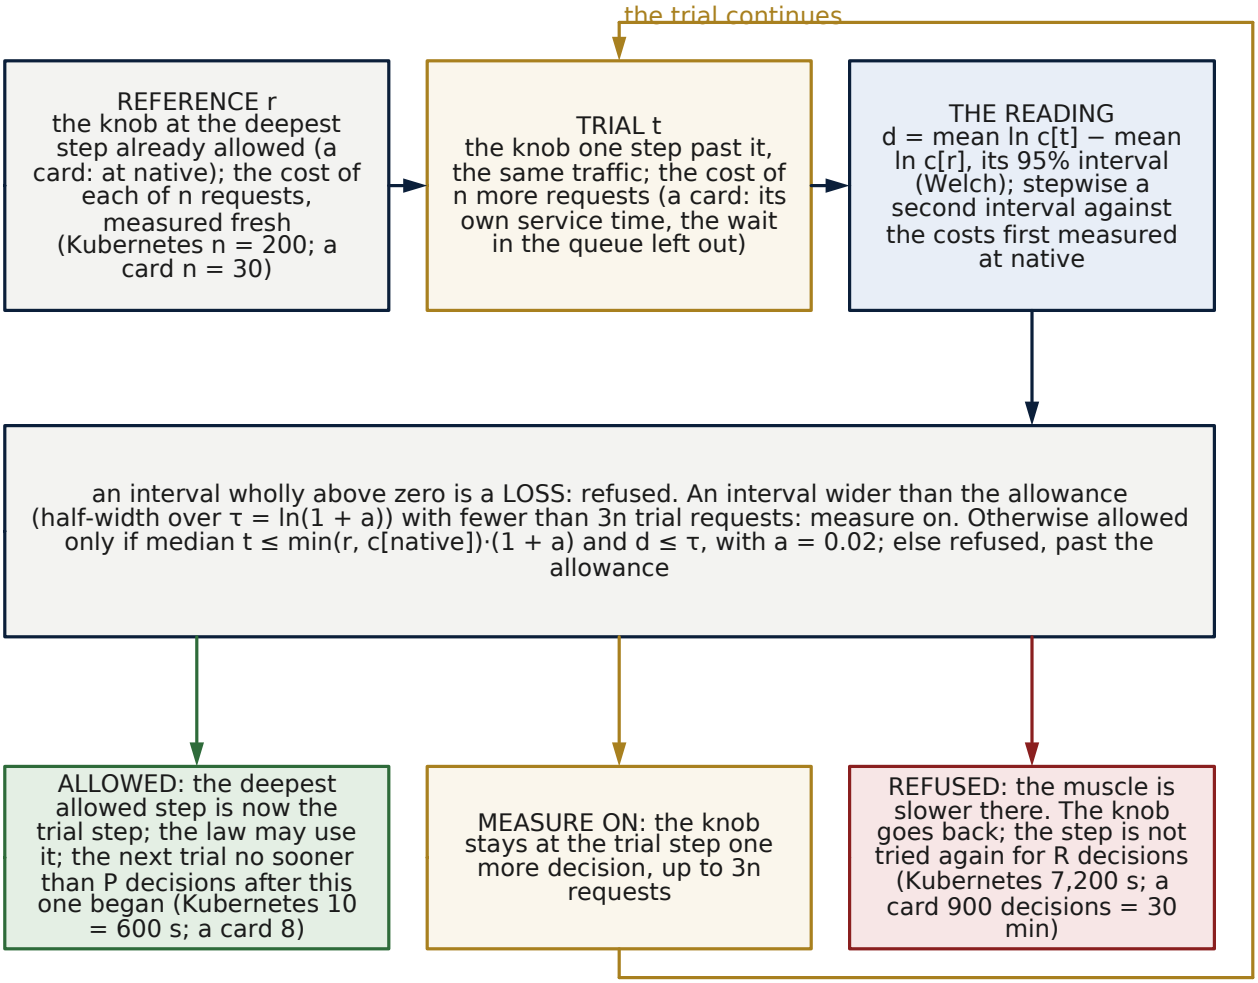
1.1 Always on top of a native controller

The first design decision, and the one every other follows from, is that Omni-Compass is **supervisory**. It never replaces the controller a system already has, never bypasses it, and never runs in its place. The Kubernetes Horizontal Pod Autoscaler keeps scaling pods on its own CPU target; Omni-Compass moves that target inside a range the operator allows. The cluster autoscaler keeps adding and deleting machines; Omni-Compass marks machines idle and lets the autoscaler do the deleting. The card's firmware keeps boosting the clock and enforcing its power limit; Omni-Compass sets the ceiling the boost may reach and the limit the firmware enforces. PgBouncer keeps handing connections to clients; Omni-Compass sets its pool size through the pooler's own console. Kafka's consumer group keeps rebalancing partitions on its own; Omni-Compass changes how many consumers are in the group, which is what an operator does. Redis keeps evicting by its own rule; Omni-Compass sets the ceiling that rule works under.

This matters to a referee for a precise reason: every benchmark in this manual sets **omni** (Omni-Compass on native: the same system with Omni-Compass on top) against **native** (the system with its own controller, as shipped and as the operator set it), and there is no comparison in which Omni-Compass on native is a rival to that controller. Since the founder's order of 23 October a third arm, **the arm by itself** (called Omni-Compass direct that day), runs beside them as a mechanism test: a knob's native controller switched off only where Omni-Compass carries that muscle itself and has proven it can move the knob, Omni-Compass then the only controller moving it, and every muscle Omni-Compass cannot be kept, native, under it. On Kubernetes that is Omni-Compass's own pod rule in place of the autoscaler's arithmetic and nothing else, because Omni-Compass is a brain with no organs there: it can be direct to a knob, never to a muscle (the founder's analysis of 31 October, `docs/SOLO_PREREGISTRATION.md` amendment 2; on Kubernetes the pod autoscaler removed where Omni-Compass's own pod muscle takes the workload, no cluster autoscaler on kind, the API server, the scheduler and the kubelet kept; `--own-replicas`, omni-v19; in the models `realms/harness.py` SOLO; Omni-Compass's own orchestrator, `omni_orchestrator/`). Where native is a setting rather than a controller, or its own loop is the actuator, the two Omni-Compass arms are one arm; no cloud runs direct without the founder's word (`docs/SOLO_PREREGISTRATION.md`). The three are always shown together, each pair read on its own. A gain is therefore always "what the governor added on top of what the native controller already did", and a loss is always "what the governor cost on top of it". Nothing in the record is an argument against any native controller; every native controller in this manual is a good controller that the governor sits on.

1.2 Do no harm: the verdict

The second design decision is do no harm, and its meaning is the organism's (the founder's words of 19 October 2026, `DISCLOSURES.md` section 3): the organism Omni-Compass governs is never left turning out less than its native controllers make it turn out, nor less healthy (no muscle past its own limit, no service over its own line, nothing made to fail), and within that the brain drives the whole organism to the most and best output its own muscles can carry, using one muscle less, or leaving it native, where that lets another carry more and the whole comes out ahead. The engine that stands keeps the rule in its strictest form:



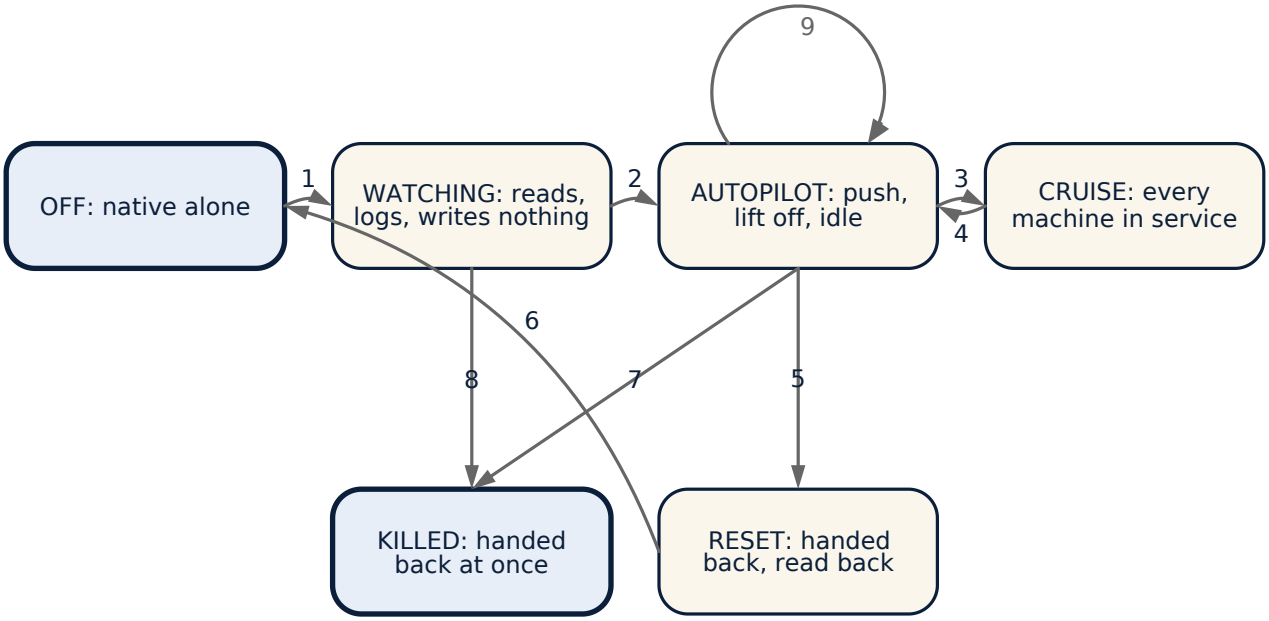
© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Omni-Compass must never cause a LOSS on any muscle, judged on the muscle itself, and takes nothing from one muscle to give to another; the trade between muscles, judged on the organism, is the next engine version's work. This is not a slogan printed on a report; it is a trigger inside the engine. Before Omni-Compass moves a slow knob (a machine given back, a card's clock ceiling, a robot axis's speed, a drone's cruise override), it runs a **paired trial on the muscle itself** (`omnicompass/verdict.py`): the muscle's own cost per piece of work is measured at the deepest step already allowed (on a card, at native) and at one step past it, under the same traffic, with a set number of pieces of work on each side (n = 200 response times on Kubernetes, `--verdict-samples`; n = 30 requests on a card). From v7 the trial is read in the reports' own words: on the logarithm of each piece of work's cost, the change d = mean ln c[trial] − mean ln c[ref] carries its 95% interval $d \pm 1.96 \cdot \sqrt{(s^2[ref] / n[ref] + s^2[trial] / n[trial])}$, and with $\tau = \ln 1.02$ the 2% allowance in the same units, an interval wholly above zero is a LOSS and the step is refused whatever the allowance says; while the interval's half-width exceeds τ the trial measures on, up to three times its minimum; and a GAIN or STEADY step is allowed only if its median cost and its mean-log change are both no more than 2% above the reference and above the cost first measured at native. On modelled noisy costs ($\sigma = 0.25$) this allows a step that truly costs 3% more 28% of the time instead of the medians' 40%, one that costs 5% more 14% instead of 26%, and a free step 60% instead of 63% (`docs/OMNI_V7.md`, section 3; class S). The engines before v7 read the medians alone (`judge="median"`). A refused step is not tried again for a set time (7,200 s on Kubernetes, 120 decisions at a 60 s beat, 120 at 10 s beat, 480 at a beat of 15 s; 900 decisions, 30 minutes, on a card); a trial begins only while the service is calm and nothing waits, no sooner than 600 s (a card 8 decisions) after the last began; and a phase that sees the service leave calm or outlasts its limit (1,200 s on Kubernetes; 30 decisions on a card) is abandoned, the knob goes back, and the step is neither allowed nor refused. Where no step passes, the verdict reads **left native**, the knob is never moved, and the result for that muscle says "nothing for Omni to move". This is why, in the robot-arm benchmark, two of four arms were left entirely native and are reported as such, and why in the real Kubernetes tests machines were kept whenever one machine fewer made the requests slower in the trial. Gains are not capped; the allowance caps only what may be spent to get them.

The same principle, applied after the fact to every published result, is the page of wiring verdicts (`docs/WIRING_VERDICTS.md`, section 16.6b): every knob in every table is given one of three words from the table itself, **write** where a gauge is GAIN in all three of our runs and none LOSS or power given in all three of our runs, **watch** where nothing is GAIN in all three of our runs (the knob stays native and Omni only reads it, one wire out and no wire in), and **operator's choice** where gains and losses are both the same in all three of our runs. Omni-Compass is wired out of every muscle; it is wired in only where it has earned it.

1.3 The pedals, the modes and the two switches

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.



The verdict stands over every slow knob (the machines, the clock ceiling, a cache's notch). A trial begins only while the service is calm and nothing waits; a phase that sees the service leave calm, or that takes longer than its limit (Kubernetes 1,200 s; a card 30 decisions), is abandoned and the knob goes back, the step neither allowed nor refused. The knob never passes the deepest allowed step, so steps cannot add up past the allowance. On the max, the Kubernetes machine count never gives back a machine the cluster had on its own.

Figure 1. Block diagram: the verdict's paired trial around a slow knob, read GAIN, STEADY or LOSS. The reference r is the cost of n requests at the deepest step already allowed (on a card, at native; n = 200 on Kubernetes, 30 on a card); the trial t is the cost of n more one step past it under the same traffic. The reading is the 95% interval of d = mean ln c[t] − mean ln c[r], stepwise also against the costs first measured at native: an interval wholly above zero is a LOSS and the step is refused; an interval wider than τ = ln(1 + a) measures on, up to 3n; otherwise the step is allowed only if median t ≤ min(r, c[native])·(1 + a) and d ≤ τ, with a = 0.02.

A refused step is not tried again for R (7,200 s on Kubernetes, 480 decisions at the 15 s heartbeat; 900 decisions on a card, 30 min). Steps cannot add up beyond the allowance, because every step is judged against the native cost too.

Omni-Compass drives a system the way a self-driving car drives itself: it feels, gauges and adjusts, with nobody in the seat. The vocabulary is used the same way everywhere in this repository (`docs/MECHANISM_OF_ACTION.md`, "The pedals"):

1 level 1 · 2 the wire check passed; level 2 and up · 3 pods waited 2 decisions · 4 the line empty 2 decisions · 5 the reset file: the end of a run · 6 exit 0 · 7 the kill switch, from any mode · 8 the kill switch · 9 idle at once when demand is at zero

Figure 2. State machine: the governor's modes. OFF is native alone; WATCHING reads and logs and writes nothing; AUTOPILOT pushes, lifts off and idles; CRUISE holds every machine in service while pods have waited two decisions; RESET hands every setting back and reads it back at the end of a run; KILLED hands everything back at once, from any mode, on the kill switch. The numbered transitions are read in the key under the diagram.

- **Off (manual).** Omni-Compass is not driving; native runs alone. This is the native arm of every benchmark.
- **Watching.** Omni-Compass reads every gauge and logs the decision it would take, and writes nothing. Any difference between a watching arm and native is the cost of its being there (its CPU, its reads) plus noise, never a decision; a watching arm that writes anything fails its run. Watching is the first level of every rollout (Chapter 45).
- **Autopilot.** One pedal: **push** (traffic climbs and capacity is added at once, never held back), **lift off** (traffic falls and capacity is eased off a step at a time, handed back toward native, never below idle), **idle** (the pedal lifted all the way: calm traffic, the engine at its floor of two machines in service, ready for the next burst), **reset** (every setting the governor ever wrote is handed back to where native had it, read back, and the record removed; every benchmark arm ends with a reset and checks it).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

- **Cruise.** For work that comes as a pile: when pods have waited for a place decision after decision for the cruise wait (120 s: two decisions at a 60 s beat, twelve at the factory's 10 s on site, and never fewer than two readings at any beat), machines go into service up to the pool's own top (read live: every machine of a fixed pool at once, a growing pool a step a decision) and stay there, without second-guessing, until the line has been empty as long. In cruise the governor also stops its five-second floor reads, because every machine is already in service and the reads would only cost CPU on the machines the queue is using.
- **Idle at once.** When the work is done and demand is at zero (the service at its autoscaler's own floor, wanting no more, at half its target or less), the pedal is lifted all the way in one move, straight to idle, with every safety check still holding.
- **The kill switch.** Separate from all of the above, and for **security only**: one switch in a human hand (`python3 tools/omni_switch.py off`, `omnicompass/master.py`) turns Omni-Compass's governing off across the whole machine at once, for anything rogue, or for anyone trying to drive a system through Omni-Compass's brain. Every governor hands back and exits; none starts while the switch is off. The reset is the end of a run; the kill switch is the end of trust.

The floor of two machines is an operator's number; lifting off never takes a system below it, however far the pedal is lifted. There is no ceiling: every machine the operator has is usable, and the protection is the band inside each machine.

1.4 Nothing is hardwired

Omni-Compass carries no table of per-stack special cases. One law (Chapter 30) is written once and runs on every muscle through one plug (Chapter 42). The gains differ from muscle to muscle only through the muscle's declared physics: its response time, its decision period and its cover. Where a rule was found not to work, it was removed, not switched off and left in the code: the engine files are frozen and fingerprinted, and `verify.py` fails if any of them changes. A reader who finds a behaviour in a result can find the exact lines that produced it, and will find no second path.

The rule has a practical consequence for anyone comparing Omni-Compass with a tuned controller. A tuned controller carries, somewhere, a number that someone chose for one stack: a cool-down of five minutes, a target of 70%, a step of two replicas. Each of those numbers is a bet that the stack will behave tomorrow as it did when the number was chosen, and each is one more place where a reader has to ask whether the result was the law or the tuning. Omni-Compass has a handful of such numbers, the centre of the band, the 5% cushions and the 2% do-no-harm line, and they are the same on every muscle, written once in the law and declared in every preregistration. Everything else the law needs (how fast the muscle answers, how often it may be moved, how far it may go) is read from the muscle's own declaration in the catalog (`omnicompass/muscles.py`) or from the native controller's own settings at the start of the run, never typed in by hand for a benchmark. When a benchmark needs a line, a cover or a chunk size (the MySQL pool moves in the server's own 128 MB chunks, the Redis ceiling in notches), the number comes from the stack being governed and is written in the preregistration before the first counted run, where a referee can see that it was not chosen after seeing the result.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

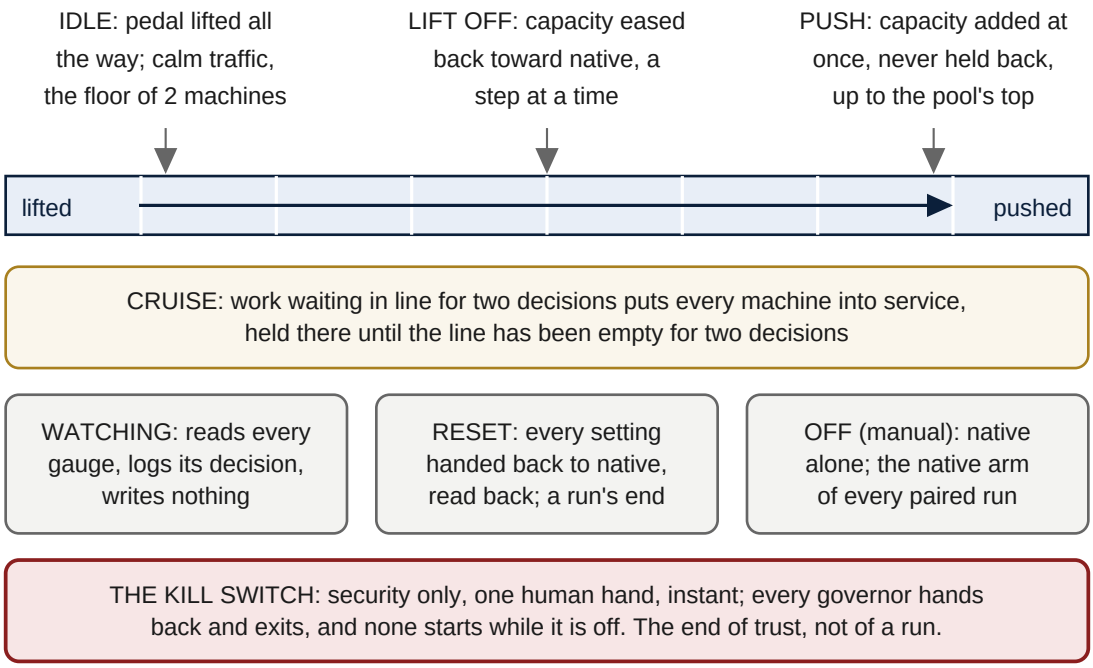

Figure 3. One pedal, no brake. Pushing the pedal adds capacity at once; lifting it eases capacity back toward native a step at a time, never below idle, the floor of two machines. Cruise holds every machine in service while a known queue waits. Watching reads and logs but writes nothing; reset hands every setting back to native and reads it back at the end of a run; off is native alone. The kill switch stands apart from all of these: for security only, in a human hand, instant. After a crash the lease walks every setting back to native on its own.

The second consequence is how the repository changes. A guard or a gain that turned out not to help is not left in the code under a flag, because a flag is a second path that a later reader has to reason about and a later test has to cover. It is removed, the removal is written in the changelog, and the fingerprint moves to the next engine version (Chapter 59), so that no result taken on the old path is ever read against the new one. The three fingerprints that exist, v1, v2 and v3, are the whole history of such changes.

1.5 The word

The law is a **compass**: a band with a cushion at each wall, pushed to its middle by two antagonist forces, smooth, never hammering. The repository uses that word and no other for it. Earlier dated records that used another word are kept word for word, as records are; the current law is `omnicompass/compass_law.py`, `CompassLaw`.

The word was chosen for what the law does, not for decoration. A compass has a needle, a centre it is drawn back to, and a card marked at the edges; it does not slam to a wall and stay there, and it does not chatter when the hand holding it is steady. The law has the same three parts. The **band** is the range the gauge is allowed to travel, from 0 to 1 once the reading is placed on it, with the operator's line at the top. The **cushions** are the last

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

5% at each wall, 10% of the band in all: a reading inside a cushion is already too close to a wall, and the law treats it as such before the line is touched rather than after. The **centre**, 0.5 by default, is where the needle comes to rest, and two forces bring it there: a **pull** proportional to the distance from the centre, gentle near it and harder up the walls, like a spring; and a **push** proportional to the speed at which the reading is moving, meeting whatever is shoving it (a load rising, heat building) with an equal and opposite force and doubling as the friction that stops the needle sloshing past the centre (the gain is chosen for critical damping: it glides to the centre and stops, with no overshoot and no ringing). Past the upper wall the pull goes to its full force at once, and the down side may not act until the reading is back inside the band: the law fails up, never down. The force itself is `A × tanh(raw / A)`: near the centre it behaves as a spring, in proportion to the distance, and far from the centre it bends over and flattens into its maximum `A`, the law's authority, so that no reading, however far out, can make the law ask for more than one full step. That flattening is what "never hammering" means in code: there is no reading that produces a jump, and two readings a decision apart produce two forces a small amount apart. Chapter 30 gives the rules in full and Appendix C the equations; the reader who only needs the picture can keep the needle, the centre and the two cushions in mind and will not be misled by anything later.

1.6 What it sets, muscle by muscle

Every muscle keeps its own control, and Omni-Compass sets what that control already accepts:

Muscle	Its own control (kept)	What Omni-Compass sets
Kubernetes service	the HPA	the HPA's CPU target; replica floors
Kubernetes node pool	Cluster Autoscaler / Karpenter / MachineSet	how many machines stay in service (park and wake)
NVIDIA GPU	the card's firmware (boost, power and thermal limits)	the clock ceiling (up wire) and the power limit (down wire)
CPU	the kernel's frequency governor	the frequency ceiling
Data hall, building	the chiller and air handler loops	the supply-air setpoint; units in service
Battery site	the inverter	the reserve level; the peak ceiling
Robot joint, vehicle axis	the servo loop	speed and effort limits
Process loop, feeder	the PI controller	the setpoint inside its band
Database behind a pooler	PgBouncer's pool, the DBA's fixed setting	the pool size through the pooler's own console
Database's storage engine	MongoDB's WiredTiger cache, the operator's fixed setting	the cache size through the server's own console

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

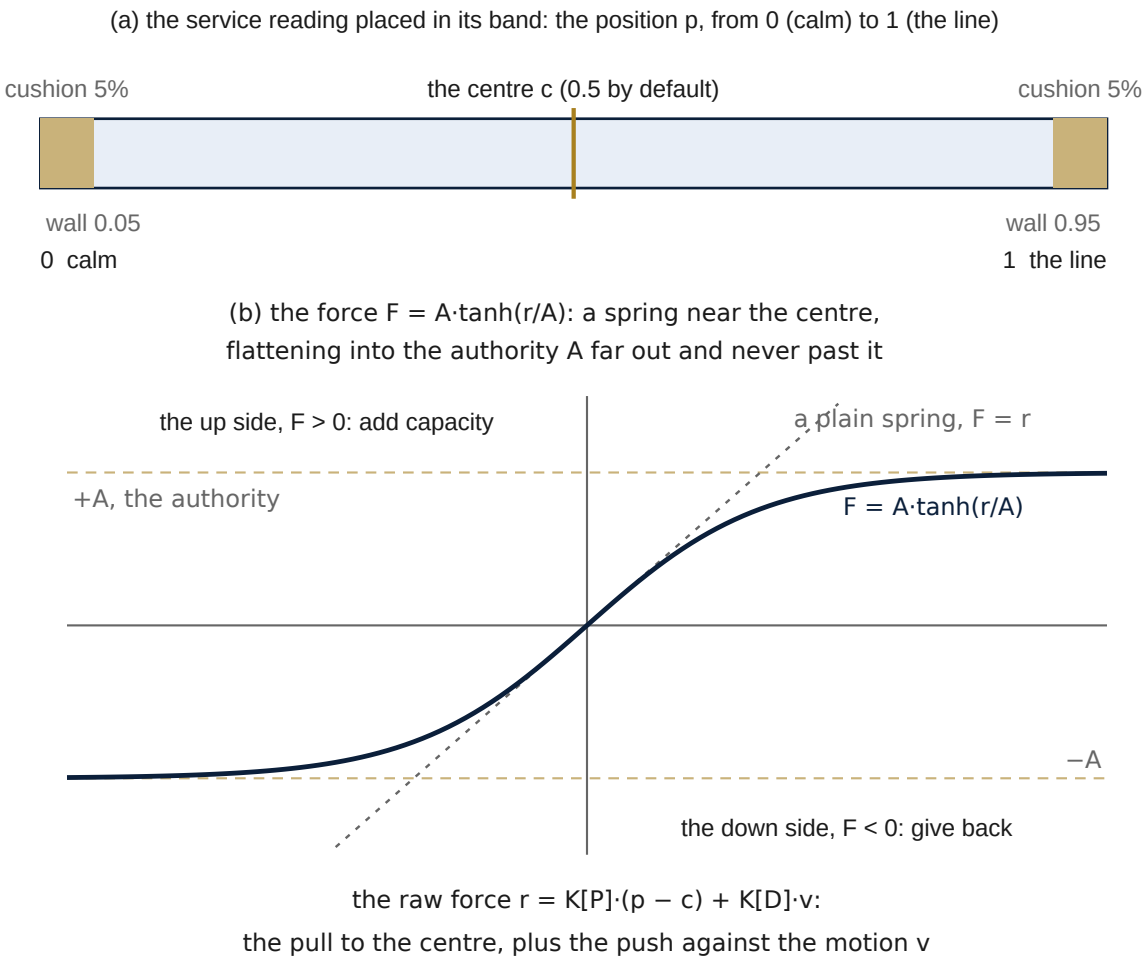

Figure 4. The compass band and the smoothing of the force. (a) The service reading placed in its band as a position p from 0, calm, to 1, the operator's line; the walls at 0.05 and 0.95 leave a cushion of 5% at each edge, and the centre c is where the needle comes to rest (0.5 by default; on a service 0.3 at the max and 0.4 at the tune-down).

(b) The force F = A·tanh(r/A) against the raw force r = K[P]·(p − c) + K[D]·v, the pull toward the centre plus the push against the reading's motion: near the centre a spring, far out a curve that flattens into the authority A and never passes it. Past the upper wall the up side goes to A at once, and the down side may not act until the reading is back inside the band.

Muscle	Its own control (kept)	What Omni-Compass sets
Message broker	the consumer group at the operator's count	how many consumers are in the group
Muscle	**Its own control (kept)**	**What Omni-Compass sets**
Cache	the operator's memory ceiling and eviction rule	the memory ceiling through the cache's own console

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Muscle	Its own control (kept)	What Omni-Compass sets
Substation	the tap changer's own controller	the tap position, one whole tap per move
Drone	the shipped autopilot	the cruise override inside the autopilot's limits

When Omni-Compass stops, every one of those values goes back to what it was before Omni-Compass acted: not to the last value it wrote, but to the value it read once, before its first write.

Where it sits among the systems already in use. The autoscalers, the node provisioners, the GPU and CPU power managers and the commercial optimizers are muscles, or optimizers over a few kinds of muscle; Omni-Compass is the governor on top of them: one law that reads every muscle in a body and writes each one's own knob under the limits they share. Running several of those systems at once does not make one governor, because each still decides on its own reading. The five systems named most often (IBM Turbonomic, Karpenter, NVIDIA's GPU power software, the Energy Aware Runtime, the Cluster Autoscaler with the commercial layers above it), nine open-source pieces with their licenses and where each can be benchmarked, and who owns Omni-Compass and on what terms it is seen, are set out in *The Seat: One Governor over the Muscles* (`docs/THE_SEAT.md`); the distinction between one governor and a collection of tools is stated formally in *The Max, Formally* (`docs/FORMAL_V5.md`, Definition 2 and Proposition 1).

CHAPTER 2

The Referee's Summary: Each Claim, Its Evidence, and What Is Undetermined

Two pages for a CTO, an engineer, a CFO or an attorney who needs the standing of every claim before reading anything else. Every number names its engine and its evidence class: L is live software, the real thing; S is our own models, never proof; P is a physical meter (the cards' own power meters). Every reading is the key's (`docs/HOW_TO_READ_THE_RESULTS.md`), decided by what the gauge is for: from a change of 0.5% or more, GAIN, LOSS or power given, in all three of our runs (A, B and C) or by the mean of the three with the count beyond the noise; STEADY under that floor; the runs disagree where clear runs point opposite ways. Beside every gain stands what it cost. Where no proof exists yet, the word is **undetermined**.

2.1 What it is

A supervisory governor. It sits on top of a system's own controller (Kubernetes' autoscaler, a database's pool, a battery's controller), reads the system, and moves the same settings native moves, inside bounds the system

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

and its operator set. It hands every setting back to native's value when it stops, dies or is switched off (`docs/SAFETY_CASE.md`).

2.2 Each claim and its standing

Every standing below is written from its record by `python3 tools/results_chapter.py`, and `verify.py` fails a push where it differs.

Claim	Standing	Evidence
It sits on top of native and never replaces it	**Shown**	Every live test runs native, and Omni-Compass on top of the same native; the setting is read back at native's value at the end of every arm
It does no harm: never a LOSS against native	**Not shown**: 281 rows read LOSS against its own native on the tables that stand	Each named with its cause and on the next version's list (`docs/LOSS_LEDGER.md`)
More work, faster, on real Kubernetes	**Shown** (L, omni-v26)	All four at once: work inside the response line up 31% to 50% (`results/live/V26_ALL_FOUR.md`); the 95th percentile cut in 9 of 11 Kubernetes tests (`docs/BENEFIT_SHEET.md`)
More work, faster, on databases and caches	**Small** (L, omni-v26)	Redis, the cache's memory ceiling: GAIN, power given, 4.9% LOSS; PostgreSQL, the pooler's pool size: GAIN AND LOSS, 1.8% LOSS; MySQL, the buffer pool's size: GAIN, power given, 12.5% LOSS; MongoDB, the storage engine's cache size: GAIN AND LOSS, 7.1% LOSS; Kafka, the consumer group's size: GAIN, power given, 221.1% GAIN (`docs/BENEFIT_SHEET.md`)
Fewer machines	**Shown in 2 tests** (L, omni-v26)	a service rightsized by CruiseKube applying its own recommendations, Omni-Compass on top, ten pairs, three runs: machines cut 0.3% to 5.3%, machine-hours cut 0.5% to

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Claim	Standing	Evidence
		5.1%; a queue of jobs: machines cut 13% to 28%, machine-hours cut 13% to 28%, machines after the queue cut 22% to 45%
A smaller cloud bill	**Not shown**	Azure, omni-v18, 97 paired repetitions: the bill up 1.2%, inside the noise, and the work not counted (`results/live/AKS_STEADY_100_OMNI_V18.md`); Google and Amazon wired and not yet run
Less energy for the work, on the chip	**GAIN in all three of our runs** on one card (P, omni-v23)	An A10 fully loaded, its own power meter: energy per served request in runs A, B and C GAIN, 1.79%; GAIN, 1.35%; GAIN, 0.78% (`results/gpu/V23_A10_CAP_FULL_ABC.md`); an A100 on omni-v21: STEADY, under the floor (the three runs' mean 0.12%) (`results/gpu/V21_A100_CAP_ABC.md`); energy at the software end is a declared model (S), never scored
More work for the bill on a GPU	**the runs disagree** (P, omni-v23)	The A10's work for each dollar, its three runs up 1.46%, up 0.73%, down 0.69% (`results/TWO_BILLS.md`)
One governor over every muscle and organism	**Modelled** (S)	1,107 muscles in our own models: 530 GAIN, 577 STEADY, 0 LOSS (`results/realms_v5/REALMS_V5.md`); a few dozen knobs on real systems
Its mathematics	**Machine-checked where stated**	24 of 24 theorems proved by SMT and interval arithmetic on the engine as it executes: the compass law, the plug's clip, the verdict, the invariance of E, I and S, the tracking bound inside the basin and the steps to reach

Test (engine)	Gain	What it cost, or read LOSS
A public day of demand (Google 2011) (omni-v26)	mean response cut 49% to 50%; p95 cut 60% to 64%; p99 cut 47% to 54%; time over the line cut 76% to 77%; failed requests cut 8% to 15%; alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) cut 60% to 68%	pod start wait, total (s) up 163% to 173% (LOSS); replicas up 14% to 26% (power given); pods started up 126% to 166% (power given)
A noisy neighbour (omni-v26)	mean response cut 0.4% to 8.0%	p95 up 5% to 11% (LOSS); pod start wait, total (s) up 10% to 23% (LOSS); second app: response time (ms), 95th percentile up 0% to 12% (LOSS); second app: failed requests (%) up 2.0% to 3.3% (LOSS); replicas up 2.0% to 4.0% (power given); pods started up 7% to 18% (power given)
With its add-ons: KEDA's HTTP add-on on the live requests in flight, Omni-Compass on top, ten pairs, three runs (omni-v26)	mean response cut 46% to 49%; p95 cut 41% to 49%; p99 cut 21% to 23%; time over the line cut 64% to 70%; alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) cut 59% to 71%; replicas cut 8% to 14%	parked-worker energy up 1.7% to 1.8% (power given); standby-model energy up 1.7% to 1.8% (power given)
With its add-ons: KEDA on the CPU target and the live requests in flight, Omni-Compass on top, ten pairs, three runs (omni-v26)	mean response cut 28% to 29%; p95 cut 33% to 40%; p99 cut 27% to 34%; time over the line cut 54% to 82%	parked-worker energy up 1.4% to 1.6% (power given); standby-model energy up 1.4% to 1.6% (power given); replicas up 22% to 31% (power given); pods started up 56% to 74% (power given); pod start wait, total (s) up 36% to 112% (LOSS)

The processor given in the add-on tests was idle on machines already running. Where machines are billed by the hour, idle processor put to work costs nothing more unless it raises the machine count, and in these tests the machine count did not rise. Where processor is billed by use, it is a cost, and the table shows it.

2.4 What is undetermined, and what decides it

- **The cloud bill**: the Azure sets on the engine that stands (one at a time); Google once its key is stored whole; Amazon once its account is on the Paid plan.
- **Energy**: a rented machine with the processor's own energy counters and a wall meter.
- **The GPU at scale**: an A100 and an A10 have three-run tables of their own; the eight-card box and the organisms on the card are the next runs, each from one exact commit.
- **Production**: a deployment on a customer's system with their sign-off.
- **Outside review**: no outside party has reviewed, replicated or approved any result here.

2.5 How to check any number yourself

Every table names its runs; `scripts/raw_archive.sh open /run-<id>/` places the run's raw files at the path the table names, with their SHA-256 sums, and the table's own tool rebuilds the table from them (`tools/confirm_abc.py`, `tools/redis_abc.py`, and the like). `python3 tools/omni_version.py --commit <sha>` names the engine a run's commit carries. `python3 verify.py` runs every test and check the repository holds.

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

CHAPTER 3

The Referee's Grades, Category by Category, and the Plan to Raise Each

Our own grading of Omni-Compass in twenty categories, the way a referee or an underwriter would grade a study and a product: the grade given on the morning of 19 October, the grade the evidence supports now, the highest grade the category can reach, and what reaching it takes. These are Dubra Software Inc. / The Omni-Compass LLC's own grades; no outside party has graded, reviewed or approved them. A category with no measurement yet is **Undetermined**, never failed, and is graded once its measurement exists.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

3.1 The chart

#	Category	Morning of 19 Oct	Now	Highest reachable	What reaching it takes
1	Concept	B+	**A−**	A	an outside reading of the concept against its precedents (`docs/RELATED_WORK.md`)
2	Engine code	B−	**B**	A	the next version's fixes (below), coverage of every engine file at 90%, mutation testing of the core; an outside code review for A
3	Engine stability	C−	**C+**	A	one version standing through its whole campaign, every benchmark's three runs, unchanged
4	Mathematics	C+	**A−**	A	CERT-10 proved for every fixture and the bath's amplitude as a number (`docs/ENGINE_PROOFS.md`, section 5)
5	Method	B	**A−**	A	rules timestamped outside our repository before their runs; the pairs the power page asks for
6	Real Kubernetes	B−	**B+**	A	every Kubernetes test's three omni-v11 runs in (seven waiting on their third run), and the cloud's multi-machine cluster
7	Databases and caches	C	**B−**	A−	more pairs a run (`docs/POWER.md`), the max for MySQL, MongoDB and PostgreSQL (archiving), gains where the knob has room
8	Cloud bill	Undetermined	Undetermined	graded on its result	the Azure sets at the cap (running), then Google and Amazon
9	Energy	Undetermined	Undetermined	graded on its result	a physical meter: Kepler and the machine's own meter on a bare-metal machine
10	GPU	Undetermined	Undetermined	graded on its result	the Lambda runs from one exact commit, on the founder's word

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Category	Morning of 19 Oct	Now	Highest reachable	What reaching it takes
11	Modelled muscles	C−	**C−**	B	each plant model calibrated against a measured system, with its error stated
12	Outside simulators	C+	**B−**	A	the swarm's three runs on omni-v12, which carries the reflex fix, with its judged collision row and draws beyond the fixed seeds (below), and BOPTEST beside CityLearn
13	Robustness	B	**B+**	A	the omni-v11 kill and long-run tables are in (no LOSS, every hand-back inside its allowance); next the extended-fault table, a longer after-kill window, then a multi-machine cluster
14	Reproducibility	B	**A**	A+	an outside party rebuilding the tables from the receipts
15	Honesty	A−	**A**	A+	an outside audit of the receipts against the pages
16	Manuals	C+	**B−**	A	an editorial pass of both manuals at referee level, every figure and table against the code
17	Legal	B−	**B**	A	outside counsel's review of the license and the enterprise terms
18	Automation	B+	**A−**	A	the Kubernetes three-run tables built by a bot as the data stores' are; one page of every bot's health
19	Security	C	**B+**	A	the next version without a shell for commands that hold no pipe, signed releases, an outside penetration test
20	Production readiness	Undetermined	Undetermined	graded on its result	a pilot on a customer's own system (`docs/PILOT_PROTOCOL.md`)

3.2 What moved each grade (19 October)

1. **Concept.** Where the idea comes from and what it adds, against supervisory control, reference governors, the Simplex fallback and online experiments (`docs/RELATED_WORK.md`).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

2. **Engine code.** 71% of the engine's 9,685 statements run under the tests (`docs/ENGINE_COVERAGE.md`, measured again on the omni-v15 tree): 82% of the 6,579 in the files that stood before omni-v15, 49% of the 3,106 in the eight runners it took into the fingerprint, which their own benchmarks run whole on GitHub; every proved property checked on thousands of generated cases (`tests/test_engine_properties.py`); every static-scan finding fixed or reviewed (`docs/SECURITY_SCAN.md`). Held at B by a fault found in the swarm's wire, whose code did not do what its own comment says (`docs/LIMITATIONS.md`, section 3), and by the wires outside the fingerprint (`docs/CHANGE_CONTROL.md`).
3. **Engine stability.** The rules and the record of every version, why it changed and how results stay tied to it (`docs/CHANGE_CONTROL.md`); the pace itself is unchanged.
4. **Mathematics.** 24 of 24 theorems proved by machine on the engine as it executes: the compass law, the plug, the verdict, the invariance of E, I and S, the tracking bound inside the basin and the steps to reach it, and the bath's stability (`docs/ENGINE_PROOFS.md`).
5. **Method.** The smallest change every judged row can see (`docs/POWER.md`); every change to every preregistration with its timing (`docs/DEVIATIONS.md`); the chance of a false three-run reading, 3.1×10^{-5} a row (`docs/LIMITATIONS.md`).
6. **Real Kubernetes.** The omni-v11 tables for Goldilocks, both KEDA setups and fixed capacity: 0 LOSS; the omni-v10 LOSS reads STEADY; Omni-Compass's 95th and 99th percentiles below native's in all 90 paired repetitions (`docs/TAIL_LATENCY.md`).
7. **Databases and caches.** Ten omni-v11 tables, 0 LOSS; native as shipped kept apart from the operator's setting (a fault in the front page's grouping found and fixed before any table mixed them).

12. **Outside simulators.** CityLearn 27 GAIN, the power grids 67 GAIN, the robot arms 7 GAIN, the swarm 9 GAIN, 0 LOSS in all four on omni-v11, each rebuilt byte for byte. Held at B− by a fault found in the swarm's wire: on a mission draw outside the preregistered seeds it let drones collide where native did not. The fix held every drone outside the keep-out on all ten cells and draws tried (`results/model_gate/V12_SWARM_REFLEX.md`) and landed in omni-v12; the grade moves when its three runs land.
14. **Reproducibility.** All 23 omni-v11 tables rebuilt from their raw receipts and identical to the byte (`tools/reproduce.py`, weekly in `reproduce.yml`); every package pinned with its hashes, every action by its commit.
15. **Honesty.** The limitations page, the tail-latency page, the runs-disagree rows each explained, every row kept.
16. **Manuals.** Eleven referee chapters bound into the Owner's Manual (the proofs, the coverage, the power, the deviations, the limitations, change control, the security scan, the licenses, related work, the tail latency, these grades).
17. **Legal.** The bill of materials (CycloneDX 1.5, SPDX 2.3) and every dependency's license, with no strong copyleft allowed (`docs/DEPENDENCY_LICENSES.md`).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

18. **Automation.** Every finished run archived by itself; the reproduction and the security scan run by themselves; the conductor stamps each capacity run with its own letter.
19. **Security.** Bandit over 34,000 lines with every high and medium finding fixed or reviewed; 0 known vulnerabilities in the 29 pinned packages; every package hashed; 407 action uses pinned to their commits (`docs/THREAT_MODEL.md`, T8 closed).

3.3 The blueprint

On GitHub already, at no cost. The robustness kill test and long run and the three data stores at the max landed on 19 October (no LOSS in any); the third runs of the seven Kubernetes sets, the extended fault test and the CruiseKube rerun on the corrected recorder are running, and the cost to match runs again from the campaign. Each lands as an omni-v11 table and raises categories 6, 7 and 13.

The next engine version, on the founder's word (`docs/CHANGE_CONTROL.md`: any change to a rule or guard is the next version, and every benchmark runs again on it):

- the swarm's proximity reflex at once, reaching out with the square of the speed (in our own flights: every drone at or outside the keep-out on the four preregistered cells and six draws the wire was never run on, where omni-v11 collided once), with a judged collision row and draws beyond the fixed seeds in its preregistration;
- every wire that holds a governor's rules taken into the fingerprint;
- a command with no pipe run without a shell;
- the Redis harness's brain in its own process, as a deployment runs it;
- the Kubernetes governor counting a worker an add-on marks while it serves, and keeping its clock under load.

What a buyer will ask for that is not here yet (the founder's question of 19 October, answered from the repository):

- *Proof*: a physical meter (every energy figure is a declared model; the GPU on Lambda or a metered machine closes it); a cloud bill on the engine that stands (Azure running, Google's key and Amazon's plan pending); native at its best (the cost to match, native tuned harder by its operator beside Omni-Compass on top, last run on 3 October on an engine long gone, runs again on omni-v11 from the campaign); an outside party's rerun; a real multi-machine cluster (kind puts every node on one runner); days to weeks on a real workload; each rule's share of the gain read on the live cluster, not only in our models.
- *Gauges*: measured joules and grams of carbon; the cost of 1,000 requests; the 99.9th percentile (the probes are too sparse for it); the operator's own terms (availability, error budget, burn rate) beside the alert minutes; each muscle's headroom to its own limit; the governor's own calls to the cluster's API. Now read for every omni-v11 Kubernetes table (`results/STEERING.md`): moves, reversals and distance travelled an hour, the share of decisions with the compass in its band and at the line, the time from the line back into the band, and errors an hour.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- *The operator's screen*: in. The gauges feed and a Grafana screen (`tools/omni_exporter.py`, `deploy/grafana/omni-compass.json`, read-only); ten alert rules (`deploy/prometheus/omni-compass-rules.yaml`); and the control panel (`tools/omni_control.py`): an authenticated API with an OpenAPI document and a console with the buttons (mode autopilot, watch or off; the dial, max or tune-down; reset to native; the kill switch for every governor on the machine; the two-person arm), roles on every button and every press logged. It writes no setting itself: every change goes through the governor's own hand-back and a restart with the new arguments, so the engine does not change for it (`docs/OBSERVABILITY.md`). Still to build: a row per muscle with its own hand-back and watch-only buttons (the engine that stands takes its mode for the whole governor, so that comes with the next version, through the model gate); the live native-against-Omni panel; a one-line install (a Helm chart); two governors with leader election.

Mathematics. CERT-10 for every fixture by entry bounds taken cell by cell instead of over the whole box; the bath's amplitude from a discrete Lyapunov function per cell.

Tests. Every engine file to 90% coverage; mutation testing of the core, the compass law and the verdict.

Outside parties (the founder decides each): a referee's review, a penetration test, counsel's review of the license, and an independent replication from a fork.

The undetermined categories. The Azure sets at the cap are running; a bare-metal machine with Kepler and its own meter measures energy; the Lambda runs measure the GPU from one exact commit; a pilot measures production.

CHAPTER 4

Related Work: Where the Idea Comes From, and What It Adds

`docs/COMPARISON.md` sets Omni-Compass beside the systems that run data centres today (the Kubernetes autoscalers, Borg, Twine, Turbonomic, the power managers). This page sets it beside the published ideas it is built from, so a referee can see which parts are known technique and which part is the claim. Each idea is named with the work that stated it.

4.1 A supervisory layer over a controller that already works

Omni-Compass never replaces the native controller. It moves the same settings native moves, inside bounds the system and its operator set, and native keeps running underneath.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Advanced process control over regulatory control.** In process industries the fast loops (PID controllers on valves and pumps) are left in place and a supervisory layer, usually model predictive control, moves their setpoints (S. J. Qin and T. A. Badgwell, "A survey of industrial model predictive control technology", *Control Engineering Practice* 11(7), 2003). Omni-Compass has the same layering: the native autoscaler, pool or firmware is the regulatory loop; Omni-Compass is the supervisory layer.
- **Reference and command governors.** Such a scheme modifies the reference given to a loop that is already stable, so that constraints hold, and leaves the loop itself alone (E. Garone, S. Di Cairano and I. Kolmanovsky, "Reference and command governors for systems with constraints: a survey on theory and applications", *Automatica* 75, 2017). This is the closest formal relative of Omni-Compass: it moves a setting, inside a cover, on top of native.

What differs. Reference governors are usually designed from a model of the closed loop and prove constraint satisfaction from it. Omni-Compass carries no model of the system it governs: it reads the system, steps, and lets each step stand only if a paired trial on the system itself shows it did no harm (section 4.3). Its own law is proved bounded, monotone and Lipschitz (`docs/ENGINE_PROOFS.md`, C1 to C8), but the safety of a step in a given system rests on the trial and the cover, not on a model of that system.

4.2 A fallback that is always there

- **The Simplex architecture.** A high-performance controller runs beside a simple, verified safety controller, and a decision module hands control to the safety controller whenever the system leaves a recoverable region (L. Sha, "Using simplicity to control complexity", *IEEE Software* 18(4), 2001).

Omni-Compass's fallback is native itself. Every setting is snapshotted before the first write and handed back at the end, on the kill switch (instantly) and, if Omni-Compass dies, by the lease's walk back (`docs/SAFETY_CASE.md`, `omnicompass/master.py`). The fallback is not a second controller written for the purpose; it is the controller the system was already trusted with.

4.3 Changing a live system one tested step at a time

- **Online controlled experiments.** A change is shown to a share of live traffic and kept only if a paired comparison says it helped (R. Kohavi, R. Longbotham, D. Sommerfield and R. M. Henne, "Controlled experiments on the web: survey and practical guide", *Data Mining and Knowledge Discovery* 18, 2009).
- **Safe exploration and shielding.** A learning controller may explore only inside a set a shield has proved safe (M. Alshiekh et al., "Safe reinforcement learning via shielding", AAAI 2018); control barrier functions keep a system inside a safe set by construction (A. D. Ames et al., "Control barrier functions: theory and applications", European Control Conference 2019).

Omni-Compass's verdict (`omnicompass/verdict.py`) is a controlled experiment run on the governed system itself, one step at a time: a step is allowed only when its paired trial does not read LOSS against either the setting before it or native, its cost stays within 2% of the cost first measured at native, and steps cannot add up past that (proved: V1 to V3). The cover plays the shield's part: no write leaves it (proved: P1 to P3).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

4.4 Feedback control of computing systems

- **Control theory applied to software.** Queue lengths, utilisations and response times are controlled with classical feedback, analysed with the tools of control engineering (J. L. Hellerstein, Y. Diao, S. Parekh and D. M. Tilbury, *Feedback Control of Computing Systems*, Wiley-IEEE Press, 2004).
- **Production systems.** Google's Autopilot sets containers' limits and replica counts from their history (K. Rzadca et al., "Autopilot: workload autoscaling at Google", EuroSys 2020); Borg schedules the work (A. Verma et al., "Large-scale cluster management at Google with Borg", EuroSys 2015); Heracles uses feedback to share machines between latency-critical and batch work (D. Lo et al., "Heracles: improving resource efficiency at scale", ISCA 2015); power is provisioned and capped across whole facilities (X. Fan, W.-D. Weber and L. A. Barroso, "Power provisioning for a warehouse-sized computer", ISCA 2007; Q. Wu et al., "Dynamo: Facebook's data center-wide power management system", ISCA 2016).

Omni-Compass's law is a bounded, smooth one (the compass law, a tanh of a proportional-derivative reading inside a band with 5% cushions), not a linear PI loop, and the same law with the same verdict is applied to every knob it governs, from a pod's CPU limit to a battery's charge rate.

4.5 What Omni-Compass claims, against this background

Each part has a precedent: the supervisory layer (section 4.1), native as the fallback (section 4.2), the tested step (section 4.3), feedback on computing systems (section 4.4). The claim is the combination, applied the same way to every muscle of a stack:

- one bounded law and one verdict for every knob, on top of each knob's own native controller;
- a step allowed only when the system itself shows it did no harm against native, with the cost bounded stepwise;
- every setting handed back to native's value at the end, on the switch, or on the governor's death;
- results read only by a preregistered three-run rule, every row shown.

Whether the combination does what it claims is a question for the measurements, not for this page: `docs/REFEREE_SUMMARY.md` gives each claim's standing, and `docs/LIMITATIONS.md` what the measurements cannot yet say.

CHAPTER 5

The Seat: One Governor over the Muscles

This page states where Omni-Compass sits among the systems that already run computers, power and machines, what each of those systems is, who owns what, and what is still to be shown. Every statement about another system is read from that system's own publication or repository, on the date given; every statement

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

about Omni-Compass is read from this repository's code and results. Where a statement is wrong or out of date, it is corrected from the maker's own publication.

5.1 The claim, in one sentence

Omni-Compass is a **supervisory governor**: one control law that reads every muscle in a body at once and writes each muscle's own knob, inside the envelope its native controller already allows, under the limits the muscles share, while every native controller keeps running underneath, unchanged. It is never standalone and never a replacement for the is").

What makes it one governor and not a collection of tools is stated formally in `docs/FORMAL_V5.md` (Definition 2 and Proposition 1): the knob it writes on one muscle depends on what every other muscle is doing, through the lines they share (a battery site's grid connection, a room's cooling). A collection of separate tools cannot have that property, however many run at once: each decides on its own reading and writes only its own knob.

5.2 Muscles and governors

A **muscle** is a controller of one kind of knob on one kind of system: how many machines, how many replicas, a power limit, a frequency, a temperature setpoint, a cache size. A **governor** decides, for the whole body at once, what each muscle may do. The systems in common use are muscles, or optimizers over a few kinds of muscle; Omni-Compass sits on top of them and calls them.

5.2.1 The five systems named most often

System	Maker	Source	What it controls (its maker's description)	Kind	Omni-Compass with it
IBM Turbonomic	IBM	closed, commercial	resource actions across layers: sizing, placement and scaling of workloads and hosts	an optimizer over several kinds of muscle, not one control law	on top of the muscles it drives, or compared on the customer's own system in paired runs; it cannot be run here

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

System	Maker	Source	What it controls (its maker's description)	Kind	Omni-Compass with it
Karpenter	AWS; its core is a Kubernetes SIG Autoscaling project (`kubernetes-sigs/karpenter`)	open source (Apache-2.0)	provisions and removes nodes for pending pods	node-provisioning muscle	on top: Omni-Compass decides when nodes are needed ahead of demand; Karpenter provisions them (register row 68, on a cloud)
NVIDIA's GPU power-management software (power profiles and the dynamic power tools above the driver)	NVIDIA	closed (user-space software on top of the driver; the Linux kernel and its NVIDIA modules are a separate layer)	power limits and power profiles on NVIDIA GPUs	power-limit muscle	on top: Omni-Compass writes the card's clock ceiling and power limit through the driver's own tool (`nvidia-smi -lgc`, `-pl`; `omni_controller/gpu_compass.py`), inside the envelope the card allows; the receipt is the chip-level energy run (section 5.5)
Energy Aware Runtime (EAR)	Barcelona Supercomputing Center	open source (EPL-2.0, `github.com/eas4dc/EAR`)	CPU frequency selection per application and node, energy	energy muscle with its own optimizer at node and job	on top, on bare metal with access to the CPU's power

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

System	Maker	Source	What it controls (its maker's description)	Kind	Omni-Compass with it
			accounting, and a global energy manager for supercomputers	level	registers (register row 87)
Cluster Autoscaler, with commercial layers such as ScaleOps and Cast AI	the Kubernetes project; the vendors	Cluster Autoscaler open source (Apache-2.0); the commercial layers closed	adds nodes when pods cannot be placed, removes them when unneeded; the commercial layers sell optimization on top	node muscle, and optimizers above it	on top of the Cluster Autoscaler (register row 68); the commercial layers are compared on a customer's system, as Turbonomic

Run all five at once and there are still five systems, each reading its own gauges through its own interface and writing its own knobs. Nothing among them makes one decision for the whole body under the limits the muscles share. That is the seat Omni-Compass is written for.

5.2.2 Open-source pieces that can be benchmarked with Omni-Compass on top

Read from each repository on 12 October 2026 (its README, its license file and its last commit). The license is the file in the repository, not a description of it.

Project	Repository	What it is, in its own words	License found	Last commit	Kind	Where it can run	Register
Kepler	`sustainable-computing-io/kepler`	"a Prometheus exporter that measures energy consumption metrics at the container, pod,	Apache-2.0	2026-10-12	a meter, not a controller	a machine with the processor's power registers (RAPL), through the meter kit (`docs/METAL_KI`	row 79

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Project	Repository	What it is, in its own words	License found	Last commit	Kind	Where it can run	Register
		and node level in Kubernetes clusters"				`T.md`); on GitHub's virtual machines Kepler 0.10 and later run only a stand-in development meter	
Goldilocks	`FairwindsOps/goldilocks`	"a utility that can help you identify a starting point for resource requests and limits" (built on the Vertical Pod Autoscaler's recommender)	Apache-2.0	2026-09-18	a recommendation tool over a muscle (VPA)	GitHub's machines (kind)	row 80
CruiseKube	`truefoundry/cruisekube`	"an intelligent Kubernetes resource optimization controller that automatically monitors, analyzes, and applies resource recommendations"	**Business Source License** (source-available, not open source)	2026-08-06	a rightsizing muscle	GitHub's machines (kind), for evaluation under its license	row 81

All patents, copyrights and trademarks filed in the USA.

Project	Repository	What it is, in its own words	License found	Last commit	Kind	Where it can run	Register
		Balancing Energy Efficiency, Thermal Control and Performance" (HPDC '25): a learned model choosing GPU power caps	permission)			grant use	
NVIDIA Power Manager	`NVIDIA/nvidia-power-manager`	"Nvidia power management app."	Apache-2.0	2026-07-13	platform power muscle (NVIDIA server platforms)	NVIDIA server hardware	row 86
Energy Aware Runtime	`eas4dc/EAR`	"an energy management framework for super computers"	EPL-2.0	2026-09-28	energy muscle and optimizer (HPC)	bare metal with the CPU's power registers, under a batch scheduler	row 87

Already benchmarked or registered: the Kubernetes HPA (every Kubernetes set), KEDA and its HTTP add-on (done, three runs), Karpenter, the Cluster Autoscaler and the Vertical Pod Autoscaler (register row 68).

None of these projects is described by its makers as one law deciding for the whole body. That is a statement about their public descriptions on the date above, not a proof that nothing else exists anywhere.

5.3 How a benchmark with each of them is built

The same way as every benchmark here: the project, installed as its makers ship it, is the native; Omni-Compass on top of it is the other arm; both arms see the same work; the rules are written before the counted runs, frozen on one tuning case and run three times (A, B, C); every row is reported, losses included (`docs/HOW_TO_READ_THE_RESULTS.md`). A meter (Kepler) is not an arm: it reads both arms the same way, so its numbers sit beside the arms' own gauges.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Order (one or two at a time): Goldilocks with the Vertical Pod Autoscaler, and Kepler as the shared meter, on GitHub's machines first; CruiseKube next under its license's evaluation terms; the GPU and platform power pieces in the Lambda kit; EAR and the processor power managers on bare metal when a machine with power registers is rented.

Built so far: **Goldilocks** (register row 80; `scripts/kind_addons_goldilocks.sh`, workflow `kind-goldilocks`, `docs/GOLDILOCKS_PREREGISTRATION.md`), run three times on the card version (`results/live/V5_GOLDILOCKS.md`): the service faster in all three of our runs, machines the same, 1.9% to 2.6% more energy on the declared model, every row shown. **CruiseKube** (register row 81; `scripts/kind_addons_cruisekube.sh`, workflow `kind-cruisekube`, `docs/CRUISEKUBE_PREREGISTRATION.md`), beside KEDA's HTTP add-on, since CruiseKube leaves alone a service whose autoscaler scales on CPU: a trial run proves the wiring and records its chart's SHA-256 for the pin, then three counted runs.

As muscles in the organisms (the founder's order of 12 October: "expand my organisms"): each of the nine is also a muscle of the catalog (`realms/catalog_v5.csv`, ids 2172 to 2181), modelled on the plant its knob turns and placed in the spine family that knob belongs to, so each is in all four realms, the four stacked and the whole tower: Kepler's energy reading driving a pool's target, Climatik's inference power cap, EAR's CPU frequency policy and global energy budget, CruiseKube's and Goldilocks's request rightsizing, the Kubernetes Power Manager's core profiles, PEAKS's power-aware placement, the learned GPU power cap and NVIDIA's platform power budget. A model of a knob is not the project itself (class S); the project's own benchmark is the live test of it.

5.4 Who owns Omni-Compass, and on what terms it is seen

- **The copyright in Omni-Compass belongs to Dubra Software Inc. / The Omni-Compass LLC.** Contributions are accepted only on the terms of `.github/CONTRIBUTING.md`, which assign their rights to Dubra Software Inc. / The Omni-Compass LLC.
- **The source is visible under the Omni-Compass Evaluation License (`LICENSE`): evaluation and Simulation use only.** It is not an open-source license. Any commercial use, commercialization, monetization, production use, redistribution or hosted service requires a signed, paid Omni-Compass Enterprise License. Seeing the source grants no right beyond the Evaluation License.
- **Two licenses from one owner.** The owner of a copyright may grant it under more than one license at once (an evaluation license to everyone, a paid enterprise license to a customer), may set the terms of each new version, and may assign the copyright. Copies already received keep the terms they were received under.
- **All patents, copyrights and trademarks covering the Omni-Compass engine, its mathematics and its software have been filed in the United States by Dubra Software Inc. / The Omni-Compass LLC.**
- This section states how the repository is licensed; the license texts (`LICENSE`, `NOTICE`, `DISCLOSURES.md`) govern.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

5.5 What is shown, and what is still to be shown

What is shown, and by which kind of evidence, is set out receipt by receipt in `docs/THE_RECEIPTS.md`. In one line: on real software (class L), Omni-Compass on top of native has given faster service and more work inside the response line on the same machines, and memory back on databases at the same service, with no row LOSS in all three runs on the real stacks; on our own models (class S) no muscle alone is behind native.

The decisive receipt still to be produced is a physical one (class P): the chip's own energy meter on a real GPU, native against Omni-Compass on top, on the same clock and with the same membership as the Kubernetes runs. Every earlier card result ran on a controller since replaced and is obsolete. The run is the founder's, on rented cards, at one exact commit, after the CPU side is done (`docs/GPU_RUN_GUIDE.md`, `docs/GPU_PREREGISTRATION.md`). Until it lands, no energy saving on real machines is claimed. The seat is claimed by design and by the receipts on this page; it is held when the receipts cover it.

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

CHAPTER 6

The Unified Circle Principle

Omni-Compass begins with one idea: a system that is closed, bounded and pulled toward a center cannot run away, and everything it does is a return. I call this the closed circle. This chapter states the principle as I hold it, in its mathematical form, and then says plainly which parts of it the software uses and which parts belong to the wider theory the software grew out of.

6.1 The statement

```
dX/dt = G(X),        X(0) in Omega, a subset of R^n
G(X) . n(X) <= 0     on the boundary of Omega
grad L(X) . G(X) <= 0
=>  lim (t -> infinity) X(t) in M*, a subset of F
```

Read line by line:

1. **dX/dt = G(X).** The state X moves according to one law G. There is no outside hand: every change comes from the law and the state it is in.
2. **X(0) in Omega.** The state starts inside the admissible region Omega: the set of states that are physically and operationally allowed.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

3. **G(X) . n(X) <= 0 on the boundary.** At the wall of Omega, the flow never points outward (n is the outward normal). Nothing that starts inside can cross out. In control theory this is the Nagumo condition: Omega is forward invariant.
4. **grad L(X) . G(X) <= 0.** There is a function L, the energy of the compass, that never increases along the motion. This is a Lyapunov condition.
5. **=> X(t) settles in M*.** Together, an invariant container and a non-increasing energy force every path into the set M* where the energy stops falling: the bottom of the compass.

The power of the statement is that it does not depend on the particular disturbance. Every input up to the size the container is built for has the same answer before it is asked: the state stays inside and returns. That is what I mean when I say that a closed circle holds the answer to every question that can be put to it.

6.2 Closure, admissibility, boundedness

The theory sets five requirements on any law that claims to close the circle:

Requirement	Meaning	In the engine
Finite deviation	the distance from the admissible state has a ceiling, abs(E) <= E[max]	the deviation state E drains faster than it can fill
Finite curvature	the landscape the state moves on has no infinite slopes or pits	the drive is bounded by tanh; the authority is clipped
Global conservation	what flows in is matched by what flows out	the drain and the bath's friction match the drive
Recurrence	a disturbed state returns arbitrarily close to where it was	convergence to the target pole at rate K[P]
One law	every subsystem obeys the same law, no special cases	one engine, one compass, every muscle

6.3 The closed circle tested

The canonical evolution law has four parts: deviation is damped nonlinearly and coupled to alignment and to the basin; alignment relaxes toward unity and responds to deviation; the basin's curvature evolves with internal structure; damping absorbs excess growth and redistributes energy. Bounded random noise is permitted; divergence is not. A cycle is identified when the system returns arbitrarily close to a prior state within a bounded tolerance under noise. The state advances stepwise under a stable numerical integrator with boundedness checks. Under parameter sweeps the test is always the same three checks: no divergence, bounded, recurring.

All patents, copyrights and trademarks filed in the USA.

6.4 Symmetry and conservation in the closed circle

Every conservation law is the shadow of a symmetry (Noether). The closed circle carries four:

Symmetry	Conserved	In Omni-Compass
Temporal (the law does not change with time)	energy	the same law governs every decision; the receipt compares like with like
Spatial (the law does not depend on where)	momentum	the same law governs every muscle in every realm
Rotational	angular momentum	the compass is symmetric about its center; the engine is symmetric between its poles
Internal alignment	alignment invariance	the alignment state is pulled to its pole whichever pole it is

Around them sit the boundary conditions of the circle: maximum deviation (the boundary limit), topological closure (bounded wholeness), nonlinear dynamics (complex interactions), resonant reversal (feedback return), energy-momentum conservation, and cross-scale invariance (scale-independent patterns).

6.5 Scale invariance

The theory claims that one bounded nonlinear action has the same form at every scale: cosmological (curvature geometry, compression and expansion, thermodynamic cycling), galactic (rotation curves, mass-energy distribution), stellar (gravitational compression, fusion equilibrium, radiative transport), atomic (electron displacement, orbital coherence, radiative damping) and quantum (localized deviation wells, bounded oscillation, finite amplitude). The universal criteria for such a law are that it operates at every scale and preserves bounded deviation, finite curvature and recurrence. The state vector carries the same meaning at every scale: E the deviation magnitude, U the coherence or flow alignment, S the structural curvature or basin geometry, B the redistribution or damping.

6.6 The lineage of unification

Each step in the history of physics unified two things that had been separate: geometry formalized structure; motion was unified across earth and sky; astronomy revealed recurrence; fields replaced action at a distance; curvature unified gravity, though singularities remained; symmetry came to govern the quantum realm. The closed circle is offered as the next step: unity without divergence, a single bounded law with no singularity and no runaway.

6.7 What is tested and what is theory

The software uses the engineering core of this principle, and every part of that core is checked:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- The six-state engine, its bounded control command held through the integration step, and the convergence of its alignment state to its pole are proved (`docs/TRACKING_THEOREM.md`) and tested against a C++ twin.
- The invariance and boundedness of each engine state were checked state by state (Chapter "Closing the Circle").
- The compass law pulls every muscle's service reading to the middle of its band under a bounded, smooth force, and its behavior is measured in simulation and on real software.

The wider claims - one law across every physical scale, the cosmological and quantum readings, the candidate unified action - are the theory from which Omni-Compass was built. They are stated here so that the engineer understands where the design comes from. They are not claims that the software has measured, and no result in this book depends on them.

CHAPTER 7

The Four-Piece Engine

The engine is built in four pieces, stacked like the stages of a press, each feeding the next:

Piece	Name	What it establishes
1	Foundational Engine	the base laws, the states and the boundaries: a closed, bounded, nonlinear adaptive engine with a four-state dynamical structure (misalignment, alignment recovery, coherence potential, path interaction), bounded convergence and persistence with decay, intrinsic feedback and stabilization, and an empirical validation framework for recovery
2	Geometric Response	geometric alignment and response dynamics: a geometric coherence field, a unified potential governing geometric deformation, and the propagation mechanism of that response
3	Coherence Evolution	coherence through response and adaptation: the coherence-response envelope, the system response field, and the coupling of coherence state with response propagation

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Piece	Name	What it establishes
4	Unified Master Field Law	one coherent field structure: it integrates pieces 1-3 into one closed dynamical structure with a unified potential governing all subsystems, bidirectional propagation between engine state, geometry and response, bounded convergence across the whole system, and no external authority: all evolution emerges from internal coupling

The four pieces compress every domain through one center core. The compression process has four stages: the domains unordered; compression in progress; coherence achieved; return to equilibrium. The result has four properties: coherent, bounded, admissible, stable - one law, one return, one cycle.

The 24 domains. The theory gathers 24 domains into four quadrants around that core:

Quadrant	Domains
1. Foundational structures	Newtonian gravity; Maxwell electromagnetism; Einstein relativity; Schrodinger quantum mechanics; Shannon information theory; Dirac quantum field theory
2. Dynamics and symmetries	Noether symmetry laws; Hamiltonian dynamics; Lagrangian mechanics; thermodynamics; topology; differential geometry
3. Coherence evolution	gauge field theory; fluid dynamics; field theory; discrete mathematics; solid-state physics; plasma physics
4. Complex systems and integration	astrophysics; consciousness and information integration; biological systems and self-organization; universal mathematical structure; systems theory and complex adaptive systems; the unified Omni-Compass domain (the unified admissible state)

In the software, the four pieces appear as the engine's state equations (piece 1: deviation, alignment, memory and basin), the basin potential and its flow (piece 2), the bath that absorbs and redistributes (piece 3), and the one governor that couples every muscle to one law with no outside authority (piece 4).

CHAPTER 8

The Compass

The Omni-Compass rose is the whole mechanism drawn as one picture.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The ring. Twenty-four letters, the complete Greek alphabet from Alpha to Omega: the complete set, nothing missing, one letter for each domain. On a ring the end runs back into the beginning: after the last letter the ring returns to Alpha. That is the closed circle: identity, return, cycle.

The four points. Four letters are lifted out of alphabetical order and set on the four points of the rose:

Point	Letter	Mark	Meaning in the engine
North	Alpha, the first	+	the positive pole of the alignment's double well, U = +1
South	Omega, the last	-	the negative pole, U = -1
East	Beta	>	the drive coming in (the beta terms that fill the deviation)
West	Gamma	<	the coupling that carries energy out to the bath, where friction absorbs it

The north-south line is polarity; the east-west line is flow in against flow out. A system stays inside its circle exactly when what flows out can always match what flows in.

The inner marks.

Mark	Meaning	In the mechanism
+ and -	the two polarities	the two poles of the double well
> and <	push out, pull in	the antagonist pair: the up force and the down force
the double arrow	exchange both ways	the two-way wire: read in, write out
the up-tack	the ceiling	the cover: nothing goes past the top
approximately-equal	the wave, the tolerance	the band and its cushion: hold near the center
the star	the guiding star	the target the needle points to

The center. The spiral at the middle is the attractor: every path winds inward to one point.

Opposite letters. Across the center, zeta faces xi: both are the engineer's symbol for the damping ratio, and a damping ratio of one is the critical glide to the center with no overshoot. Lambda faces psi: the eigenvalue and the wave function of the eigenvalue equation.

All patents, copyrights and trademarks filed in the USA.

CHAPTER 9

Basins, Polarity and the Dual-Basin Engine

9.1 Geometric funneling and basin formation

A basin forms in three stages. While the driving tension T is low, curvature is weak and there is no dominant basin: flows spread outward. As T increases, curvature concentrates and a positive feedback loop begins. Then a stable geometric funnel forms: self-reinforcing curvature, finite depth, bounded deviation, with the boundary abs(E) <= E[max] respected. Structure emerges from fluctuation through curvature concentration and feedback.

In the engine, the basin state S rolls down its potential Phi(S) to a stable bottom; in the compass, every muscle's service reading is pulled into the bottom of its own funnel.

9.2 Polarity

Two like charges repel without anyone pushing them: the force comes from the shape of the field. A wall built of like polarity at the edge of a band pushes the state back harder the closer it comes (as one over the distance squared), and two such walls cancel at the center, where the state comes to rest. This is the boundary condition of the closed circle written as a force: the field itself points inward at the wall.

The repulsion does not create energy: the field stores what it took to bring the charges together. What is gained in the computer is that the force is computed rather than spent: the brain computes it at no physical cost, and the machine's energy is saved because its knob no longer fights itself.

A symmetric pair of repelling walls was tested on the modelled GPU card. It raised work per energy but also raised the time spent past the service line, because the lower wall pushed capacity away when the card was calm. It was removed. The upper wall alone remains a candidate.

9.3 The dual-basin engine

The dual-basin engine is a recursive transform with five stages:

1. **Compression.** Two outer basins of positive polarity draw matter and energy inward in a spiral; rotation organizes the flow; compression increases toward the center.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

2. **Saturation.** At the center, two cores of negative polarity meet back to back; the basin structure S reaches its critical value and the curvature reaches its maximum.
3. **Transition (ignition).** Where the cores touch, the transition operator T(X) = sigma(S - S[c]) T(X) activates: compression halts and redistribution begins.
4. **Redistribution.** Two axial jets carry the excess out along the axis, with opposite helicity to the inflow.
5. **Reset and recurrence.** The domain relaxes and the cycle repeats.

The core mathematics is a bounded flow: dX/dt = G(X, t) with abs(G(X)) <= C[G], a curvature envelope K(X) <= K[max], and a redistribution term that activates only at saturation. The state X = (E, U, S, B) stays in its admissible domain, whose horizon boundary is forward invariant (the Nagumo condition again).

For an engineer, the transform reads: pull toward the center (compression); a wall where the muscle saturates; and, when one muscle saturates, move the excess to its siblings rather than hammering it (redistribution). The first two are built into the compass. Redistribution across muscles is designed and not yet built; it is on the roadmap.

CHAPTER 10

The Reflex Rule: One Body, One Brain

A body does not decide in advance how much force a muscle will need. It sends a signal, the muscle moves, the nerves report what the movement did, and only then does the brain choose the next signal. Nothing in that loop is a forecast. The decision is made on the reaction, after the reaction, and from the reaction. The founder's order of 10 October 2026 puts the whole of it in one sentence: what the brain sends to a muscle has to coincide with what the muscle sends to itself and where it is at. This chapter is the theory of that sentence, and the reason it is the whole mechanism rather than one more rule beside the others.

10.1 The reflex, not the forecast

The compass of the earlier chapters is a force: where a reading sits in its band, how hard the two opposing forces push it back toward the middle, and how smoothly. A force alone does not say when it may become a new setting. A governor that turns every urge straight into a move is a governor that guesses, and a guess made on a machine that is already working is a guess paid for by that machine. The reflex rule closes the gap: a new setting is earned by a trial on the muscle itself, and the trial is read from the muscle's own reaction. The urge proposes; the reaction disposes.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

10.2 A trial runs to its end

The rule that taught this was broken in a measured run. On 10 October the message broker's consumer group was given a spend trial: one more consumer, then measure. The extra consumer drained the waiting messages so fast that the service went calm at once, and the harness of that day ended the trial the moment the calm arrived, before the measurement it existed to take. Every spend was abandoned by the success it caused. A trial that can be ended by the calm it creates can never prove that it was worth it. Hence the first rule: a trial runs to its full measurement and is never ended by the calm it causes; only the wall, a service reaching its line, or the engine's own time limit ends it early. In the one repetition of that day in which the brain allowed the third consumer early, the whole of the earlier gain came back at a fraction of the spend: the slowest five percent of messages from 2,450 ms to 57 ms, the queue from 3,375 waiting messages to 253, the work done inside the line up 17%, with 2.5 consumers on average where the earlier law had spent six to eight. The gain is real and cheap; what was missing was a fair trial of it.

10.3 No forcing: the need and the urge

A spend is tried only when the muscle's own reading says there is something to buy: messages waiting, a cache missing, clients queued at a pool. A give-back is tried only when the whole body is calm. The compass force is the urge, smooth and bounded; the muscle's own condition is the need. The brain never moves a muscle because it wants to. It moves it because the muscle has shown that a move can pay, and then only by trial.

10.4 One body, one brain, one tick

A muscle judged alone can be read GAIN by pushing its neighbour away from its own: a cache that takes memory from the database beside it, a consumer that takes processor time from the service it feeds. So the brain reads the whole body first, every muscle's state, every service's speed and work, the host's processor, memory and energy where a meter exists, and judges the body's cost: the Omni index's own arithmetic over all the work, all the speed, all the machines and all the resources. On top of the body's total stands a guard for every part. A step is refused if any one service read LOSS beyond its cushion, even when the total improved. Pushing one thing to a LOSS to move another toward its own is refused by rule, not by luck.

That guard is do no harm in its strictest form, and it is the form the engine that stands keeps. The founder's words of 19 October 2026 give do no harm its meaning (`DISCLOSURES.md`, section 3): the real goal is the organism, to strengthen it and keep it healthy, working at the best state its own muscles can carry, turning whatever is fed into it into the most and best output it can make. Harm is the organism turning out less than native makes it turn out, or made less healthy: a muscle past its own limit, a service over its own line, anything made to fail. Within that, the muscles are one body: where one muscle's strength cannot be used without straining another, the brain offsets and engages them together, and it may use one muscle less, or leave it native, so that another can carry more, whenever the whole organism comes out ahead and every muscle stays healthy. The guard above refuses every such trade, the good with the bad; the next engine version replaces it

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

with that judgment of the whole organism and of every muscle's health, through the model gate first, and every result is run again on it.

10.5 One trial at a time, nothing permanent, the wall belongs to the body

If two muscles move together, the brain cannot tell which one caused what it feels. Inside a body, one new trial runs at a time, granted to the muscle asking loudest whose own condition holds; every other muscle keeps acting inside what it has already proven, so nothing is frozen and only new trials wait their turn. Every allowed step is tried again on the recheck and pulled back when it stops paying, and a muscle at native is asked again whenever its signal returns: native is where the brain stands when it has not yet been shown a reason, never a verdict. And if any service reaches its line, the trial stops, that step is undone, and every force in the body lifts off. The wall is the body's, not the muscle's.

10.6 Why this is the closed circle again

The Unified Circle Principle says that a system closed on itself, bounded, and pulled toward its center cannot run away: everything it does is a return. The reflex rule is that principle carried into time. The loop is closed through the system's own reaction; every excursion is bounded by the trial's limits, the cover and the wall; and every allowance is pulled back to native unless the body keeps proving it. The compass holds each reading in the middle of its band. The reflex holds each decision in the middle of what has been shown.

10.7 What it means for the evidence

Omni v3, the engine on main, already tries a slow knob on the muscle itself before it moves it, and the live harnesses carry the same verdict around every live knob. Omni v4 is the engine written to make the rule hold on every wire by construction: one body that every muscle's wire passes through, the trial's rules inside the verdict, and no wire that can write around them. Because that changes the engine, v4 carries its own fingerprint, the package version follows it, and every result in this book is run again on it. No result is read across engines.

PART TWO

The Mathematics

Eight equations, one control law, and the proofs, audits and declarations that hold them fixed.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

CHAPTER 11

The Canonical Declaration

Every report the engine has ever produced opens with the same declaration. It is the birth certificate of the mechanism: what the engine is, which equations it runs, what every symbol means, which parameters it samples, how a run is born, conveyed and certified, and what the engine is allowed to say about itself. This chapter sets it down in full so that anyone who reads the rest of this book can always come back to the source.

11.1 The identity of the engine

The Omni-Compass Unified Governing Convergence Control Core Engine. One canonical eight-line mathematical core, called Piece I, integrated by fourth-order Runge-Kutta (RK4) and exercised by Monte Carlo. Around that core sit the benchmark suites: the public enterprise manager mechanism benchmark, the one-stack-normalized global megastack, fragmented stack governance over matched scenarios, and the enterprise evidence suite covering cause, fail-safe, scale, muscle, security and economics. All of them run on bare metal, on premises, private, public, hybrid and edge alike, because the core does not care where it runs.

11.2 The equation form (authoritative, eight lines)

```
(1) dE/dt   = -α_E E + β_int(t) + β_ext(t) + v_eff
(2) dU/dt   = μ U(1 - U²) - (dE/dt)/E_max - λ_U U + u,      |u| ≤ U_AU
    ↪ THORITY
(3) dI_U/dt = 1 - U - σ₁ E - δ S - λ_I I_U
(4) v_eff   = χ(t) c · tanh(λ₀ + λ₁(U - U_t) + λ₂ S),       χ(t) = cos
    ↪ (ω_B t / 2)

(5) Φ(S)    = ½ α_s S² + ¼ β_s S³ - δ S
(6) dS/dt   = F_state(S) = -∂Φ(S)/∂S = δ - α_s S - ¾ β_s S²
(7) B'' + (ω_B / Q_B) B' + ω_B² B = γ_c δ S                  [continu
    ↪ ous]
(8) R_B[n] = D²_h B[n] + (ω_B / Q_B) D⁻_h B[n] + ω_B² B[n] - γ_c δ S[n
    ↪ ] = 0    [discrete audit]
```

Line (1) is the error, the energy of misalignment: it decays at its own rate, it is pushed by forces from inside and outside, and it is pushed by the effective velocity of the system. Line (2) is coherence, the alignment index: it lives in a double well with two homes at +1 and -1, it is pulled down by any rise in error, it leaks, and it is the one line the governor touches, through the control u, which is never allowed beyond its authority. Line (3) is the information channel that keeps the record of how far coherence has been from home. Line (4) is the effective velocity, saturated so that it can never exceed the limiting speed c, and multiplied by the spinor

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

phase. Lines (5) and (6) are the potential of the coherence state and the flow it creates, downhill. Line (7) is the bath, the field that every real system sits in, driven by the state. Line (8) is the bath written on the grid the computer actually steps on: it is an audit of the numbers, not a second bath.

11.3 The control law

```
σ        = nearest_signed_basin(U₀)
u_m      = sat(-f_U(x_m, t_m) + K_P (σ - U_m), ± U_AUTHORITY)
x_(m+1)  = RK4_h(x_m; u_m),   u_m held across all four RK4 stages
```

The nearest signed basin is declared at Step 0, before the first microstep. The control cancels the natural drift of coherence and adds a proportional pull to the declared home, then it is clipped at its authority. It is held fixed through the four stages of each RK4 step. There is no post-step overwrite of the state and no projection onto the basin. Whatever the engine reaches, it reaches by the flow of its own equations.

11.4 The symbol chart

Symbol	Meaning
E	Error, the misalignment energy
U	Coherence, the alignment index
I[U]	Information, the internal-coherence channel
S	Coherence state potential
B	Bath field
B'	Bath field time derivative
α	Feedback rate
β[int] (t)	Internal forcing function
β[ext] (t)	External forcing function
k	Coherence logistic damping gain
σ_1	Coupling of error into the information channel
δ	Linear coherence coupling parameter
λ_0	Saturation bias
λ_1	Saturation gain
λ_2	S-state coupling gain
U_t	Target coherence state
c	Limiting velocity

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Symbol	Meaning
E[max]	Per-trajectory error-rate normalization scale
α_S	S-potential quadratic coefficient
β_S	S-potential cubic coefficient
Φ(S)	Potential field function
F[state] (S)	Canonical S-state flow
ω[B]	Bath frequency
Q[B]	Bath quality factor
γ[c]	Bath coupling gain

11.5 The coupling architecture of Piece I

The closed feedback core is E, U and S: error drives coherence, coherence and the state drive the velocity, the velocity drives error. The information channel I[U] and the bath B with its derivative are driven response channels: they listen to the core and record it, and the core does not depend on them. γ_1 is reserved for compatibility and is inactive in the Piece I derivatives. The bath law uses ω_B^2 B, so ω[B] carries the units of angular frequency. Line (7) advances B and B' continuously by RK4. Line (8) evaluates the discrete residual with D^2_h B[n] = (B[n+1] - 2B[n] + B[n-1]) / h^2 and D^-_h B[n] = (B[n] - B[n-1]) / h.

11.6 The spinor closure

The spinor extension introduces the phase θ(t) = ω[B] t and multiplies line (4) by χ(θ) = cos(θ/2). At 0 degrees the factor is +1, at 360 degrees it is -1, and at 720 degrees it is +1 again. A full turn of the bath reverses the sign of the velocity; only two full turns bring it home. The standard 20-step run evaluates the part of the phase it reaches, and a dedicated evidence test checks the 0, 360 and 720 degree periodicity on its own.

11.7 The signed basins

The canonical Monte Carlo sampler draws the starting coherence U(0) symmetrically on [-1, +1]. The nearest signed basin at Step 0 is declared the target before the first microstep. That keeps the eight-line equation exactly as written while making every governed run exercise capture into both +1 and -1. A separate dual-basin suite throws runs across from one basin to the other under disturbance and watches them recover.

11.8 Birth, conveyance and certification

Step 0 is the sampled state before integration. Step 1 is the first completed macro step. A run has at most 20 macro steps of 10 micro steps each, at a time step of 0.1. A step is in basin when U lies within 0.10 of +1 or -1.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Born in basin.** A run that starts inside a basin at Step 0 is born in basin for life. Step 0 counts as the first observation of its streak. It is confirmed conveyed after Steps 0 to 4 stay in the same basin. It is never called self-tuned, and it stays under the same regulation for all 20 macro steps.
- **Self-tuning.** A run that starts outside both basins is self-tuning applied from Step 1. The same nearest-basin law is active on every trajectory, born or not, over the whole 200-microstep horizon. The category never switches the regulation off.
- **CONVEY-5.** Five consecutive same-basin observations. The first is the conveyance entry step, the fifth is the confirmation step. The latest streak may start at Step 16 and confirm on Step 20.
- **CERT-10.** Ten consecutive same-basin observations. The latest streak may start at Step 11 and complete on Step 20. The code asserts both bounds before it runs and checks every emitted row against them.

Conveyance is an event, not an ending. No run may be both born in basin and self-tuned. Stability is judged on the history, not on one snapshot.

11.9 The Monte Carlo declaration

Setting	Value
Initial U distribution	Uniform on [-1, +1], symmetric
Monte Carlo runs	500
Macro steps per run	20
Micro steps per macro step	10
Integration time step	0.1
Basin centers	+1 and -1
Basin tolerance	0.10
Stability window	5
Conveyance cutoff step	20

The full horizon is always executed. A run is classified as a failure if it crosses the divergence threshold at any recorded state, or if it exhausts the horizon without CONVEY-5.

11.10 The parameter sets

Group	Parameter	Value or range
Core	α	4.2
Core	β[int]	0.0 to 1.0
Core	β[ext]	0.0 to 1.0
Core	E[max]	1.0 to 10.0, sampled once per trajectory

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Group	Parameter	Value or range
Core	k	1.7
Information and coupling	σ_1	0.38
Information and coupling	δ	0.01 to 1.0
Information and coupling	γ_1	1.35, reserved, inactive in the derivatives
Information and coupling	$\gamma[c]$	1.0
Saturation and phase	c	0.5 to 5.0
Saturation and phase	λ_0	-2.0 to 2.0
Saturation and phase	λ_1	0.1 to 3.0
Saturation and phase	λ_2	0.0 to 2.0
Saturation and phase	U_t	0.5
Saturation and phase	$\chi(t)$	$\cos(\omega[B]\, t / 2)$ when the spinor closure is on
S-state potential	α_s	0.05 to 0.25
S-state potential	β_s	0.05 to 0.25
Bath	$\omega[B]$	0.1 to 5.0
Bath	Q[B]	0.5 to 10.0
Noise and drift	D	0.0
Noise and drift	μ	0.0

11.11 The mechanism-bound reporting doctrine

Every table, grid, chart, scorecard, classification and conclusion the engine emits must be computed from what it actually executed: the trajectory rows, the recorded state histories of E, U, I[U], S, B and B', the sampled parameters, the RK4 derivative evaluations, the basin entry and dwell histories, the line (8) residuals, the solver comparisons, the ablations, the disturbance and stress runs, the compute benchmark event records, and the enterprise benchmark ledgers.

No decorative grade, inferred score, hand-assigned quality category or presentation-only number is allowed to stand as an engine result. Prose may point to the exact source and the edge of the claim. It may not manufacture evidence, put a grade where a measurement belongs, or present a grid the mechanism never ran as though it had. That doctrine runs through every page of this book.

11.12 Availability and the rights boundary

Time is of the essence. Omni-Compass is available from Dubra Software Inc. / The Omni-Compass LLC for controlled technical evaluation, research collaboration, pilot integration, strategic engagement and separately licensed commercial deployment. The same rights boundary applies at every level of use: inspection, local execution, simulation, research, benchmarking, observe-only, shadow mode, supervised control, bounded autopilot, hybrid control, direct-to-muscle control, production, embedding, hosted service, productization, monetization, redistribution and derivative work.

Public access does not make Omni-Compass open source. Commercial use of any kind requires a separately executed written license. The instrument is a license, not a sale and not a transfer of ownership. For planning only, the introductory benchmark is 10% of independently verified and contractually accepted value captured; the base and the amount are specific to each company, the terms are expected to rise as validation and adoption grow, and only a signed agreement creates any obligation.

CHAPTER 12

The Engine: Eight Equations and One Control Law

The engine (`omnicompass/core.py`, frozen and fingerprinted) carries a six-part state x = (E, U, I[U], S, B, Ḃ):

State	Meaning	Physical picture
E	deviation: how far the system is from where it should be	a tank that fills with stress and drains on its own
U	alignment, between the two poles -1 and +1	a ball in a double well: two stable poles, a hill between them
I[U]	memory of misalignment	an integrator that remembers and slowly forgets
S	basin structure	a ball rolling to the bottom of its landscape
B, Ḃ	the bath	a spring with friction that absorbs and settles energy

The eight equations (Appendix C gives them in full):

1. dE/dt = −α[E] E + β[int] + β[ext] + v[eff]

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

2. $dU/dt = \mu\, U\,(1 - U^2) - (dE/dt)/E[max] - \lambda[U]\, U + u$, with $|u| \le 25$
3. $dI[U]/dt = (1 - U) - \sigma_1\, E - \delta\, S - \lambda[I]\, I[U]$
4. $v[eff] = \cos(\omega[B]\, t / 2)\, c \tanh(\lambda_0 + \lambda_1\,(U - 0.5) + \lambda_2\, S)$
5. $\Phi(S) = \alpha_s\, S^2/2 + \beta_s\, S^3/4 - \delta\, S$
6. $dS/dt = -d\Phi/dS$
7. $d^2B/dt^2 = \gamma[c]\, \delta\, S - (\omega[B]/Q[B])\, dB/dt - \omega[B]^2\, B$
8. R[B]: a finite-difference audit of (7), never fed back

The control law. $u = clip(-f[U](x, t) + K[P]\,(\sigma - U), -25, +25)$, where f[U] is the drift of U with the command at zero, σ is the target pole and K[P] = 12. The first term cancels whatever is shoving U (the push); the second pulls U to its pole, harder the farther it is (the pull). The command is held unchanged through every stage of the fourth-order Runge-Kutta step and U is never rewritten afterwards. Inside the authority limit, U converges to its pole at rate K[P]; this is proved (`docs/TRACKING_THEOREM.md`).

12.1 What each equation does, in words

The six numbers describe the whole system the way a physician's six vital signs describe a patient, and each equation says how one of them moves.

- **Equation 1, the deviation tank.** *E* is how hard the system is being driven: queues, overload, power, heat. It drains on its own at a fixed rate (α[E] = 3.487) and is filled by two pressures, internal (queue and overload, β[int]) and external (power, heat, network, staleness, security, β[ext]), plus a drive term v[eff] that is bounded by a hyperbolic tangent. However extreme the observation, the engine's response rate is capped at c = 1. This is the saturation, the "speed limit" that no input can exceed.
- **Equation 2, the alignment.** *U* is how healthy and settled the system is, and it lives in a double well: two stable poles at +1 (healthy) and −1 (failed) with an unstable ridge at 0. A rising deviation pushes *U* out of the healthy well; the bounded command *u* pulls it back. The cubic term $\mu\, U\,(1 - U^2)$ is what makes the walls of the well push back harder the farther *U* strays.
- **Equation 3, the memory.** *I[U]* grows while *U* is below its pole, is reduced by deviation and stress already being dealt with, and leaks at λ[I] = 0.719. It is the engine's memory of unrelieved pressure: a system that has been stressed for an hour is not the same as one stressed for a second, and this integrator is what knows the difference.
- **Equation 4, the drive.** The bounded drive v[eff] mixes the alignment and the stress through a tanh, with a slow cosine of the bath's frequency on top, so the drive breathes rather than pushes constantly.
- **Equations 5 and 6, the stress.** *S* rolls downhill in a cubic potential to its stable root. It is the slowest restoring force: structural stress from heat, power, network, security and staleness that builds and relaxes over minutes rather than seconds.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

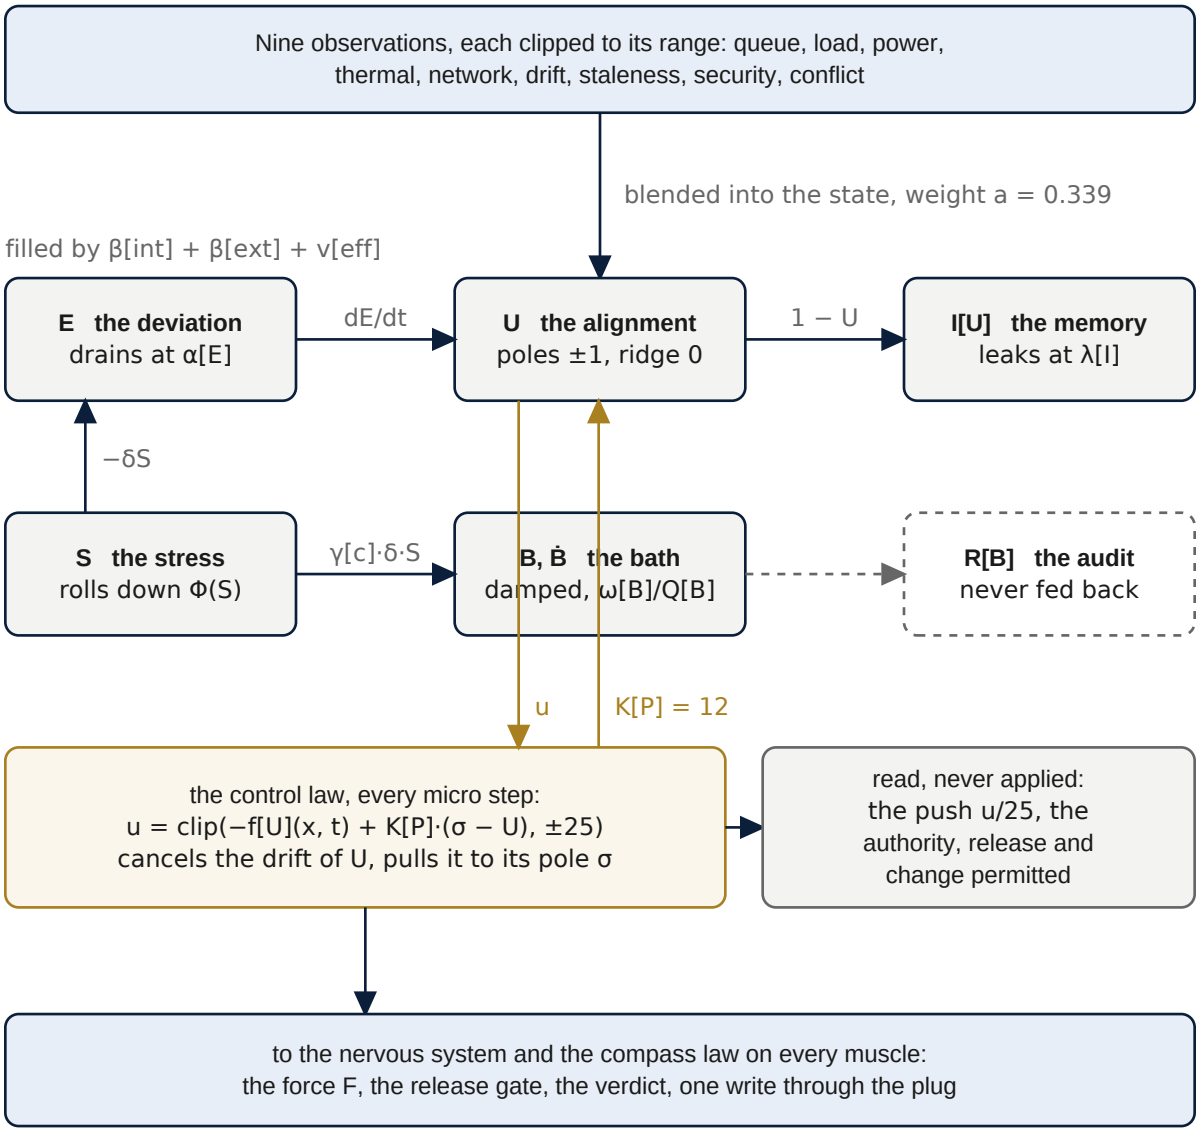

Figure 5. The engine's six states and the control law. Nine clipped observations are blended into the state x = (E, U, I[U], S, B, Ḃ) with weight 0.339 and the state moves one macro step. The deviation E drains at α[E] and is filled by the two pressures and the bounded drive v[eff]; its rate of change pushes the alignment U, a double well with poles at ±1; the need 1 − U accumulates in the memory I[U], which leaks at λ[I]; the stress S rolls down its cubic potential Φ(S), drives the bath B through γ[c]·δ·S and enters E and I[U] through −δS; the audit R[B] re-checks the bath and is never fed back.

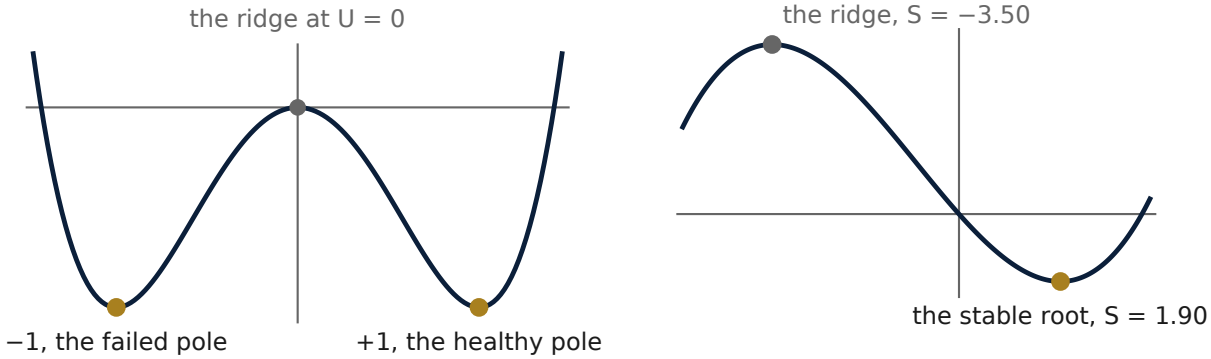
The control law u cancels the drift of U and pulls it to its pole at rate K[P] = 12; it is read, never applied to a knob: the push u/25, the authority and the release permission go to the nervous system and the compass law.



- **Equation 7, the bath.** A damped harmonic oscillator (natural frequency ω[B] = 1, quality Q[B] = 2.5) driven by stress. It turns stress into a smooth, lagged tide, and it is the only second-order element in the engine; its friction is what settles the whole.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Equation 8, the audit.** The bath equation is re-checked numerically every step with a finite difference, and the check is recorded and never fed back: an instrument on the engine, not a part of it.

(a) the alignment U, a double well:
$V(U) = \mu(U^4/4 - U^2/2)$

(b) the stress S, a cubic potential:
$\Phi(S) = \alpha_s S^2/2 + \beta_s S^3/4 - \delta S$
(α_s 0.12, β_s 0.10, δ 0.5: the engine's defaults)

$dU/dt = \mu U(1 - U^2) + \ldots$
the ball rolls to the nearer pole

$dS/dt = -d\Phi/dS$: S rolls to the stable root;
the landscape is open below the ridge

Figure 6. The two landscapes inside the engine. (a) The alignment U lives in a double well, $V(U) = \mu(U^4/4 - U^2/2)$, with stable poles at +1 (healthy) and −1 (failed) and an unstable ridge at 0; the drift $\mu U(1 - U^2)$ rolls the ball to the nearer pole. (b) The stress S rolls down the cubic potential $\Phi(S) = \alpha_s S^2/2 + \beta_s S^3/4 - \delta S$; with the engine's default parameters the stable root is at S = 1.90 and the ridge at S = −3.50, below which the landscape is open (its closure is given in the chapter Closing the Circle in the Engine).

Integration is classical fourth-order Runge-Kutta, ten micro-steps of 0.01 per macro step, and the C++ twin matches the Python to 3.6×10^{-15} on 500 reference trajectories (Chapter 86).

12.2 From telemetry to state, and from state to action

Each decision, the telemetry is normalised to nine observations: queue, load, power, thermal, network, drift, staleness, security and conflict. An observed state is computed from them by fixed weights (`omnicompass/adapter.py`, `observe_vector`), the engine's state is blended toward it with weight 0.339, and the state is then evolved by one macro step of the equations. From the state, the governor evaluates the control's push, u(x)/25, which is a number between −1 and +1 that says how hard the engine is pulling toward health; a target utilisation that falls as the memory and the deviation rise; whether a release (giving something back) is permitted at all, which is only while the push reports convergence and the band and dwell allow; and whether change is permitted, which requires *U* above its gate and no security block. All of this is written to the audit every decision (`docs/MECHANISM_OF_ACTION.md`, sections 3 to 6, and `python`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

`tools/mechanism.py`, which reproduces the measured numbers in `results/MECHANISM_OF_ACTION.json`).

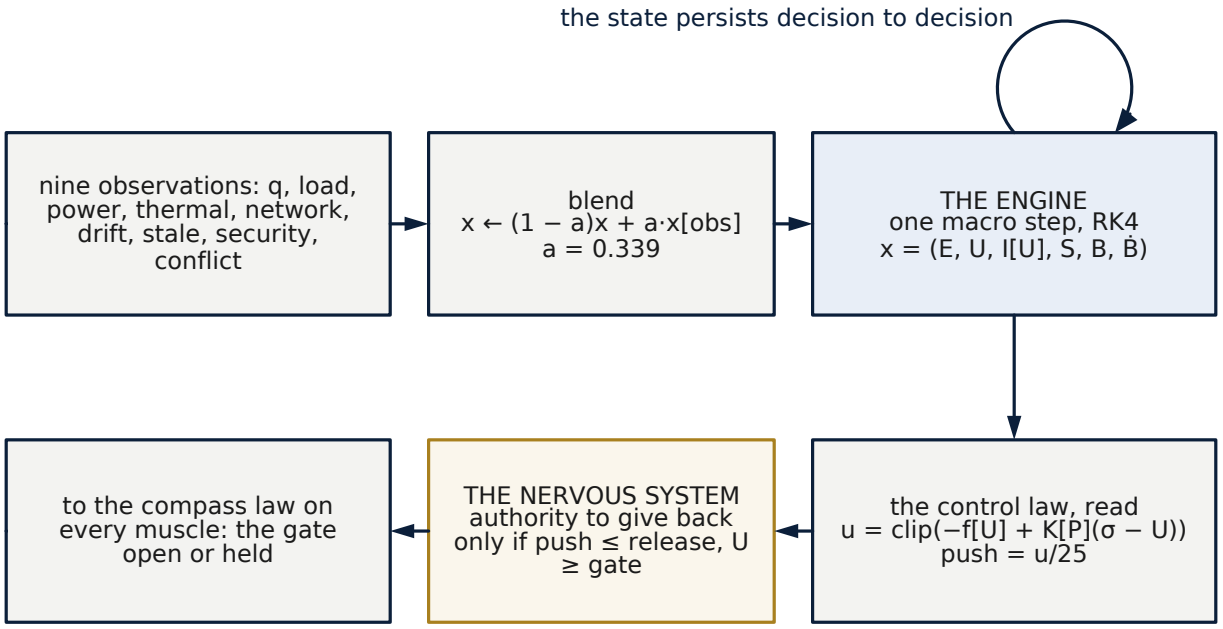


Figure 7. Block diagram: from the observations through the engine to the authority. The nine clipped observations are blended into the state x = (E, U, I[U], S, B, Ḃ) with weight a = 0.339; the engine moves one macro step (RK4) and its state persists from decision to decision; the control law u = clip(−f[U] + K[P](σ − U)) is read, never applied to a knob, and its push u/25 goes to the nervous system, which grants the authority to give back only while push ≤ release and U ≥ gate. What leaves the chain is the gate's state, open or held, to the compass law on every muscle.

The nine observations are worth naming in plain words, because every later number is a weighted sum of them (`omnicompass/adapter.py`, `observe_vector` and `assimilate`). **Queue** is the work waiting as a share of the work being served; **load** is utilisation against the stack's own target; **power** and **thermal** are the electrical and heat stress against their limits; **network** is the same for the wire; **drift** is how far the levers stand from where native had them, so that a governor that has pushed far from the operator's settings reads as more stressed than one that has not; **staleness** is the age of the readings, which rises when a sense goes quiet; **security** is the hold flag; and **conflict** counts other hands seen on the levers. Each is clipped to a declared range before it is used, so no single runaway reading can swamp the others. The stress the engine assimilates leans most on the queue (a weight of 0.25) and on load above 85% of target (0.18), then power, heat, network and drift in that order, with conflict and staleness last; the utilisation it blends toward falls with the queue first (0.27) and with power and heat next. The weights are fixed numbers in the frozen engine, the same on every stack, and a reader who wants to know why a decision read the body as stressed can recompute the sum from the audit line, which records all nine observations. What the weights encode is a judgement made once: that

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

work waiting is the first sign of a body in trouble, that a lever far from native is itself a mild stress, and that a reading one cannot trust is a reason for caution rather than for action.

12.3 Where the engine sits, and where the compass law sits

A reader meeting the engine and then the compass law (Chapter 30) may ask which of the two moves the knob. The answer, in the live controllers, is this: the **compass law** sets each knob, the **verdict** narrows where the law may go, and the **engine** grants the authority, feeds the release gate and the nervous system, and is audited every decision (`omni_controller/controller.py`, its docstring). The engine is the organism's physiology: how stressed it is, how long it has been, whether it is settling. The compass law is the hand on each lever. The engine's own control law u is evaluated, not applied to a knob directly: it is the push the nervous system reads to decide whether giving anything back is permitted now. This separation is why the engine could be frozen with its proofs untouched while the compass law was written as its own, separately tested law, and why `verify.py` seals both.

One decision, followed through, shows the order. The controller wakes on its period and reads its senses: the service gauge (a response time, a statement latency, a consumer lag), the resource gauge (machines, connections, memory) and the knob's current value read back from the device. The **engine** takes the normalised observations, blends its state toward them and evolves one macro step; from the state it reports whether the body is converging, what authority the organ has earned and whether a release is permitted at all (section 12.2). The **compass law** then reads the service gauge as a position in its band and computes the force (Chapter 30): positive, and the direction rule asks for capacity in proportion; negative, and it asks for one notch back, but only if the engine's release gate is open, the resource is demonstrably idle and the dwell has passed. The **verdict** stands over the slow knobs: a knob the paired trial has not cleared at the 2% line is not moved at all and stays native. What survives all three is one write to the **plug**, read back from the device, and one line in the **audit** that records the senses read, the engine's state and push, the force, the gate's reasons and the value sent and taken. In the kill test's first repetition (section 32.1) this produced 114 such lines and 42 writes: every decision that wrote nothing is in the record with the reason the gate held, which is the point of writing all of it down.

12.4 The tune: one tuned engine, the tuning bench, and the rule that chooses the factory tune

Everything above is one engine. What it delivers on a given organism depends on how it is tuned, as a car's engine delivers differently as its mixture, intake, exhaust, firing and pistons are set. The benchmarks read one tune, the factory tune; the live benchmark engine page is a bench on which any tune can be turned and watched live. This section states what a tune is and how the factory tune is chosen, so that the claim the benchmarks make is exact (`docs/THE_TUNE.md` carries the same with the first search's preregistration).

The tune is a point $\theta = (\theta_1, \ldots, \theta_k)$ of the knob space $\Theta = \Theta_1 \times \cdots \times \Theta_k$: for the Kubernetes governor, among others, the beat $P \in [5, 120]$ s, the compass's balance point $c \in (0, 1)$, the dial, the verdict's allowance and

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

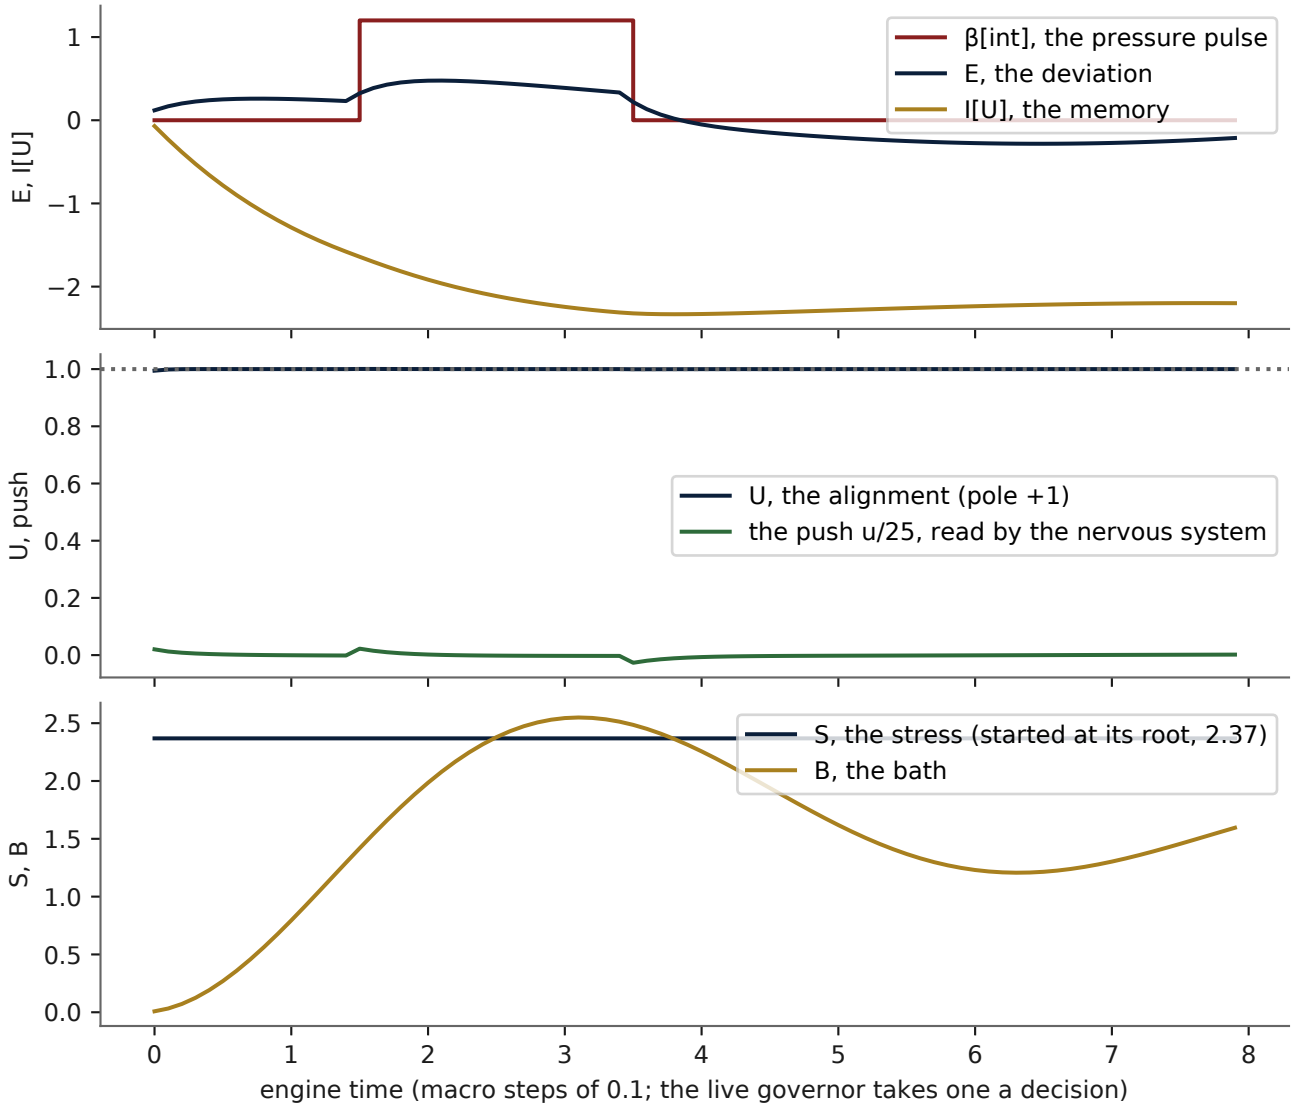

Figure 8. Modelled trace: the engine's six states answering a pressure pulse (class S: omnicompass/core.py with the control law on, the stack's parameters, started at the stress root). An internal pressure β[int] = 1.2 is applied from macro step 15 to 35: the deviation E rises and drains, the memory I[U] accumulates the need, the alignment U holds at its pole while the push u/25 is read by the nervous system, and the bath B fills from the stress S.

trial length, the cruise wait, each muscle's card. The factory tune is one point, θ*, fingerprinted with the engine. On an organism S under a load L, each seed s ∈ Ω (Ω the set of seeds) gives native's gauges $g^{o}(s) \in \mathbb{R}^{n}$ and Omni-Compass on top of native at tune θ gives g(θ, s). The one key reads each gauge j from the paired differences $d_j(\theta; s) = g_j(\theta, s) - g^{o}_j(s)$: their mean $\bar{d}_j$, their 95% interval $[\ell_j, u_j]$ by Student's t on

Ω	− 1 degrees of freedom, the word $R_j(\theta)$ (STEADY when $\ell_j \le 0 \le u_j$; else GAIN on the side the gauge's aim serves; else LOSS for a

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

time waited, missed or failed and for work, power given for a resource) and the size $r_j(\theta) = \dot{d}_j / \bar{g}^{o}_j$.

Admissible tunes harm no gauge against native: $A = \{ \theta \in \Theta : R_j(\theta) \neq \text{LOSS}$ for every j, every muscle within its own limit $\}$, and in a cloud $R[\text{bill}](\theta) \neq$ power given as well. This is do no harm in the strict form the engine that stands keeps.

The order on A follows what a tune is for: the max serves the organism's output and gives power to buy it. With J_s the service gauges (time waited, missed or failed, work; in a cloud the bill too),

$$F(\theta) = \left(\left|\{ j \in J_s : R_j(\theta) = \text{GAIN} \}\right| , \Sigma \{ |r_j(\theta)| : j \in J_s, R_j(\theta) = \text{GAIN} \} \right),$$

compared lexicographically; energy and machines spent are shown beside as power given and never minimized for their own sake.

Dominance. $\theta' \succ \theta$ when, read against θ seed by seed, no gauge of J_s reads LOSS (in a cloud, no rise in the bill) and one at least reads GAIN. **The factory tune stands** on a searched set $\Theta_s \subseteq \Theta$ when $\theta^* \in A$ and no $\theta \in \Theta_s \cap A$ dominates it.

Three consequences bound the claim. It is non-dominance among the tunes searched, read in the models and benchmarks that read them, never a global optimum over the continuous Θ. It trades nothing between service gauges, so it never buys one with another (the trade judged on the whole organism is the next version's work, section 3 of `DISCLOSURES.md`). And it is selected on development seeds and read again on untouched ones: a tune that dominates θ^* is a candidate, read in the model gate on seeds the search never saw against the engine that stands, landed as the next version only where it reads no LOSS there, then run three times on every benchmark. The rule is code, `tools/tune_study.py`, held by `tests/test_tune_study.py`; the first search (the beat from 15 to 120 s and the balance point, in the kind benchmark's setting and the cloud's, seeds 101 to 108) is read on its own page in `results/model_gate/` when it finishes.

The live tuning bench, as the page carries it (`docs/engine/OMNI_COMPASS_LIVE_ENGINE.html`; read monitor by monitor in the Live Benchmark Engine Manual). The page opens on the bottom line (one light and one number against native for each way to run it and for each route), then the monitor wall and the main control panel. Native is orange everywhere, Omni-Compass on native blue, Omni-Compass direct violet; red is never a side, only the alarm. Every monitor carries its light and its word: green and round, **GAINING** (low in its band with room to climb, or a GAIN); yellow, a yield diamond, **STEADY** (STEADY, inside 0.5%, or heading for its line and watched); red, a stop-sign octagon, blinking, **REDLINING** (over its line, or a LOSS: the alarm); dark, **AWAITING** (the run that fills it has not landed; never green). The main control panel holds the kill switch, the arm (Omni-Compass on native or direct), the heartbeat's seven buttons, $\Delta \in \{10, 15, 20, 30, 60, 90, 120\}$ s, a sweep that runs every beat on the page's own model for three model days each and reads each day against native by the key, **Try the candidate** (the sweep's best beat, the one with the most work for Omni-Compass on native and no LOSS, as a candidate profile), the active profile with its fingerprint (factory, candidate or custom) and its backend, **Restore factory profile**, **Hold the active profile** and **Return to native**. A model's best beat is a candidate for the real runs, never a result; no profile is locked as the baseline, and the factory's beat stays 60 s until the eight steps of section 76.8 choose the next. At the page's back stand the

glossary and index (`tools/live_glossary.py`): every term in the words of the file it names, the ten organisms with their twenty scenarios, every one of the 1,107 muscles of the catalog by realm and family, and the sections where each is used.

CHAPTER 13

The Canonical Engine

One engine runs Omni-Compass, and every result in this repository comes from it. This page names it, gives its equations exactly as the code computes them, and names every other form as a variant. Where any document, manual, chart or filing states the equations differently, this page and the file it fingerprints are what the software runs.

13.1 The canonical engine: `symmetric_verified`

Name	`symmetric_verified` (`omnicompass/configurations.py`, `DEFAULT`)
Code	`omnicompass/core.py` (Python), `cpp/src/core.cpp` (C++ twin, sealed in `results/SEAL.json`)
Fingerprint	SHA-256 of `omnicompass/core.py`, recorded in `results/PREREGISTRATION.json` and `RELEASE_MANIFEST.json`; checked by `verify.py`
Evidence	every model, benchmark, live Kubernetes run and GPU harness in this repository

State: E (deviation), U (coherence), I[U] (unmet-need integral), S (structural stress), B and $\dot{B}$ (the bath).

```
v[eff]   = cos(ω[B] t / 2) · c · tanh(λ₀ + λ₁ (U − 0.5) + λ₂ S)
    ↪  (spinor closure, 720°)
dE/dt    = −α[E] E + β[int] + β[ext] + v[eff]
dU/dt    = μ U (1 − U²) − (dE/dt) / E[max] − λ[U] U + u
    ↪    (symmetric double well)
dI[U]/dt = (1 − U) − σ₁ E − δ S − λ[I] I[U]

dS/dt    = δ − αₛ S − (3/4) βₛ S²
    ↪    (gradient of Φ)
dB/dt    = Ḃ
dḂ/dt    = γ[c] δ S − (ω[B] / Q[B]) Ḃ − ω[B]² B
Φ(S)     = αₛ S² / 2 + βₛ S³ / 4 − δ S
```

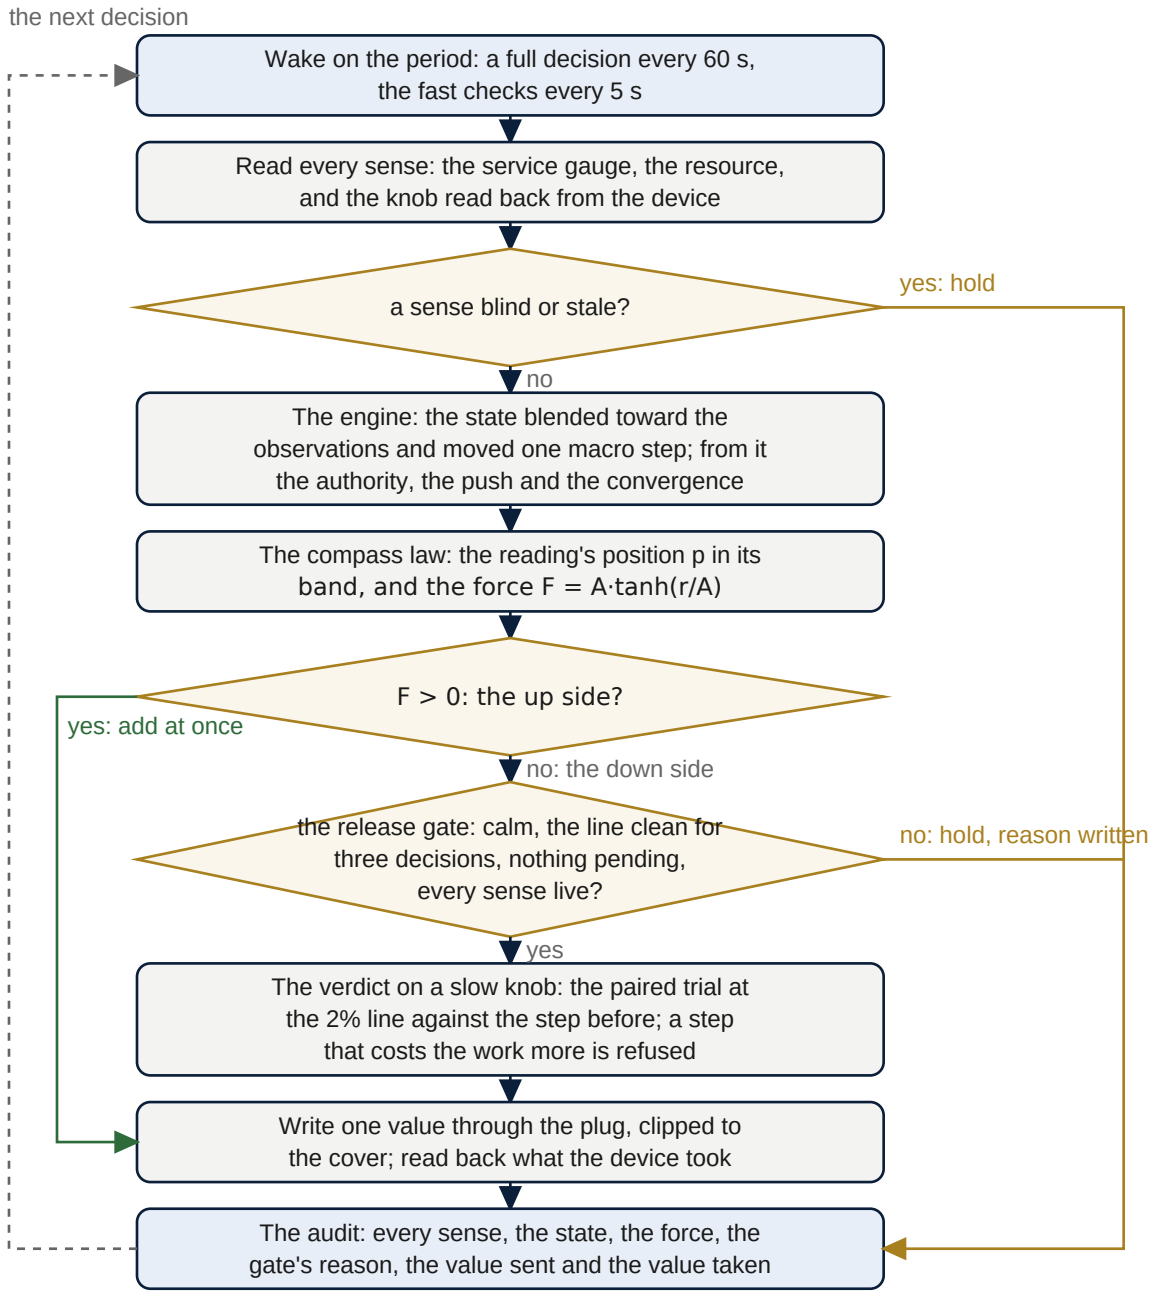

Figure 9. One decision of the governor. It wakes on its period, reads every sense, and holds if any sense is blind or stale: nothing is given back, and adding capacity is still allowed. The engine blends its state toward the observations and moves one macro step; the compass law turns the reading's position into a force. A positive force adds capacity at once, gated by nothing but the security hold.

A negative force must pass the release gate (calm, the line clean for three decisions, nothing pending, every sense live) and, on a slow knob, the verdict's paired trial at the 2% line. What survives is one write through the plug, read back, and one line in the audit that records every sense, the state, the force, the gate's reason and the value sent and taken, whether or not anything was written.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

u is the controller's command, `K[P] (target − U) − drift`, bounded by `U_AUTHORITY`; integration is RK4 with the macro and micro steps of `omnicompass/core.py`.

13.1.1 Mechanism identity

`results/MECHANISM_IDENTITY.json` (`tools/mechanism_identity.py`) fingerprints the mechanism M = (F, Theta, C, h, G, M[act], dt, A) component by component: state law, parameters, controller, observation map, authority law, actuator map, execution timing, shield. `verify.py` fails if any component changes without the record being rewritten. Every evidence claim names the mechanism id that produced it; "the eight-line engine" alone names none.

Configuration	Mechanism id	Role
`symmetric_verified`	`b10f1b4128ff7fc76b8865e0d1c486817fe56ec347f8d105bcaa657904cb61f2`	canonical
`printed_eight_line`	`623934cc31e964120aa7e8a22d17927fef9a7588e599b089b8ae545ec240ef12`	named alternative embodiment

On the frozen 500-fixture population (`benchmarks/core_evidence.py`, seed 223387268), both are executable and neither is a stand-in for the other:

	finite	CONVEY-5	CERT-10	mean final target error	mean integrated abs(u)	max abs(u)
`symmetric_verified`	500/500	500/500	500/500	7.48e-5	0.878	13.93
`printed_eight_line`	500/500	500/500	500/500	5.13e-6	11.79	18.87

The printed form reaches its target more tightly with about 13 times the control effort. The structure is Option A: one canonical configuration, one named alternative; no equivalence is claimed.

13.2 Variants

13.2.1 `printed_eight_line` *(the printed chart)*

Implemented in `omnicompass/configurations.py`, checked against the printed plate (`tests/test_engine_configurations.py`), **not benchmarked**: no result in this repository comes from it.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
v[eff]   = c · tanh(λ₀ + λ₁ (U − Uₜ) + λ₂ S)
    ↪    (no spinor factor)
dE/dt    = −α E + β[int] + β[ext] + v[eff]
dU/dt    = α (1 − U) − (dE/dt) / E[max] − k U (1 − U) + u
    ↪    (logistic)
dI[U]/dt = (1 − U) − σ₁ E − δ S

    ↪    (no λ[I] term)
dS/dt, dB/dt, dḂ/dt as in section 13.1
```

Differences from the canonical engine: logistic U instead of the symmetric double well; no spinor factor; a general target U_t; no λ[I] damping; α in place of α[E]. α[U] and k enter the printed form; they do not enter the canonical engine.

13.3 What would change this declaration

Promoting a variant to canonical needs, in one commit: the variant run through every harness beside the canonical engine, its results reported next to the canonical results, this page and `RELEASE_MANIFEST.json` updated, and the preregistration amended on record (`results/LOCK_AMENDMENTS.json`). Until then the canonical engine is `symmetric_verified`.

13.4 Open mathematical items (from `docs/FORMAL_STATUS.md` and the handoff)

- A global stability proof of the forced six-state system is not closed. What is held on the U channel is proved in `docs/TRACKING_THEOREM.md`: unsaturated exponential tracking; the saturated case under a drift bound that holds over the declared box (F[bar] = 16.86 < 25); the sampled-data bound of the executed RK4 controller; admissibility.
- Candidate routes: the Unified Circle Principle on a region; Theorem 5.6 of the Closed Structure, if its core maps onto (E, U, I[U], S, B).

13.5 For filings

Which form a patent or copyright filing claims as the principal embodiment is a decision for Dubra Software Inc. / The Omni-Compass LLC and its counsel. Whatever that decision, the software described by this repository runs the canonical engine of section 13.1, and a filing that claims the printed form should name `symmetric_verified` as the embodiment that has been implemented and tested, or the printed form should be benchmarked first (section 13.3).

CHAPTER 14

The Closed Circle: Why It Cannot Leave Its Compass

The governing principle is the Unified Circle Principle:

```
dX/dt = G(X),  X(0) in Omega
G(X) . n(X) <= 0 on the boundary of Omega        (the flow points inwa
    ↪ rd at the wall: nothing crosses)
grad L(X) . G(X) <= 0                            (the compass's energy
    ↪  L only falls)
=> lim X(t) in M*                                (every path settles i
    ↪ n the bottom of the compass)
```

In control engineering the second line is the Nagumo condition for an invariant set and the third is a Lyapunov function. Together they mean: anything that starts inside the container stays inside it, for every disturbance up to a known size, and comes to rest at the bottom. That is a certificate, not a test: it answers every case inside the walls at once.

In plain words. Picture a round valley with a fence around its rim. The first line says the valley has a shape: given where the system is, the equations say which way it rolls. The second line says that at the fence the ground always slopes inward, so nothing that starts inside can ever roll out, however it is pushed within the strength the fence was built for. The third line says there is a height, *L*, that only ever decreases along any path, so the system cannot circle forever at one level; it must keep descending. The conclusion follows: every path ends at the bottom, the set *M**. The engineering value of such a certificate is that it is not a sample of behaviours; it is a statement about all of them at once, inside the fence.

What is certified, and what is not. The certificate is about the engine's own state: the six numbers of Chapter 12 stay inside their walls and settle. It is not a certificate about the plant the engine governs, whose physics the engine does not contain; that is why every plant is tested paired against native (Part Seven), why the compass law clips every write to the knob's cover (Chapter 30), and why the shield between the engine and the levers is tested separately on two million adversarial cases with zero violations (`tests/test_shield_properties.py`) and the C++ engine soaked on one hundred million decisions

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

with no failure (`results/SOAK.json`). The mathematics closes the brain; the harness, the cover, the verdict and the paired receipts close the hand.

The engine's states are each closed in this sense: the deviation tank drains faster than it can fill; the alignment's cubic walls push back from far out; the memory forgets; the bath's friction settles it. The rule behind all four is the compass's east-west line: what flows out (drain, damping) must always be able to match what flows in (drive). The formal status of each statement, what is proved, what is tested and what is conjecture, is written out in `docs/FORMAL_STATUS.md` and `docs/TRACKING_THEOREM.md`, and the theory chapters of this book (The Unified Circle Principle, Closing the Circle in the Engine) give the derivations.

What the certificate buys an operator, in practice. Three things. The engine cannot run away: there is no input, no sequence of readings and no fault in a sense that drives its internal state to infinity or into oscillation that grows, because the walls are part of the equations and not a check bolted on afterwards. The engine cannot hold a grudge: the memory state forgets at a fixed rate, so a bad hour does not bias the next day, and a governor restarted after a kill starts from the same rest state the certificate names. And the engine's behaviour under any disturbance smaller than the fence is the same kind of behaviour, a descent to the bottom, so a test on one plant's readings says something about the engine on another's; what it does not say, and what no mathematics of the engine alone could say, is how the plant answers, which is why the paired runs exist. An underwriter reading this section should take from it exactly this much: the part of the system that makes decisions is bounded by proof; the part of the system that carries them out is bounded by the cover, the gates and the hand-back, each tested; and the part that is the customer's own plant is measured, never assumed.

The compass. The Omni-Compass rose carries the whole Greek alphabet, Alpha to Omega: the complete set, in a ring whose end runs back into its beginning. Its north-south axis is polarity: Alpha and plus at the top, Omega and minus at the bottom, the two poles of the alignment's double well. Its east-west axis is flow: Beta and the push outward on one side, Gamma and the pull inward on the other, the drive and the damping. The spiral at the center is the attractor every path winds into. The ring closing on itself is the return: when Omni-Compass stops, every lever returns to where it began.

CHAPTER 15

Closing the Circle in the Engine

Each state of the engine was checked against the closed-circle conditions:

State	Closed?	Why
E, deviation	closed	it drains at rate α[E] while its inputs are bounded (the drive is capped by tanh)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

State	Closed?	Why
U, alignment	closed	the cubic term μ U (1 − U²) pushes back hard from far out
I[U], memory	closed	it forgets at rate λ[I]
B, the bath	closed	the friction ω[B] / Q[B] settles it
S, the basin	closed on the positive side; open on the negative side below an unstable ridge	Φ(S) carries a cubic term, so the landscape falls away below the ridge (at S = −3.5 with the default parameters)

Three openings were found and each has its closure:

1. **The basin's negative side.** A quartic term in Φ(S) would give the compass a wall on both sides. This changes the frozen engine and is a new version with its own proof.
2. **The outer loop.** The frozen live governor computes the push and pull u and uses it as a convergence signal; it does not send u to a lever. The compass closes this loop: reading, force, plug, lever, read-back. On the modelled card this is the difference between +0.1% and several percent of work per energy (the one-wire governor against the corrected two-wire compass, `results/sim/gpu_two_wire/`).
3. **The corner.** clip() is a hard stop; tanh is its smooth form. The compass uses tanh.

What closing the loop has shown since. The compass law of the second opening is the law every result in the manual was made on: it was frozen as Omni v1 on 5 October 2026 with its proofs untouched, grown to the 945-muscle catalog as v2, and given one gate as v3, the slack gate on speed knobs, after the v2 realms read a service tradeoff on the Physics realm and the tower. That gate is the closed circle applied to a muscle's physics: an axis that is busy more than half the time at full speed has no slack to spend, and a law that spent it anyway would be spending energy for nothing; with the gate, every organism reads superior within its guardrails and zero muscles read LOSS (`results/realms/REALMS.md`). On real software the same law, read through the plug and the read-back, is the law of the Kubernetes, database, broker and cache tables, with their gains and their losses. The first opening, the basin's negative side, remains open and documented: it would be a new version with its own proof, and no result depends on it.

CHAPTER 16

The Tracking Theorem

This page proves the internal tracking result of the canonical engine (`symmetric_verified`, mechanism id in `results/MECHANISM_IDENTITY.json`) in four steps, from the continuous law to the code as executed. Each statement carries one evidence class (see `docs/EVIDENCE_LEDGER.md`): **T** proved here, **V** checked by computation over a finite, frozen set (`tools/tracking_bounds.py` → `results/TRACKING_BOUNDS.json`).

What this page establishes is **internal**: inside the declared model, the controller conveys U to its target σ. It does not establish that σ is the right target for any outside plant, that the telemetry map is right, that any actuator mapping (HPA, GPU, CPU) is right, any energy saving, production performance, or stability of the whole forced six-state system. Target correctness and target conveyance are separate obligations; this page carries only the second.

16.1 Setting

U channel of equation (2): `dU/dt = f[U](x, t) + u`, with the uncontrolled drift

```
f[U](x, t) = μ U (1 − U²) − (dE/dt) / E[max] − λ[U] U
```

and the bounded cancellation-plus-proportional controller (`omnicompass/core.py`, `control_command`)

```
u = sat(−f[U](x, t) + K[P] (σ − U)),   sat(v) = max(−u[max], min(u[max
    ↪ ], v)),   K[P] = 12, u[max] = U_AUTHORITY = 25.
```

Tracking error `e = U − σ`, σ ∈ {−1, +1}.

16.2 Theorem 1 (T). Unsaturated tracking

On the unsaturated region `Ω[unsat] = { x : |−f[U](x, t) − K[P] e| ≤ u[max] }`, `de/dt = −K[P] e`. Along any interval spent in `Ω[unsat]`, `e(t) = e(t₀) exp(−K[P] (t − t₀))`, and `V = e²/2` satisfies `dV/dt = −K[P] e² < 0` for `e ≠ 0`.

Proof. Inside `Ω[unsat]` the saturation is inactive, so `dU/dt = f[U] − f[U] + K[P] (σ − U) = −K[P] e`; since σ is constant, `de/dt = dU/dt`. The solution and `dV/dt = e de/dt = −K[P] e²` follow. ∎

This is a statement about intervals inside `Ω[unsat]` only; it is not global convergence.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

16.3 Theorem 2 (T). The saturated case, under a declared drift bound

Assumption D. Along the trajectory, `|f[U](x(t), t)| ≤ F[D] < u[max]`.

Under D:

1. If saturation is active with `e < 0`, then `u = +u[max]` and `de/dt = f[U] + u[max] ≥ u[max] − F[D] > 0`; symmetrically for `e > 0`. So `dV/dt ≤ −(u[max] − F[D]) |e| < 0` wherever saturation is active.
2. With Theorem 1, `V` is strictly decreasing wherever `e ≠ 0`, saturated or not; `e` never changes sign (at `e = 0` the command is unsaturated because `F[D] < u[max]`, so `e = 0` is an equilibrium of the error dynamics).
3. Any saturated stretch ends within `(|e(t₀)| − e*) / (u[max] − F[D])` time units, `e* = (u[max] − F[D]) / K[P]`; the ball `|e| ≤ e*` lies inside `Ω[unsat]` and is forward invariant, and inside it the decay is exponential at rate K[P].

Proof of 1. Saturation with `u = +u[max]` means `−f[U] − K[P] e > u[max]`, so `−K[P] e > u[max] + f[U] ≥ u[max] − F[D] > 0`, so `e < 0`, and `de/dt = f[U] + u[max] ≥ u[max] − F[D]`. The other side is symmetric. 2 and 3 follow from 1 and Theorem 1, and `|−f[U] − K[P] e| ≤ F[D] + K[P] |e| ≤ u[max]` on the ball. ∎

Where D holds (T). On the declared box — parameters in `PARAMETER_RANGES`, `E₀` in [0, 1], `|U| ≤ 1.1` — equation (1) keeps E in `[(β − c)/α[E], (β + c)/α[E]]` widened to hold E_0 (the right side of (1) points inward at both ends, because `|v[eff]| ≤ c`), so `|E| ≤ 7/4.2`, `|dE/dt| ≤ 4.2·|E| + 2 + 5 ≤ 14`, and

```
F[D] = 6 · 2/(3√3) + 14 / 1 + 0.5 · 1.1 = 16.86 < 25 = u[max].
```

Because e keeps its sign and `|e|` does not grow (continuous time), U stays between U_0 and σ, so `|U| ≤ 1` and the box is self-consistent for the nearest-basin target. **Theorem 2 therefore holds globally over the declared box, in continuous time.** The actuator can still saturate: `|raw| ≤ F[D] + K[P] |e₀|` can exceed 25 when `|e₀|` is near 1.

Checked (V). Over the 500 frozen fixtures: observed `max |f[U]|` = 6.84 (nearest target), 7.01 (wrong target), each under that fixture's own bound (max 8.99) and under 16.86; saturated micro steps 0 of 100 000 (nearest target), 5 of 100 000 (wrong target).

16.4 Theorem 3 (T with a computed constant). The executed sampled-data controller

The code does not run the continuous law. Per micro step `h = MICRO_DT = 0.01`, it computes `uₖ` from `xₖ`, holds it through the four stages of one RK4 step (zero-order hold), and takes `xₖ₊₁ = F[h](xₖ, uₖ)`. There is no overwrite of U after the step, no projection onto a basin, no state replacement.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Integrating the U equation over one held interval,

```
e_{k+1} = e_k + h (f[U](x_k) + u_k) + ∫[t_k, t_k+h] (f[U](x(t)) − f[U](x_k)) dt
    ↪  + τ_k
```

with τ_k the RK4 truncation error. Unsaturated, $f[U](x_k) + u_k = -K[P]\ e_k$, so

```
e_{k+1} = ρ e_k + d_k,   ρ = 1 − h K[P] = 0.88,   |d_k| ≤ (h²/2) sup|df[U]/d
    ↪ t| + |τ_k| =: ε[h].
```

Then by induction $|e_k| \le \rho^k\ |e_0| + (1-\rho^k)/(1-\rho) \cdot \varepsilon[h]$, and the error enters and stays in the neighbourhood $|e| \le \varepsilon[h] / (1-\rho)$.

The proof above is exact given ε[h]. **ε[h] itself is computed, not proved (V):** the largest $|d_k|$ over every micro step of the 500 frozen fixtures is 0.00378 (nearest target), giving the ultimate bound 0.0315, inside `BASIN_TOL` = 0.10 that CONVEY-5 and CERT-10 test. With the target aimed wrong, ε[h] = 0.0243 (dominated by the long transient, which includes the 5 saturated steps) and the bound 0.20 is wider than the basin — a conservative bound; the fixtures still certify 500 of 500.

Proved since 19 October (T, computer-assisted; `docs/ENGINE_PROOFS.md`, claims U2 to U5). Over the whole declared box, not the fixtures: every unsaturated micro step satisfies $|e_{k+1}| \le (\rho + b)|e_k| + a$ with $a \le 0.006495$ and $b \le 0.02399$. These are interval enclosures with outward rounding of the stage-to-stage drift differences, bounded by the mean value theorem. So the ball $|e| \le a / (1 - \rho - b) \le 0.0677$ is entered and never left, inside `BASIN_TOL`. Every saturated step moves U toward σ by at least 0.0868 and never past it. From any admissible start the error is in the basin within 119 of the run's 200 micro steps. The fixtures' 0.0315 lies inside the proved 0.0677.

What the discrete execution does **not** inherit: the continuous monotone decay. Within the band, $|e|$ grew on 27 061 of 100 000 micro steps and e changed sign 747 times — the sampled controller dithers inside $\varepsilon[h] / (1-\rho)$.

CONVEY and CERT. They are dwell checks against a declared neighbourhood ($|U - \sigma| \le 0.10$ for 5 and 10 consecutive macro steps). Theorem 3 says why they pass when the bound sits inside the neighbourhood. They are not an external certification.

16.5 Theorem 4 (T continuous; V discrete). Admissibility

Admissible set for a fixture with parameters p and initial state x0:

```
A = { x : E ∈ [E[lo], E[hi]],  |U − σ| <= |U_0 − σ|,  S between S_0 and
    ↪ S_+(p) }
```

`E_lo, E_hi` as in Theorem 2; S_+ the stable root of equation (6).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Continuous (T).** A is forward invariant: E by the inward-pointing field at both ends; U by Theorem 2; S because equation (6) is the one-dimensional gradient flow of Φ, monotone toward S_+ from any $S_0 > S_-$ (`s_admissibility` in `results/core_evidence.json`: 500 of 500 fixtures start above `S_minus`).
- **Discrete (V).** For the executed map `F[h](x, C(x))`, every micro step of every fixture: $x_k \in A$ implied $x_{k+1} \in A$ — 0 failures in 100 000 steps, target nearest or wrong. This is a finite verification on the frozen fixtures.
- **Discrete (T, since 19 October).** Over the whole box, for the executed RK4 step (`docs/ENGINE_PROOFS.md`):
  - E stays in its interval (E1, exact linear arithmetic in z3), and so does every stage (E2);
  - S moves toward S_+ and never past it (S1);
  - U stays within `max(|U₀ − σ|, 0.0677)` of σ (U3, U4);
  - I[U] stays in its interval for any bounded drive (I1).

16.6 What remains open (O)

- Global stability of the forced six-state system. E, U, S and I[U] are proved bounded under the executed step (`docs/ENGINE_PROOFS.md`). Not proved: the bath B, which nothing reads back, and convergence of E, I[U] and B to a set.
- CERT-10 for every fixture in the box: the proved entry bound (119 micro steps) leaves 9 macro steps inside the basin, not 10. Every one of the 500 fixtures certifies (V).
- The inheritance / intertwining residual against an outside plant: instrumented (`tools/gpu_reps.py`, representation fidelity), not yet measured on a real card.
- The printed configuration (`printed_eight_line`) is not covered by this page: its U drift is logistic, not the double well, and needs its own bound (`docs/CANONICAL_ENGINE.md`).

CHAPTER 17

The Engine's Machine-Checked Proofs

This page states what is proved about the engine that stands, how each proof is checked by a machine, and what is still open. Every proof is about the algorithm the engine executes, over every input in its declared set, never over samples. No engine file was changed to make them: the proofs read the engine's own constants. `python3 tools/prove_engine.py` checks all of them in under a second and writes `results/ENGINE_PROOFS.json`. `tests/test_engine_proofs.py` runs it on every push, and fails a push where any claim is not proved, where a claim's premises admit no case (a vacuous proof), or where the stored record differs from the one the proofs produce.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

`tests/test_engine_properties.py` then runs the engine's own code on several thousand generated cases and checks every proved property on each case, with the proved constants. A failure there would mean the proof and the code disagree.

Evidence class of everything on this page: **T**, proved. Two machine methods carry the proofs:

- **SMT (the z3 solver).** A claim P is proved when the solver shows that "the premises and not P" has no solution (unsat). Before that, the solver confirms that the premises alone have a solution, so no proof is vacuous. tanh enters only through true facts about it:
  - $-1 < \tanh x < 1$;
  - $\tanh x$ has the sign of x;
  - $\tanh$ is increasing;
  - $\tanh$ is 1-Lipschitz: $|\tanh x - \tanh y| \le |x - y|$.

So whatever is proved for every function with these facts holds for tanh.

- **Interval arithmetic with outward rounding** (mpmath's interval arithmetic at 40 digits). Every enclosure computed is a true bound of the quantity over the whole box, rounding included. The U axis is cut into 96 cells for a tight enclosure. tanh of an interval is the hull of tanh at its two ends, which is exact because tanh is increasing.

17.1 The compass law (`omnicompass/compass_law.py`, `CompassLaw.force`)

For every reading position p, velocity estimate v, gains $k_p > 0$ and $k_d \ge 0$, authority $A > 0$ and walls $0 < w_{low} < centre < w_{high} < 1$, write $raw = k_p (p - centre) + k_d v$. The force is:

- $f = A$ when $p \ge w_{high}$;
- otherwise $f = A \tanh(raw / A)$, set to 0 when that value is negative while $v > 0$ and $p > centre$.

Claim	Statement	Result
C1	$-A \le f \le A$	proved
C2	$p \ge w_{high} \Rightarrow f = A$ (fail up at once)	proved
C3	$f < 0 \Rightarrow$ not ($v > 0$ and $p > centre$): it never takes back while the reading climbs above the centre	proved
C4	with $v = 0$: $f < 0$ below the centre, $f > 0$ between the centre and the wall, $f = 0$ at the centre	proved
C5	for one v: $p_1 \le p_2 \Rightarrow f(p_1) \le f(p_2)$ (no inversion anywhere, the wall and the take-back rule included)	proved
C6	at one p: $v_1 \le v_2 \Rightarrow f(v_1) \le f(v_2)$	proved

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Claim	Statement	Result
C7	inside the band, away from the wall and the take-back rule: abs(f(p_1) − f(p_2)) ≤ kp abs(p_1 − p_2) (smooth, never a hammer)	proved
C8	the default damping kd = max(0, 2 √(kp τ / Δt) − 1) Δt is never negative	proved

17.2 The plug's clip (`Plug.write`)

Claim	Statement	Result
P1	lo ≤ hi ⇒ lo ≤ clamp(x) ≤ hi: every value sent lies inside the cover	proved
P2	lo ≤ x ≤ hi ⇒ clamp(x) = x: nothing inside the cover is clipped	proved
P3	clamp(clamp(x)) = clamp(x)	proved

17.3 The verdict's rule (`omnicompass/verdict.py`, judge "interval")

A trial step is allowed when three things hold: it does not read LOSS (no 95% interval wholly above zero), its median cost mk ≤ min(m_0, m[native]) (1 + tol), and the largest estimated change is at most τ = ln(1 + tol).

Claim	Statement	Result
V1	allowed ⇒ every interval's lower end ≤ 0: an allowed step never reads LOSS against either reference	proved
V2	allowed ⇒ every estimated change ≤ τ and mk ≤ m_0 (1 + tol)	proved
V3	allowed ⇒ mk ≤ m[native] (1 + tol): stepwise, steps cannot add up past the cost first measured at native	proved

17.4 The core engine as executed (`omnicompass/core.py`)

The engine does not run the continuous law. Per micro step h = 0.01 it:

1. computes the command u[k] from x[k];
2. holds u[k] through the four stages of one RK4 step;
3. takes x[k+1] = F_h(x[k], u[k]).

Theorems E1 to B1 are about that map, over the declared box:

- every parameter in `PARAMETER_RANGES`;
- E_0 and I_0 in [0, 1];
- U_0, S_0, B_0 and B'_0 in [−1, 1], with S_0 above the unstable root S_- (theorem S1's premise; the declared box has starts below S_-, from which S leaves every bound, and they are outside every claim);

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- the target σ = ±1, nearest or aimed wrong.

Claim	Statement	Method	Result
E1	E[k] ∈ [min(0, (β − c)/α[E]), max(1, (β + c)/α[E])] ⇒ E[k+1] in the same interval, for every value v[eff] takes at the four stages (abs(v[eff]) ≤ c)	SMT, exact linear arithmetic	proved
E2	every RK4 stage of E lies in that interval widened by 0.13	SMT	proved
I1	for any drive F[i] ∈ [F[lo], F[hi]] at the four stages, I[k] ∈ [min(I_0, F[lo]/λ[I]), max(I_0, F[hi]/λ[I])] ⇒ I[k+1] in it too	SMT, nonlinear	proved
S1	S moves toward its stable root S_+ and never past it: with L = sup abs(dṠ/dS) on the S box, every RK4 stage stays on the same side of S_+ when h L < 1	intervals: L ≤ 1.953, h L ≤ 0.0196	proved
U1	the drift is below the actuator's limit on the whole stage box: sup abs(f[U]) ≤ F[D] = 16.32 < 25	intervals	proved
U2	every unsaturated micro step: abs(e[k+1]) ≤ (ρ + b) abs(e[k]) + a, ρ = 1 − h K[P] = 0.88, a ≤ 0.006495, b ≤ 0.02399	intervals and the mean value theorem	proved
U3	the ball abs(e) ≤ r* = a / (1 − ρ − b) ≤ 0.0677 is entered and never left. It lies inside the basin (0.10) and inside the unsaturated region. Beyond abs(e) = 0.0076 the error never changes sign, so U never overshoots σ by more than r*. Every RK4 stage of U lies in the stage box [−1.2, 1.2]	intervals	proved
U4	every saturated micro step moves U toward σ by at least h (25 − F[D]) ≥ 0.0868 and at most 0.4132. Saturation needs abs(e) > 0.7238, so the step never passes σ	intervals	proved
U5	from any admissible start (abs(e_0) ≤ 2, the target aimed wrong included), abs(e) ≤ 0.10 within 119 micro steps (95 unsaturated, 24 saturated) of the run's 200	intervals	proved
Claim	**Statement**	**Method**	**Result**
B1	the bath (B, B′), a linear damped oscillator driven by S, x′ = A x + (0, γ[c] δ S) with A = [[0, 1], [−ω[B]², −ω[B]/Q[B]]]: for every (ω[B], Q[B]) in the box the	intervals and the remainder of e^x	proved

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Claim	Statement	Method	Result
	spectral radius of its RK4 step R(hA) is at most 0.99995, so it shrinks by at least 5.0×10^{-5} every micro step, stays bounded under the bounded S, and forgets its start		

How U2 is proved. Unsaturated, the command cancels the drift at x[k] exactly, so $k_1 = -K[P]\, e[k]$ and $e[k+1] = \rho\, e[k] + (h/6)(2\, D_2 + 2\, D_3 + D_4)$, where D[i] is f[U] at stage i less f[U] at x[k]. By the mean value theorem on the segment to each stage:

```
abs(D[i]) ≤ g[U] abs(ΔU[i]) + g[E] abs(ΔE[i]) + g[S] abs(ΔS[i]) + g[t]
    ↪  abs(Δt[i])
```

with the partial-derivative bounds g taken over the stage box. The stage displacements are bounded by the step times the stage slopes (K[E] for E, K[S] for S, K[P] abs(e) + abs(D) for U), which gives abs(D[i]) ≤ A[i] + B[i] abs(e) by recursion over the four stages. The enclosures are:

- g[U] ≤ 35.42, g[E] = 4.2, g[S] ≤ 10.0, g[t] ≤ 12.5;
- K[E] ≤ 12.55, K[S] ≤ 4.99.

A floating-point allowance of 10^{-12} is added to a for the binary64 arithmetic the engine runs in.

How B1 is proved. For Q[B] ≥ 1/2 the eigenvalues λ of A have real part $-\omega[B]/(2Q[B])$ and modulus ω[B] (a complex pair, or the double root at Q[B] = 1/2). The RK4 step multiplies each eigen-direction by R(hλ), $R(z) = 1 + z + z^2/2 + z^3/6 + z^4/24$, and the remainder of the series of e^z gives

```
abs(R(z)) ≤ e^(Re z) + abs(z)⁵/120 · e^abs(z)
```

The bound rises with Q[B], so it is evaluated at the largest Q[B] over 400 cells of ω[B] with outward rounding; its largest value, 0.99995, is the spectral-radius bound. A spectral radius below 1 makes the forced linear map bounded for every bounded input, and S is proved bounded (S1).

What this closes. `docs/TRACKING_THEOREM.md` carried three open items:

- a proved ε[h] over the declared box;
- discrete invariance over the box;
- an interval-arithmetic proof of the admissible set.

The first two are now proved for E, U, S and I[U], and the bath is proved stable (B1). Theorem 3's ultimate bound is proved: 0.0677 against the 0.0315 the 500 fixtures reached, which lies inside it. Theorem 4's discrete half moves from V (checked on fixtures) to T for those four states. U5 also proves that CONVEY-5 passes for every admissible fixture: at least 9 of the 20 macro steps end inside the basin.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

17.5 What is still open

- **CERT-10 for every fixture.** U5's bound guarantees 9 macro steps inside, not 10. Every one of the 500 frozen fixtures certifies (V), but a proof for the whole box needs a tighter entry bound: a, b and q are worst-case constants over the whole box.
- **The bath's amplitude as a number.** B1 proves the bath is stable and bounded for every parameter in the box; an explicit bound on abs(B) needs a Lyapunov function for each (ω[B], Q[B]), and is not computed here. The bath is never fed back into any other state (no equation of E, U, I[U] or S reads it).
- **Convergence of the forced six-state system as a whole.** Bounded is proved for E, U, S and I[U]; convergence of E, I[U] and the bath to a set is not.
- **Starts below S−.** From there S leaves every bound (the basin's negative side, `docs/book/THEORY.md`). They are outside every claim on this page, and the quartic closure named in the theory is the engine change that would remove them.
- **The live governors** (`omni_controller/*`) are proved here only through the parts they share: the compass law, the plug's clip and the verdict. Their Kubernetes, GPU and cloud wiring is tested, not proved.

CHAPTER 18

The Conveyance Law

18.1 What the manuscript says, read as mechanism

Source	Text	Mechanism
Ch. 29 §8	"E[system] = E + U + S + B … dE_system/dt = 0 (over full cycle). Energy redistributes. Energy reorganizes. Energy does not diverge."	The budget (site watts, cluster cores) is **conserved**: it is moved between organs, never created.
Ch. 31 §4	"Redistribution B acts as mediator between the baths. When E grows locally, B increases to distribute gradients."	Budget flows **down the gradient of need**: from organs holding surplus to organs in deficit.
Ch. 31 §5	"eigenvalues of the coupled system must remain bounded … $Re(\lambda_i) \leq 0$"	The flow must have a proof of convergence, not a tuned damper.
Ch. 30 §5-7	"Redistribution surge … channels stored deviation into expansion … controlled release … No discontinuity."	A **reserve** is held and released **continuously** to organs at their limit. There is no on/off.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Source	Text	Mechanism
Ch. 29 §6	"Backpressure develops through S … Compression is … structured inward rotation."	When need falls, surplus is **pulled back** smoothly. Budget nobody needs is not spent.
App. J	"the engine can only act through what you expose"	Organs keep their own mechanisms. The law sets only each organ's share of the budget.

18.2 The law

Notation.

- Organs i = 1..n share a budget A.
- Organ i holds allocation a_i and has need d_i: the budget that serves its work at the engine's utilisation target ρ.
- Its deficit (local deviation) is

$e_i = d_i / (\rho\, a_i) - 1$ ($e_i > 0$: needs juice; $e_i < 0$: holds surplus)

The redistribution mediator:

$da_i/dt = \kappa\, a_i\, (e_i - \bar{e})$, $\bar{e} = \Sigma_j\, a_j\, e_j / A$

18.3 Properties and proofs

P1. Conservation.

- $\Sigma_i\, da_i/dt = \kappa\, (\Sigma_i\, a_i e_i - \bar{e}\, \Sigma_i\, a_i) = \kappa\, (A\, \bar{e} - \bar{e}\, A) = 0$.
- The budget is moved, never created, as in Ch. 29 §8.

P2. Gradient flow with a Lyapunov function.

- Substitute e_i: $a_i(e_i - \bar{e}) = d_i/\rho - a_i\, D/(\rho A)$, where $D = \Sigma\, d_i$.
- So $da_i/dt = (\kappa/\rho)(d_i - a_i\, D/A)$.
- This is the Shahshahani gradient on the simplex $\Sigma\, a_i = A$ of $F(a) = \Sigma_i\, (d_i/\rho)\, \ln a_i$. The Shahshahani metric weights by $1/a_i$, and $\partial F/\partial a_i = d_i/(\rho\, a_i)$, so $a_i(\partial F/\partial a_i - \text{mean})$ is exactly the flow above.
- Along the flow $dF/dt = \Sigma_i\, (1/a_i)(da_i/dt)^2 \cdot (\rho/\kappa) \geq 0$.
- F is strictly concave, so F is a Lyapunov function and the flow cannot cycle.

P3. Global exponential convergence.

- The ODE in P2 is linear: $a_i(t) = a_i^* + (a_i(0) - a_i^*)\, e^{(-\kappa D t/(\rho A))}$, with $a_i^* = A\, d_i/D$.
- The Jacobian is $-(\kappa D/(\rho A))\, I$ on the simplex, so every eigenvalue is $-\kappa D/(\rho A) < 0$. This meets $\mathrm{Re}(\lambda) \leq 0$ of Ch. 31 §5 strictly.
- At the equilibrium every organ has the same deficit $e^* = D/(\rho A) - 1$. None is starved while another idles.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- `replicator_step` integrates it exactly, in closed form, for any step size.

P4. Bounds (floors, ceilings, the budget).

- Allocations are projected onto $\{lo_i \le a_i \le hi_i, \Sigma\, a_i \le A\}$.
- The projection is water-filling: organs at a bound keep it, and the rest share the remainder in proportion.
- Budget an organ cannot use (it is at its need or its ceiling) is not spent.

P5. Reserve and surge.

- The dual-bath rate channel (the rate tracker) projects the rise in need over one actuation delay: $R = \Sigma_i \max(0, \dot{d}_i)$, capped at $A/2$. R is held back.
- After the flow, R is released continuously to organs whose deficit stays positive, in proportion to their shortfall and up to their ceilings.
- This is the controlled release of Ch. 30: continuous state, no switch.

18.4 Evidence

Mathematics in code. `tests/test_conveyance.py` (in `verify.py`) checks 20,000 random systems:

- P1 conservation to 1e-9;
- P2, F never decreases;
- P3, the trajectory equals the closed form;
- P4, bounds and budget.

It also runs 2,000 systems over 30 steps and checks the full law never exceeds the budget or breaks a floor. That test found and fixed one real bug: an organ whose need fell below its device floor was given a ceiling under that floor.

The model (class S). `hardware/site_exchange.py`: four GPU groups of 16 H100-class GPUs share one site budget (MLPerf gamma). Held-out seed 929292, 48 scenarios per budget. Results: `results/hardware/SITE_EXCHANGE_HELDOUT_*.json`.

Site budget (share of TDP)	70%	60%	50%
Site-budget violation minutes, native / independent / **conveyance**	10.5 / 1.5 / **0**	45.6 / 10.5 / **0**	106.1 / 31.3 / **0**
Energy (kWh), native / static split / independent / **conveyance**	142.5 / 117.6 / 104.1 / **103.8**	139.1 / 107.9 / 103.5 / **102.0**	127.3 / 97.1 / 101.0 / **96.4**
Backlog minutes, static split (the arm that also keeps the budget) / **conveyance**	32.0 / **1.0**	89.7 / **8.9**	187.3 / **72.2**

Reading.

- **Keeping the budget.** Conveyance is the only dynamic arm that never exceeds the site budget.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Energy.** It uses the least energy at every budget.
- **Against the only other arm that keeps the budget (static split):** 31-115 fewer backlog minutes.
- **At tight budgets, native and independent sizing show less backlog,** but only by drawing power over the site limit for 10-106 minutes, which in a facility trips breakers.
- **When the budget is below total need,** conveyance shares the shortage in proportion to need. That is the unique stable point of P3: fair, and not a choice of weights.

CPU and GPU on one budget. `hardware/node_exchange.py`: the same law with CPU organs beside the GPU organs. Four groups, each two 8-GPU servers (16 H100-class GPUs, 4 CPU sockets); each unit of GPU work needs 0.35 of the CPUs at full clock to feed it; demand 1.6x the plant traces (the GPUs are held back by the budget, not by work). Arms:

- **S** today's practice: every GPU at one fixed cap low enough that the site fits even with every CPU at maximum;
- **XM** conveyance among the GPUs, counting the CPUs' last measured draw;
- **XC** conveyance over CPU and GPU organs together: each CPU group is held to the clock its feeding work needs, and the watts it no longer holds flow to the GPU groups in deficit.

Seed 515151, 24 scenarios, our own model (class S). Results: `results/hardware/NODE_EXCHANGE_*.json`. XC against S, paired, each a raw change with its sign (work served up, backlog and latency down: more work and faster, GAIN):

Site budget (share of GPU TDP + CPU maximum)	60%	70%	80%
Work served	**+5.7%**	**+3.6%**	**+1.4%**
Backlog minutes	−15.8%	−27.5%	−17.8%
95th-percentile latency factor	−39.6%	−43.6%	−35.2%
Site-budget violation minutes, native / S / XM / **XC**	195.8 / 0 / 3.9 / **0**	140.9 / 0 / 6.2 / **0**	61.8 / 0 / 5.3 / **0**

Reading.

- **More work from the same building.** The tighter the budget, the more the CPUs' unused watts are worth to the GPUs.
- **Holding the CPUs is what makes the hand-over safe.** Counting the CPUs' measured draw (XM) serves about as much, but goes over the budget for 4-6 minutes in every setting: a CPU can rise between one reading and the next. XC holds each CPU to its allocation, so the watts it gives up are really free, and it never goes over.
- **Most of the gain is the CPUs' reserve, not their clock.** Against XM, XC gains ~1% work per kWh; against S, the watts a fixed plan must keep for CPUs that might peak are what the GPUs receive.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- The same holds for the least and most favourable MLPerf gamma fits, and for CPU shares 0.2 and 0.6 (2.3% to 4.2% more work at the 70% budget), `tests/test_node_exchange.py` checks N1-N4 in `verify.py`.

18.5 What is not claimed

- This is our own model (class S) on declared device physics, never offered as proof of a physical saving.
- The live levers that would carry it are GPU power limits (`nvidia-smi -pl`, DCGM), RAPL package limits, and pod CPU limits under a namespace budget. They exist in `omni_controller/muscles.py`, but the exchange between them has not run on hardware.

CHAPTER 19

Formal Status of the Mathematics

Not a global-stability proof of the forced six-state system. For exact domain assumptions and machine-proof obligations read `docs/ENGINE_PROOFS.md`, then `docs/TRACKING_THEOREM.md` and `docs/EVIDENCE_LEDGER.md`. A claim called T is conditional on the specified solver/interval-arithmetic certificate, equations, numerical semantics and parameter box; this summary does not independently rerun those certificates.

Held:

- Isolated S-flow is the gradient of Phi (same formula in both cores).
- (T) Unsaturated: dU/dt = KP (sigma − U); V = e²/2 has dV/dt = −KP e² on that channel (Theorem 1).
- (T) Saturated, with the U drift bounded by F[bar] < U_AUTHORITY: V decreases wherever e ≠ 0; over the declared parameter box F[bar] = 16.86 < 25, so this holds over the box in continuous time (Theorem 2).
- (T, constant computed) Sampled-data RK4 controller: e_(k+1) = 0.88 e_k + d_k; with epsilon_h computed over the frozen fixtures (V), the ultimate bound 0.0315 lies inside the 0.10 basin (Theorem 3).
- (T continuous, V on frozen fixtures; conditional computer-assisted T for named coordinates) Admissibility: the later `docs/ENGINE_PROOFS.md` states E1–E2 (E), S1 (S), I1 (I[U]) and U1–U5 (U) over its declared admissible start set, with outward-rounded intervals / SMT obligations. The RK4 sampled U-error ultimate bound is at most 0.0677 on that set. This is **not** the older claim of monotone discrete U error and not a global closed-loop external plant theorem.
- (T conditional on the named engine proof) B1 bounds the damped bath under bounded S; it does **not** supply an explicit numerical bath-amplitude bound or convergence of the full forced system.

Open:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- Independent rerun and machine checking of the stated whole-domain certificates on the current frozen engine, including exact hypotheses, floating-point semantics and non-vacuous premises. The **older blanket open statement** about all discrete bounds is superseded only for E1–E2, S1, I1, U1–U5 and B1 on their declared domains; it is not a new proof of unrestricted six-state convergence.
- CERT-10 for every start in the admissible domain; the current worst-case U5 entry argument guarantees at least nine macro-steps, not ten. Starts below S− are excluded.
- Inheritance embedding / intertwining residual against a real plant (Closed Structure Def. 11.1): instrumented in the GPU bench (`tools/gpu_reps.py`, representation fidelity), not yet measured on a card.
- Mapping of monograph Theorem 5.6 onto (E,U,I[U],S,B).
- A tracking bound for printed_eight_line (logistic U drift).

Default core remains symmetric_verified (mechanism id in `results/MECHANISM_IDENTITY.json`).

CHAPTER 20

The Max, Formally: Definitions, Guarantees and Measures

This page states the engine's default brain, the max (`realms/compass_arm_v5.py`, `V5CFG`, engine omni-v5 by `tools/omni_version.py`), in definitions and properties. Each property carries its class: **V** a property of the code, proved by reading the code path named beside it and checked by the runs; **S** measured on our own models; **L** measured on real software; **P** measured by a physical meter. A V property is a statement about what the governor writes; it is not a statement that a measured outcome follows. Measured outcomes are stated with their numbers and their limits, and nothing on this page is claimed beyond them. The earlier formal results (`docs/TRACKING_THEOREM.md`, `docs/FORMAL_STATUS.md`) belong to the earlier core engine's channels and are not restated here.

20.1 Setting

A **body** is a set of plants p_1, ..., p_n run on one clock of decisions k = 0, 1, 2, ... (15 s each in the organisms). Each plant i has

- a template τ_i (compute_pool, thermal_zone, energy_storage, motion_axis, process_loop: `realms/plants.py`),
- one knob κ_i (capacity, setpoint, power or admission: the muscle's single wire),

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- a **native controller** N_i, the plant's own law, unchanged by Omni-Compass: the pod autoscaler or the cluster autoscaler of a pool, the PI loop and staging of a cooled room, the dispatch of a battery site, the servo profile of an axis, the PI loop of a process,
- a state $x_{i,k}$ and an exogenous input $w_{i,k}$ (arrivals, heat from its own load, the site's own load, disturbance), drawn from the plant's seed, the same in every arm.

The plants are coupled through the body (`realms/harness.py`, `Body.couple`): with S_k the body's source power (every plant that is neither a room nor a battery site) and Z_k the rooms' power, room z receives heat $h[z] \cdot S_{k-1}$ and battery site s receives load $g_s \cdot (S_{k-1} + Z_{k-1} -$ its nominal), where h[z] and g_s are fixed by the body's calibration.

An **override** $o_{i,k}$ is a set of key-value pairs that bounds what N_i may do at decision k: a floor and a cap on the machines a pool's autoscaler may ask for, a setpoint for a room's loop, a reserve or a defended ceiling for a battery's dispatch, a speed scale for an axis. The plant then steps by its own law under that bound: $x_{i,k+1} = f_i(x_{i,k}, N_i(x_{i,k}; o_{i,k}), w_{i,k},$ coupling_k). The empty override leaves N_i exactly as shipped.

Definition 1 (the two arms). The native arm writes $o_{i,k} = \varnothing$ for every i and k. The Omni arm writes $o_k = G(y_0, ..., y_k)$ for $k < K$, where y_k is what the governor reads at decision k and K is the decision at which the governor goes silent (in every run, K = 0.8 × the run's decisions), and the lease's walk back after K (Property V5). Both arms run the same plants, the same seeds and the same inputs.

Definition 2 (a governor, and a collection of tools). A rule G is a **collection of separate tools** if there are maps $g_1, ..., g_n$ with $o_{i,k} = g_i(y_{i,0}, ..., y_{i,k})$ for every i and k: each muscle's bound depends on that muscle's readings alone. G is **one governor over the body** if for some plant i the bound $o_{i,k}$ depends on the readings of another plant $j \neq i$.

Definition 3 (a twin). The twin T_i of a plant i is the same plant model, built from the same row and seed, fed the same exogenous input, run under N_i alone with no override. The pools' twins run inside the governor (`Bone.__init__`, `Bone.advance_twin`); a twin is the governor's model of what native does with that plant.

Definition 4 (room on a line). The lines of a body are the battery sites' connections and the rooms' cooling. For a line ℓ with distance to its limit gap_ℓ (the connection's limit plus what its battery can still clip, less its import; or a room's cooling capacity less its command, and its degrees in hand), one-decision climb up_ℓ (the larger of line_z times its step-to-step spread, the largest climb it has shown, and a prior of 5% of the line) and load per W of the body's power a_ℓ, the room over r decisions is

$R(r) = \min$ over ℓ of $(\text{gap}_\ell - \sqrt{r} \cdot \text{up}_\ell) / a_\ell$ (`Bone.room`, `Bone.room_for`),

the power the body may still add, read r decisions ahead.

20.2 What the code guarantees (class V)

Proposition 1 (V). The max is one governor over the body. In `max_body_step`, the floor written on a pool is max(now + can, base), where can is the number of machines whose idle power fits in min(R(1), R(r) − used); R reads every battery site and every room of the body, and `used` is what was granted to the pools decided before it in the same decision. So the bound on one pool depends on the readings of the body's sites, rooms and other pools: by Definition 2, the max is one governor, not a collection of tools. No set of separate tools has this property, however many run at once. ∎

Property V1 (one wire). Every override the max writes uses only its muscle's own key: {floor, cap} on a pool wired by capacity or setpoint; {setpoint} on a room wired by its setpoint; {setpoint} or {capacity} on a battery site wired by that knob; {capacity} on an axis alone (inside a body an axis keeps its everyday speed); nothing on any other muscle. Proof: every branch of `max_apply`, `max_hold` and `max_body_step` writes only these keys. ∎

Property V2 (never fewer machines than native asks for). For every pool i with a twin, at every decision k < K, the count its autoscaler is asked for is never below the twin's: a floor written is ≥ $m(T_{i,k})$, and a cap written is ≥ max($m(T_{i,k})$, n[min]), where m counts machines in service and starting. Proof: `max_ask` sets base = $m(T_{i,k})$ and want = max(forecast, base); `max_body_step` writes floor = max(now + can, base), and on a shortfall keep ≥ base. The pool's own law is a function of its own arrivals and settings only, so its twin runs exactly as the native arm's pool does: $m(T_{i,k})$ is the count native asks for at that decision. ∎

Property V3 (native at its limit is left alone). Under the max, the override of every muscle wired by power or admission, of every process loop, and of every axis whose machine has no speed above its everyday setting is empty at every decision: native already runs them at the top of their range. Proof: `max_ask` returns nothing for them and `max_body_step` writes ∅. ∎

Property V4 (grants come out of the room the lines have). At a decision with R(1) ≥ 0, the idle power of the machines the max adds, summed over the body, is at most R(1), and the machines of a pool that take r decisions to start are granted only out of R(r) less what was already granted. With R(1) < 0, what the max added goes back, the pools holding the most first, never below each pool's twin (V2), and no room is pulled below its operator's setpoint. Proof: `_units`, the running decrements of r[src], r[all] and used, and the shortfall branch of `max_body_step`. ∎ *Limit, stated with it:* R is a forecast. A line that climbs further within one decision than any climb it has shown, while power granted earlier is still in service (power is handed back one decision after a line shows the need), can still be carried over its limit. Section 20.4 gives how often that happened.

Property V5 (the lease: everything handed back). If the governor goes silent at decision K, every override moves 1/(K + W − k) of the way to its native value at each decision k ≥ K and is native from decision K + W − 1, W = 24 (`walk_back`; a floor that only held a pool at native's own count is let go at once). Every run checks every knob on every seed (`restore_ok`); a muscle or organism that fails is labelled INVALID. In the official table every muscle and every organism passed. ∎

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Property V6 (the live ranges: from 1 up to one click under the system's own capacity; amendment 5). In the live Kubernetes controller, with n the machines in service, m the floor (two), T the machine lever's top and P the ready workers: T is the operator's `--max-nodes` where given; else P plus the room the cluster's own autoscaler publishes (the sum over node groups of maxSize less registered); else, where Omni-Compass resizes the pool with the operator's command, T = f − 1 for the smallest count f the pool's command has refused, and T = ∞ before any refusal; else T = P. Every machine count written lies in [m, T], moves at most the rate limit a decision (shield I5), and cruise writes min(T, n + step). The replica cap c of a sensed service never exceeds C = max(1, ⌊(A − Q)/r⌋ − 1), A the allocatable CPU of the ready workers and of the machines the system can still add (by T), or, where every node is a container on one machine (kind), that machine's CPU once; Q the requests of every other pod and r one pod's request: one pod under what the machines hold. At the max, every pod CPU limit written is ≥ the operator's own, and no frequency ceiling or GPU limit is written below its top; on the tune-down, a CPU limit is never written under the pod's request nor its use × (1 + headroom), and a GPU limit never under the card's own minimum. Proof: `Controller._machine_room`, `_max_nodes`, `_pool_command`, `_live_ceiling`, `Muscles.push`, `_power_cap`, `_hardware` and `convey` (`omni_controller/`); `tests/test_compass_controller.py`, `tests/test_omni_controller.py`, `tests/test_muscles.py`. ∎ *Limit, stated with it:* T = ∞ refuses no count in advance: machines are still added only by the controller's own rules (the scheduling floor while pods wait for a place, one more past the compass's wall, the governor's law, cruise while a queue waits), within the rate limit; the first refusal by the pool, or by the cloud's quota behind it, sets the top from then on.

Definition 5 (the readings). For each seed s, the paired difference is d_s = Omni_s / native_s − 1 for work and energy, and Omni_s − native_s (percentage points) for the share of decisions over the line. Over n seeds, the 95% interval is mean ± t[0.975, n−1] · sd / √n. A gain or a loss is a row whose interval is clear of zero; otherwise the row reads no difference beyond the noise. Across runs A, B and C: the same sign in all three with every interval clear of zero reads "lower (or higher) in all three of our runs"; an interval across zero reads "no difference beyond the noise"; clear intervals of opposite signs read "the runs disagree" (`tools/readings.py`, `tools/confirm_abc.py`).

20.3 What the runs measure (classes S, L, P)

- **S, the muscles alone, 1,107 muscles, preregistered seeds 3000-3009, both loads** (omni-v5's run, commit `eea291501848`, digest `5648f2902f1fae68`, every muscle its own card, section 20.5; its record is `docs/OMNI_V5.md`, the no-harm proof): 527 GAIN, 421 STEADY at their limit on native (V3: the max writes nothing), 159 STEADY, no difference beyond the noise, **0 LOSS or power given, 0 mixed**. `results/realms_v5/REALMS_V5.md` now holds the run on omni-v8 of 17 October, read again by the one key on 24 October: 530 GAIN, 421 at their limit on native, 156 STEADY, the same as native, 0 LOSS.
- **S, inside the organisms, the same seeds, three loads**: every organism with fewer misses as a whole under every load, and **0 plants with less work or more misses** in every organism under every load (0 of

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

the 1,908 in the four stacked). Misses (the share of plant decisions over their line) fall 1.9% to 7.5% under each organism's own load, 1.4% to 7.2% under the climb (the load stepping 1 2 3 2 3 4 ... to twice its own) and 1.1% to 8.3% with work waiting in line, against 1.6% to 6.4%, 0.9% to 3.5% and 1.0% to 7.2% with one global setting for every muscle (digest `9be48445`, the same seeds), and the power given and the wear fall with them (`docs/OMNI_V5.md`; on the omni-v8 run, an engine that no longer stands (omni-v26 stands), Compute under its own load takes 0.01% more energy than native and 0.06% more wear, power given). Every row of that run is reported in `results/realms_v5/REALMS_V5.md`.

- **L, real software**: `docs/THE_RECEIPTS.md`, receipt by receipt.
- **P, a physical meter on a real chip**: the card's own meter on the Lambda runs (`results/gpu/`); on one A10 on omni-v23 the energy for each request served fell 0.8% to 1.8%, less energy for the same work, GAIN in all three of our runs (`results/gpu/V23_A10_CAP_FULL_ABC.md`).

20.4 The living body: why plants read LOSS, and the version that cures them (the engine since 12 October, night)

Found on development seeds only (7100-7299), never on the preregistered ones. Under the climb, rooms and UPS lines reach their limits in both arms; a plant read LOSS when the Omni arm reached a limit a moment sooner, or when a sense the brain read was wrong. Each cause, and the property of the code that removes it:

1. **A room snapped back.** A room cooled ahead of the heat, then returned at once to its operator's setpoint when the lines ran short: its own PI loop overshot warm of native, and once its cooling ran flat out the difference was frozen in. *V9 (the pedal lifted, never snapped):* a pull-down is handed back toward the operator's setpoint over the cooling's own reaction time. *V10 (no pull-down that cannot be held):* a new pull-down is granted only out of the room the lines have for that reaction time.
2. **A battery's charge counted as room after it ran out.** *V6:* a site whose battery covers its draw, but whose charge above its floor runs out within r + 1 + T decisions (T = 2: the heat of machines handed back reaches the rooms a decision later and their cooling answers over its own averaging, one more), has as room on its line only its limit less its whole draw, read at the draw's own climb.
3. **Machines handed back while a queue needed them.** *V7:* on a shortfall, a pool is never held below $\lceil(\lambda_{k-1} + Q_k / \Delta t) / \mu\rceil$.
4. **A room left warmer than native.** *V8:* every room has a twin: the same room under its operator's settings, warmed by native's heat (the body's source power with each pool's power replaced by its twin's). A room wired by its setpoint that reads warmer than its twin by e > 0 has its setpoint written at most t[set] − e, unless its cooling is already flat out.
5. **A room that cannot cure itself.** *V11 (the body cures what a muscle cannot):* a room wired by its cooling units, a power or an admission gate, or whose cooling is flat out, and that reads warmer than its twin by e > 0, puts a heat debt $e \cdot C / (\Delta t \cdot h)$ on the body (C its heat capacity, h its share of the body's source heat); the room the bone grants is bounded by minus that debt, so the machines the max added go back until no such room is warmer than native's.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

6. **A battery that never timed its discharge.** *V12:* a battery wired by its power holds its charge while its line has room after the largest climb it has shown, line_z of its wobbles and a twentieth of its limit, and gives native's full power once the line could need it; it holds nothing until it has read its line for a window of decisions (20).
7. **A lock in the senses.** *V13 (a forecast starts at the first reading):* a plant shows its initial values before its first step; the jump from them to the first reading was taken as the line's largest climb ("never forgotten") and kept every battery's timed discharge shut for the whole run. Every forecast of a line now starts at the plant's first real reading, and the bone reads nothing before the body's first step.
8. **A twin that started wrong.** The body reads its sources at their nominal power before the first step; the room twins read zero, so for the first ten or so decisions they ran up to 0.3 °C apart from native's rooms and the body cured differences that did not exist. The twins now start from the body's own reading (V8, the definition above), and with the max writing nothing every room twin equals its room to the last digit, every decision (`tests/test_compass_arm_v5.py`).

The battery's admission gate stays native: deferring a site's flexible load to keep its line clear left part of that work not caught up by the end of a run (work first).

Measured on development seeds 7100-7199, the four realms under the climb, 400 organism runs each way:

	Plants with less work or more misses	Misses (pp), the four realms	Work, the four realms
the engine before (omni-v5, 8d4f91f0)	19	−0.109, −0.125, −0.005, −0.144	+0.0013%, +0.0016%, +0.0000%, +0.0022%
V6-V10 only	7	−0.104, −0.110, −0.005, −0.137	kept
this version (V6-V13)	**0**	**−0.206, −0.187, −0.143, −0.212**	+0.0008%, +0.0010%, +0.0000%, +0.0016%

The misses fall about twice as far as before (in the Energy / Facility / Industrial body, from almost nothing to 0.14 points), and no plant in any of the 400 runs did behind native. The work gained is about two thirds of the version before: the heat debt hands back machines while a room that cannot cure itself is warmer than native's.

One lock is left, said plainly: a line that once jumped (a battery that stopped covering its site) is read as able to jump that far again for the rest of the run, which keeps the max from adding machines on that line. Removing it (every line's climb read on the site's whole draw) roughly triples the misses removed on the same seeds (−0.34 points), but in 36 of the 400 runs a machine pool whose queue sat at its limit then did more work and took one decision longer to clear it, which our decision count reads as LOSS. That is the next version's work, and it enters the engine only as a new version, every result run again on it, the founder told first.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

20.5 Every muscle its own card (the engine since 13 October)

The founder's question of 12 October, night: does every muscle have its own tuning, maxed to its own benefit, instead of one global setting for a thousand muscles? It does, and the engine now carries it.

Definition 6 (a card). For muscle i, a card θ_i is the brain's settings for that muscle: for a machine pool, its edge utilisation u_i (how full it runs on its forecast before it calls for more) and its window w_i (decisions of history it reads); for a battery, its line margin z_i (wobbles kept under its line) and, wired by its power, its hold window and hold margin. The brain is one (the same law, the same bone, the same body); only these numbers differ by muscle. A muscle without a card runs the global setting θ_0 (u = 0.95, w = 20, z = 3.09, the hold window equal to w, a hold margin of a twentieth of the line). The tune-down never reads cards.

The search (development seeds only, `tools/tune_cards.py`). Every muscle whose settings can change what the max does (458 machine pools, 44 batteries, 48 axes) tries every candidate in a declared grid on seeds 7100-7109, alone, under its own load and with work waiting in line; θ_0 is always among the candidates. Pools: $u \in \{0.70, 0.75, ..., 0.95\} \times w \in \{10, 20, 40, 60\}$; batteries wired by their power: $z \in \{0, 0.5, 1, 2, 3.09\}$ × hold window $\in \{3, 5, 10, 20\}$ × hold margin $\in \{0, 0.02, 0.05, 0.10\}$; other batteries: $z \in \{0, 0.25, ..., 4\}$; axes: heat head × strain. A candidate is kept if it beats θ_0 beyond the noise on those seeds (fewer misses, more work or faster: a 95% interval of the paired difference clear of zero), read LOSS than θ_0 nowhere, and is never behind native: on no seed and under no load over its line more often than native, doing less work or clearing its line later (the engine's own no-harm tests, seed by seed); among those, the fewest misses, then the most work, the fastest, the least energy. It is then run again against θ_0 on seeds 7200-7209 and enters the engine only if it wins there too: a card must win twice. The preregistered seeds 3000-3009 are never read by the search.

V14 (the body has the last word on a line it shares). Inside a body, a battery wired by its power keeps the body's margins on its line: its z and its hold margin are never slimmer than θ_0's; its own window stays. A card is chosen for the muscle alone, and a battery's line inside a body carries the whole body's swing, which the battery alone never saw: the one plant behind native that the cards produced in development (a rack's power allocation, one extra decision over its line in the whole tower with work waiting, one seed of ten) was exactly that case, and V14 removes it.

What the search found: 409 of the 550 searched muscles beat θ_0 on the first seeds; 364 won again on the second (45 fell back to the global setting, none LOSS); the engine's cards are those 364 (`realms/muscle_cards_v5.csv`: 333 machine pools, 31 batteries). No axis setting beat the global one. A first set of cards was chosen by the mean over the seeds alone (371 cards); the engine's own no-harm test then caught one of them (an electrolyzer battery, one decision over its line on one seed), and the rule became the seed-by-seed one above. The cards are the ones it chose. A room alone and a process loop alone have nothing for a card to fix (native almost never misses there), and the 421 knobs native already runs at their limit have nothing above native to give: their help comes from the body. Every card is printed in plain words in the muscle catalog (`docs/MUSCLE_CATALOG.md`).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Inside the six organisms, on both development sets (360 organism runs, every plant against native): 0 plants with less work or more misses, and the misses removed against native 1.7 times the global setting's over the three loads (1.2 times under each organism's own load, about 1.9 under the climb, 1.7 to 1.8 with work waiting in line):

Seeds	Own load: global → cards	The climb: global → cards	Work in line: global → cards	Plants with less work or more misses
7100-7109 (the cards chosen here)	0.078 → 0.094 points	0.153 → 0.293 points	0.088 → 0.161 points	0
7200-7209 (the cards checked here, on untouched seeds)	0.074 → 0.087 points	0.145 → 0.282 points	0.086 → 0.149 points	0

Work is unchanged within a millionth, and the power given is lower than the global setting's in the organisms where it moves at all (Compute under its own load, from 0.058% to 0.011% more energy than native's). The preregistered result, on seeds the search never read, is section 20.3.

20.6 Limits, stated plainly

- A card is chosen for its muscle alone. Inside a body the bone shares the lines and V14 keeps a battery wired by its power to the body's margins; the organisms were checked with every card on both development sets (0 plants with less work or more misses) and on the preregistered seeds (section 20.3), but a card is not tuned for the body it sits in.
- Many machine pools chose the most aggressive edge the search offered (256 of 333 cards at 0.70): their own limit may lie further out. Searching further is the next version's work, a new version with every result run again.
- V properties bound what the governor writes. They do not by themselves bound an outcome on a line the governor does not control (section 20.4).
- R is a forecast (V4). A climb no line has shown before can beat it within the one decision power takes to be handed back.
- S results are our models. They are never presented as proof of a physical saving; the physical receipt is a P run.
- The twin is exact for a pool (its law reads only its own inputs) and for a room (its heat is the body's own source reading with each pool's power replaced by its twin's, so with the max writing nothing it equals the room to the last digit); with the max writing, a room twin is native's room under native's heat as the brain reconstructs it, not a meter.

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

CHAPTER 21

The Mechanism of Action

Every statement here is tied to code in this repository, and the measured numbers are reproduced by `python tools/mechanism.py`, which writes `results/MECHANISM_OF_ACTION.json`. The engine files are frozen. Their SHA-256 hashes are checked by `verify.py`.

21.1 The state: six numbers that describe the whole system

Symbol	Name	What it stands for in a data centre
E	energy / excitation	how hard the system is being driven: queues, overload, power, heat
U	order parameter	how healthy and settled the system is: +1 healthy basin, -1 failed basin
I[U]	integrated need	unmet need accumulated over time: memory of pressure that has not been relieved
S	stress	slow structural stress from heat, power, network, security, staleness
B, Ḃ	bath and its rate	a damped oscillator driven by stress: the slow "tide" of physical load

21.2 The equations (omnicompass/core.py, lines 5-12)

```
(1) dE/dt     = −α[E] E + β[int] + β[ext] + v[eff]
(2) dU/dt     = μ U (1 − U²) − (dE/dt)/E[max] − λ[U] U + u,          |
    ↪ u| ≤ 25
(3) dI[U]/dt  = (1 − U) − σ₁ E − δ S − λ[I] I[U]
(4) v[eff]    = cos(ω[B] t / 2) · c · tanh(λ₀ + λ₁ (U − 0.5) + λ₂ S)
(5) Φ(S)      = αₛ S² / 2 + βₛ S³ / 4 − δ S

(6) dS/dt     = −dΦ/dS = δ − αₛ S − (3/4) βₛ S²
(7) dB/dt     = Ḃ ;   dḂ/dt = γ[c] δ S − (ω[B] / Q[B]) Ḃ − ω[B]² B
(8) R[B]      = finite-difference audit of (7) at every step, never fe
    ↪ d back
```

Each term does one job:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **(1) Energy.** Energy decays at rate α[E] = 3.487. It is driven by two forcings: internal pressure `β[int]` (queue and overload) and external pressure `β[ext]` (power, heat, network, staleness, security). The drive term `v[eff]` (4) is bounded by `c` through the hyperbolic tangent, so no input can drive E without limit. This is the saturation (the tanh "speed limit"): however extreme the observation, the engine's response rate is capped at c = 1.
- **(2) Order.** `μ U (1 − U²)` is a double-well (bistable) drift with two stable basins, U = +1 (healthy) and U = -1 (failed), and an unstable ridge at U = 0. A rise in energy (`dE/dt`) pushes U out of the healthy basin. `u` is the bounded control input.
- **(3) Integrated need.** I[U] grows while U is below 1 (the system is not settled). It is reduced by energy and stress already being dealt with, and it leaks at λ[I] = 0.719. It is the engine's memory of unrelieved pressure.
- **(5)-(6) Stress.** A cubic potential (the "well in the basin"). S rolls downhill to its stable root. This is the slowest restoring force.
- **(7) Bath.** A damped harmonic oscillator (natural frequency ω[B] = 1, quality Q[B] = 2.5) driven by stress. It turns stress into a smooth, lagged "tide". It is the only second-order element.
- **(8) Audit.** The bath equation is re-checked numerically every step. The check is never fed back.

Integration: classical 4th-order Runge-Kutta, 10 micro-steps of 0.01 per macro step (`rk4_step`, `macro_step`). The C++ twin matches the Python to 3.6e-15 on 500 reference trajectories.

21.3 From telemetry to state (omnicompass/adapter.py, `observe_vector`, `assimilate`)

Each decision the telemetry is normalised to nine observations: q (queue), load, power, thermal, network, drift, stale, security, conflict. An observed state is computed from them:

```
E[obs]   = 0.25 q + 0.18 max(0, load − 0.85) + 0.16 power + 0.13 therm
    ↪ al + 0.10 network + 0.08 drift + 0.06 conflict + 0.04 stale
U[obs]   = 1 − (0.27 q + 0.18 power + 0.16 thermal + 0.12 network + 0.
    ↪ 12 drift + 0.10 conflict + 0.05 stale)
S[obs]   = 0.36 thermal + 0.28 power + 0.18 network + 0.10 security +
    ↪ 0.08 stale − 0.20 q

B[obs]   = 0.52 power + 0.26 thermal + 0.22 drift
I[obs]   = q + drift + conflict
β[int] = 0.58 q + 0.42 max(0, load − 0.75)        β[ext] = 0.33 power
    ↪ + 0.27 thermal + 0.20 network + 0.12 stale + 0.08 security
```

The state is blended toward the observed state with weight a = 0.339: `x ← (1 − a) x + a x[obs]`. It is then evolved by one macro step (0.1 engine time units) of equations (1)-(7).

All patents, copyrights and trademarks filed in the USA.

Muscle	Engine quantity used	Where
Speed-first law	rho* for pods; push gates machine release	`omnicompass/speed.py`
Right-sizing	rho* sizes CPU; E widens the memory margin; push gates scale-in	`omnilab/rightsize.py`
Cold start	rho* sizes instances; I[U] sets how long to keep warm	`omnilab/coldstart.py`
GPU packing	I[U] pre-warms nodes; push gates power-off	`omnilab/gpupack.py`
Training power	E tightens the applied ramp limit under sustained grid stress	`omnilab/powersmooth.py`
GPU health	S and E shorten the checkpoint interval	`omnilab/health.py`
Cooling	E widens the inlet-temperature margin	`omnilab/cooling.py`
Inference	the full allocation law (node_delta) sizes replicas	`omnilab/inference.py`
Agent containment	I[U] throttles; the security observation contains	`omnilab/containment.py`
VM energy	I[U] and E raise the learning rate when attribution goes stale	`omnilab/vmenergy.py`

21.6 Measured: what the equations actually do inside the governor

Measured on a real observation stream (fleet plant, web services, fleet mode, 360 decisions):

Mode (eigenvalue of the Jacobian at the operating point)	Time constant	In decisions
-7.90	0.13	1.3
-3.10	0.32	3.2
-0.72	1.39	13.9
-0.20 +/- 0.98i (the bath)	5.0, period 6.4	50, rings every 64 decisions
-0.17	6.0	60

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Every mode is stable** (all real parts negative). The operating point is a stable equilibrium inside the healthy basin: E = 0.095, U = 0.976, S = 0.315, B = 0.10. This is the basin keeping everything in, stated as mathematics.
- **Per decision, the equations and the observation move the state about equally.** Across all six variables the equations contribute 45-50% of each step's movement and the observation blend the rest.
- **Equation (2)'s control input u is not applied during governance.** The engine evolves open-loop (u = 0). The control law is evaluated only to produce `push`, which decides when capacity may be released.
- **Compute:** about 95 microseconds per decision in Python, and about 2.9 microseconds in the C++ twin.

21.7 What this explains, and what it points to

- **Why "engine off" scores close to "engine on" in the muscle benchmarks.** With the equations frozen, the observation blend still moves the state. Both versions are then low-pass filters of the same telemetry. The engine's fast modes (1-3 decisions) behave almost like the blend itself. Its distinct contribution is its slow memory: I[U] (14 decisions), S (60) and the bath (period 64 decisions). The muscle mappings mostly read E and rho*, which live on the fast modes.
- **The engine clock is not matched to the workload's rhythm.** One decision advances engine time by 0.1. At 60-second decisions the bath rings every 64 minutes, but web demand has a 24-hour rhythm and training power a 2-second one. This is a wiring choice in the adapter (engine time per decision), not a property of the equations.
- **The controller in equation (2) is unused as an actuator.** Wiring its output u (or U's trajectory under u) directly to the actuators is the unexplored way to "let the math do the work".

Three wiring experiments follow directly. None changes a single equation:

1. **Clock matching.** Set engine time per decision so that the bath's natural period equals the workload's rhythm. The oscillator in (7) then carries the cycle and can anticipate it.
2. **Slow-mode actuation.** Drive machines from I[U], S and B (the memory modes) rather than E (a fast mode).
3. **Closed-loop actuation.** Apply equation (2)'s u and use its magnitude, not only its sign, as the actuator command.

Each is testable in the existing harness against every platform in the league (tuning/league.py), and will be tested there.

21.8 One pedal: push, lift off, idle, reset, and the kill switch

Omni-Compass drives a system the way a self-driving car drives itself: it feels, gauges and adjusts, with nobody in the seat. The words below are used the same way everywhere in this repository.

Two names only. native is the system as it runs on its own (Kubernetes and its autoscalers, the card's firmware, CityLearn's controller). **omni** is Omni-Compass on top of native: the same native system, with

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Omni-Compass governing it. Omni-Compass never runs instead of native, only on top of it, so every comparison is native against omni.

The modes. Off (manual): Omni-Compass not driving, native runs alone. Watching: Omni-Compass reads every gauge and logs what it would do, and writes nothing. Autopilot: the one pedal below. Cruise and idle at once: for work that comes as a pile.

Term	Meaning	In the code
Push	Traffic climbs and capacity is added at once, never held back; the whole cluster can take work the instant it is needed	(8.3); a lower HPA target is never limited
Lift off	Traffic falls and capacity is eased off a step at a time, handed back toward native, never below idle	(8.4)-(8.5); coasting, rule 6
Idle	The pedal lifted all the way: calm traffic, the engine running at its floor (two machines in service, ready)	`MIN_NODES`, the floor of the staging law (8.8)
Reset	Every setting the governor ever wrote is handed back to where native had it, read back, and the record removed; the next run starts fresh. Every benchmark arm ends with one and checks it	the reset file (`--kill-file`, a name kept for compatibility), `Controller.restore`
Cruise	A pile of work waiting for a place: machines in service up to the pool's own top, read live (a fixed pool's every machine at once, a growing pool a step a decision), held there without second-guessing, until the line has been empty for two decisions	rule 7, `--cruise-after`
Idle at once	The work is done and demand is at zero (the service at its least pods, wanting no more, at half its target or less): the pedal lifted all the way in one move, straight to idle (the floor), every safety check still holding	rule 8, `--idle-demand`, amendment 9
Kill switch	Security only: one switch in a human hand that turns Omni-Compass's governing off across the whole system at once, for anything rogue or anyone trying to drive a system through Omni-Compass's brain	`omnicompass/master.py`, `tools/omni_switch.py off`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The floor is a number the operator sets; lifting off never takes the system below it, however far the pedal is lifted. Earlier dated records, and the sealed original engine files, call the reset a "kill switch"; they are kept word for word.

21.9 The staging law: machines on and off in order, with demand that moves

Demand climbs, spikes, eases part way, climbs again and settles to idle. The staging law decides how many machines are in service at every decision, and which ones, so that capacity follows demand up at once and comes back down only as far as it safely can. It is the compass law (`omnicompass/compass_law.py`) applied to the machine pool (`omni_controller/controller.py`), the release gate (`omnicompass/nervous_system.py node_release_gate`), the verdict (`omnicompass/verdict.py`) and the actuator (`scripts/kind_nodepool.sh`). Every symbol below is a line of that code.

Position and force. The service reading r (the 95th-percentile response time, or the pressure that stands for it) is placed in its band [lo, hi], where hi is the response line:

```
p = (r - lo) / (hi - lo),      v = s v + (1 - s) (p - p_prev) / dt
    ↪                    (8.1)
F = A                                      if p >= 1 - c        (fail
    ↪  up, past the wall)
F = A tanh( (kp (p - p0) + kd v) / A )     otherwise; F = 0 if F < 0
    ↪ while v > 0 and p > p0   (8.2)
```

with the band's center p0 = 0.5, cushion c = 0.05, authority A = 1, kp = 1 and kd = max(0, 2 sqrt(kp tau / dt) - 1) dt (critical damping for a muscle that answers in tau seconds). F > 0 asks for capacity, F < 0 offers it back.

How many machines. With n machines in service now, n[nat] the count native ran, m the floor (two by default, `MIN_NODES`) and M the machines that exist (every machine usable; an operator may hold whole machines back with `NODE_CUSHION`, off by default), every count stays in m <= n' <= M. The protection is not a machine sitting out: it is the band inside every machine. Capacity is added at 95% of the response line, before the line is reached (8.2-8.3), and a machine goes back only if the ones left still run at or under the engine's utilisation target rho (8.5): a margin spread over all of them.

```
up      n' = min(M, max(m, n + 1))                                 if p >
    ↪ = 1 - c                    (8.3)
down    n' = max(m, n - 1)                                         if F <
    ↪  R and p < p0 and the verdict
                                                                   allows
    ↪  n_nat - (n - 1) and the gate G holds  (8.4)
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
hold    n' = n                                                    otherw
    ↪ ise
```

with the release threshold R = -0.2. Up is immediate and is never gated. Down is one machine per decision, never below the floor, and only when every term of the release gate holds:

```
G = [n > 1] and [nothing pending] and [pods not scaling up] and [no br
    ↪ each now] and
    [ used / ((n - 1) x per_node) <= rho ] and [contraction authority]
    ↪  and [every sense live] and
    [the last machine command landed]
    ↪                          (8.5)
```

rho is the engine's utilisation target: after a machine goes back, what remains runs at or under rho. The verdict (section 21.7 of the GPU preregistration, `omnicompass/verdict.py`) allows a machine count below native only after a paired trial showed the service at that count at most a 2% LOSS than at the count before; that 2% is where the trigger sits, inside the engine.

This is hysteresis by construction. The up condition (p >= 0.95) and the down condition (p < 0.5 with F < -0.2) are far apart, so a demand that hovers never makes machines flap; a spike crosses the wall and adds a machine at once; a dip has to be deep, calm and sustained before one goes back, and then only one per decision. Between the two, the count holds.

Which machines. The actuator orders the pool:

```
idle   the open machine with the fewest serving pods, then the fewest
    ↪ pods, goes first;
       it is marked prefer-not (PreferNoSchedule) and its pods first t
    ↪ o go (pod-deletion-cost), so the
       autoscaler's own scale-down empties whole machines; no pod is m
    ↪ oved, evicted or restarted   (8.6)

wake   the idle machine still carrying the most work goes first (it is
    ↪  warm); the mark comes off and it is in
       service at once, with no boot
    ↪                         (8.7)
floor  two machines always in service (MIN_NODES, the operator may set
    ↪  more), ready for a spike  (8.8)

margin  every machine usable; the cushion is the band inside each one
    ↪ (the 5% before the line, and rho), not a
        whole machine held out
    ↪                         (8.9)
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

An idled machine stays powered and Ready at its floor (park_frac x idle power), never off: a pod that finds the open machines full lands on it at once, so no request ever waits on a machine Omni-Compass idled. Where a node autoscaler underneath really removes an empty machine (Azure's cluster autoscaler, Karpenter), that same order hands it the emptiest machine first, and the bill falls with the machine.

The same law on every discrete unit. Machines are one case. In the muscle models (`realms/compass_arm.py release_safe`), a cooling plant's chillers and a compute pool's machines follow the same law: one unit back only when the units left cover the recent peak with headroom (RELEASE_MARGIN 0.6 for machines, 0.8 of a unit's capacity for chillers), one at a time, and back at once when the wall is reached.

What is proved, measured and open. The order (8.6)-(8.8) is checked through the real actuator by `tests/test_staging_order.py` (the emptiest idles first, the warmest wakes first, two always in service, every machine usable, no pod moved). The gate (8.5) is checked by `tests/test_node_release_gate.py`. On real Kubernetes, in the single-run sets 22 to 27 of September (an engine before omni-v1, `results/live/LIVE_REPS_22.md` to `results/live/LIVE_REPS_27.md`: the road, never read with the engine that stands), the law gave the same work with the 95th percentile down 53% to 65% and the machines in service down 29% to 37%. On omni-v25 (`results/OMNI_INDEX.md`; omni-v26, the engine that stands, runs it again), all four in one run reads the work up 43.5% on the same machines (machines STEADY, the same), demand that wanders is `results/live/V25_WANDERING.md`, and, composed across every layer, the machines read ×0.5626: Omni-Compass's 1.78 times native's, power given (`results/WHOLE_SYSTEM.md`, section 3). Open: an order across different kinds of unit (a battery before a generator, a CPU before a GPU) is not wired; each pool is ordered within itself.

21.10 The state each muscle carries, and the modes as a state machine

9.1 The compass on a muscle is a dynamical system, so its state must persist. On muscle i the compass carries $z_i = (p_i, v_i, x_i)$: the position of the service in its band, its velocity, and the knob's continuous value. At each decision k, with reading r_k:

$$p_k = (r_k - lo) / (hi - lo), \quad v_k = s\, v_{k-1} + (1 - s)(p_k - p_{k-1}) / dt, \quad F_k = F(p_k, v_k) \text{ by (8.2)} \qquad (9.1)$$

$$x_{k+1} = \text{clamp}(x_k + \text{sigma}\, g(F_k)\, F_k\, (x[hi] - x[lo]),\ x[lo],\ x[hi]), \quad g = \text{UP if } F_k > 0 \text{ else DOWN} \qquad (9.2)$$

with x_0 the native value and sigma = +1 when a higher value is more capacity. Two properties depend on z persisting: (a) the knob integrates the force, $x_k - x_0 = \text{sum}_j \text{ sigma } g\, F_j$ span (until the cover binds), so a calm muscle eases step by step toward its cover; and (b) the damping term kd v_k needs p_{k-1}. If z were made fresh at every decision ($p_{k-1} = p_k$, v = 0, $x_k = x_0$), (9.2) would collapse to $x_{k+1} = \text{clamp}(x_0 + \text{sigma } g\, F(p_k, 0)\ \text{span})$: a memoryless map of the present reading, at most one step from native, with no damping. That is a different,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

weaker law. A renamed attribute did exactly that on 2026-10-05; `tests/test_compass_arm.py` now fails if the compass is ever made twice on one muscle.

9.2 The modes. The live controller is in exactly one mode at each decision. With q_k the pods waiting for a place, u_k the scaling-up flag, c the cruise count (`--cruise-after`, 2), M the machine ceiling and m the floor:

```
cruise on      q_j > 0 for the last c decisions
    ↪                              (9.3)
cruise off     q_j = 0 and not u_j for the last c decisions
    ↪                              (9.4)
in cruise      n' = min(M, n + s), M the pool's own top read live, s t
    ↪ he step; the service's autoscaler target held at the operator's
    ↪ own; the floor step
               makes no read and no write
    ↪                              (9.5)
idle at once   (not cruising) q = 0, no breach, not u, every sensed se
    ↪ rvice idle or at demand
               <= b, the gate G (8.5) holds, every sense live, the las
    ↪ t command landed:
               n' = max(m, smallest n carrying the CPU in use at rho)
    ↪                              (9.6)
idle (a service at its floor)   I(h) := current = min = desired, and u
    ↪ _h <= target_h / 2           (9.7)
push / lift off / idle         (8.3) / (8.4)-(8.5) / (8.8)
```

9.3 Why cruise steps back (9.5). In cruise the machines climb to the pool's own top (a fixed pool's every machine at once, n = M; a growing pool a step a decision), so the floor step's only action (raise n to the floor the waiting pods need) adds nothing the climb does not already give: for a fixed pool floor <= M = n. Its reads (every pod, every node, node metrics, every HPA, each five seconds) carry no value of information, so removing them cannot change any action; they only cost CPU and API-server time on the machines the queue is using. The service's response time is also confounded in cruise: with a queue of other work holding the machines, a request waits on contended CPU, R = S / (1 - u[host]), not on the service's own pods. Reading that R as the service's own queue and adding pods would answer the wrong cause. So in cruise Omni holds the machines and leaves the service to its own autoscaler. `tests/test_compass_controller.py` checks that the floor step makes no API read during cruise; the controller before this rule made the full set of reads every five seconds.

9.4 Why idle is read from the autoscaler's floor (9.7). A served service never reads zero: a health probe or a client's keep-alive keeps one pod at a few percent of its request. In the batch test, one pod at about 10% of its

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

request read as demand 0.10, above b = 0.05, and idle waited 15 minutes after the queue emptied. The autoscaler's own floor is the observable of "no demand beyond the minimum": the pods it keeps are its minimum, it wants no more, and they run under half the target. In the five frozen-engine web tests the service was never at its floor (0 of 5,102 readings), so (9.7) changes nothing there.

9.5 Reporting resolution. A paired change smaller than one part in a million of the value (|mean difference| <= 1e-6 |native|) is read "same", the number still shown. Below that, a difference is rounding in floating point and in the models' accumulators, not behaviour; a deterministic run gives a zero-width interval around it, which would otherwise read as proven.

9.6 A lever is moved only where moving it can pay. The compass decides how far and how fast. Whether a lever may move at all is a property of the muscle's physics. Four cases, each derived from the muscle's own model and each its own test:

- *Cooling power.* A zone's heat must leave it: over a run, the heat removed equals the heat made plus what the room's mass stores. A cap on cooling power q[max] cannot remove less heat. It only lets the temperature drift above setpoint while the PI command grows, and the staging rule, units = ceil(command / (0.8 q[unit])), turns that command into more units and more fan power, p = q[c] / COP + units x p[unit]. So a lower cap never saves energy, and the lever stays native. (The setpoint, which changes the COP, and the units, which change fan power at the same heat, remain levers.)
- *A battery's reserve.* Energy D drawn from the cells below the operator's reserve saves D sqrt(eta) of grid import, and the deficit is bought back at D / sqrt(eta). The net, D (1 - eta) / sqrt(eta) (10.5% of D at eta = 0.90), is always positive. Spending the reserve is never an energy saving; it is the price of keeping the draw under the connection's limit. So the reserve is spent only at the wall (p >= 0.95) and only when the battery can cover the excess (0 < imp - p[lim] <= p[batt]). Otherwise the operator's reserve holds, and no round trip is paid for nothing.
- *A backup reserve (a UPS).* It is held for an outage, which the model does not contain, so spending it for a peak trades away the reason it exists. Never a lever.
- *A compute pool's power cap.* With throughput mu(c) proportional to c^eps and the autoscaler holding utilisation near its target u*, the energy per unit of work is e(c) = (p[idle] / u* + p[dyn] c) / mu(c). At c = 1, de/dc > 0 (a lower cap saves) if and only if

```
eps < p_dyn / (p_idle / u* + p_dyn)
  ↪                                   (9.8)
```

At eps = 0.4 the cap saves on CPU hosts (threshold 0.62), GPUs (0.74), databases (0.51) and radio units (0.54). It costs energy where idle power dominates: a quantum computer's cryostat (0.19), a network switch (0.32), storage (0.26). There, running slower keeps the machines on longer: race to idle. In a deployment p[idle], p[dyn] and the speed curve come from the machine's own specification.

- *A motion axis's effort cap.* It lowers the copper loss of a full-acceleration move, (J a[max] / kt)^2 R, and stretches the move, which keeps paying the standing draw p[idle] + b v[max]^2. It moves only where the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

first exceeds the second: a reaction wheel (32 W against 5 W), not EV traction, a flight axis or a robot joint.

- *A machine released from a node pool.* A machine boots in minutes, and a burst that arrives in the meantime is served late. So a machine goes back only when the machines left cover the recent peak at 0.3 of the pool's own release level, the largest margin at which no pool is later than native (`results/realms/RELEASE_MARGIN_SWEEP.md`). This is the verdict of the live controller (section 21.9) in model form.

What a lever buys is labelled for what it is. Less work per energy, with no work lost and the time over the line proven lower, is SERVICE IMPROVEMENT WITH ENERGY TRADEOFF, the mirror of ENERGY IMPROVEMENT WITH SERVICE TRADEOFF. Without that proof it reads LESS WORK PER ENERGY.

CHAPTER 22

The Safety Case: Every Hazard, Its Guard, and the Evidence

Omni-Compass writes settings that a native controller would otherwise own. A referee's first question is what happens when it is wrong, is attacked, or dies. This page answers it hazard by hazard. Each row names the guard in the code that stands against the hazard and the evidence that the guard holds: a test that runs on every push (`python3 verify.py`), or a measured run (evidence class L). Where no evidence exists yet, the row says so. The page adds no mechanism; it maps the mechanisms that are already there. Section 22.3 is the plug's interface, as the code defines it.

22.1 The claim this page supports

Do no harm (its meaning, `DISCLOSURES.md` section 3): the organism Omni-Compass governs is never left turning out less than its native controllers make it turn out, nor less healthy (no muscle past its own limit, no service over its own line, nothing made to fail). On the engine that stands, that means: Omni-Compass never leaves a setting other than native's after it stops, never acts on a reading it cannot trust, never takes a step that a paired trial on the system itself showed costs more, never exceeds a bound the system or its operator set, and can be switched off by one human action, everywhere at once.

22.2 Hazards, guards and evidence

#	Hazard	Guard (where it lives)	Evidence that it holds
H1	The governor dies, hangs or loses its machine, leaving a	Before its first write, every governor records the exact	`tests/test_master_switch.py`; the robustness kill test

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Hazard	Guard (where it lives)	Evidence that it holds
	setting changed	commands that put every setting back, and renews a lease every decision. A watchdog finds any governor whose process is gone or whose lease is stale and runs those commands for it (`omnicompass/master.py`: `register`, `heartbeat`, `orphans`; `tools/omni_switch.py`: `watchdog`, `reclaim`)	(the governor killed outright mid-run, every setting back within the allowance in every repetition; `docs/ROBUSTNESS_PREREGISTRATION.md`); `tests/test_robust.py`, `tests/test_robust_restart.py`
H2	Someone takes over the governor, or it behaves in a way nobody intended	The kill switch: one file, one command. Every governor sees it at its next decision, writes back every setting it changed, reads each one back and exits. A governor that cannot read the switch treats that as OFF (`omnicompass/master.py`, `tools/omni_switch.py off`)	`tests/test_master_switch.py`
H3	A write is refused or silently fails, so the governor's belief and the system differ	Every write goes through the plug, which reads the value back (`omnicompass/muscle_sdk.py`: `execute`, then `readback`, then a receipt). At the end of every run the reset is read back against the snapshot, and the run fails if any record is left (`scripts/kind_bench.sh`)	`tests/test_muscle_sdk.py`; every three-run table prints "handed back to native's and read back at the end of every omni arm in every run: yes"
H4	It gives back too much, so service breaks when load returns	Floors read live: never below one replica, a pool never below two machines. A machine is given back only after its own trial shows the response time holds, and it wakes at once on a	`tests/test_node_release_gate.py`; the fault test (`results/live/V7_FAULTS.md`)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Hazard	Guard (where it lives)	Evidence that it holds
		breach (`omni_controller/controller.py`)	
H5	On a shared host, one tenant's raise starves the others	No CPU limit is raised while the host is 75% busy or its reading is missing; conveyance stays inside each namespace's CPU quota, and an unreadable quota means no known budget, so Kubernetes admission decides (`omni_controller/capacity.py`, `omni_controller/quota.py`)	`tests/test_capacity.py`, `tests/test_kind_capacity.py`, `tests/test_quota_convey.py`; the noisy-neighbour test (`results/live/V7_FAIRNESS.md`, STEADY)
H6	It acts on a reading it cannot trust	A reading with no machine in service is blind: the decision holds, says why, and writes nothing (omni-v11, `omni_controller/controller.py`). A muscle whose reading is stale reports BLIND, and no command is executed (`omnicompass/muscle_sdk.py`: `MuscleStatus`)	`tests/test_blind_reading.py` (the fault reproduced on omni-v10, gone on omni-v11); `results/model_gate/V11_VS_V10.md`; the extended fault test, the API server frozen and the metrics server gone (queued, A, B and C: `docs/K8S_COMPASS_PREREGISTRATION.md`)
H7	It keeps a step that hurts the system	One trial at a time, on the system itself: a reference phase at the deepest step already allowed, then one notch further. The step is refused if its median cost exceeds the reference's by more than 2%, or the cost first measured at the operator's setting. Refused steps wait 60 s; a trial is abandoned if the service swings (`tools/knob_verdict.py`)	`tests/test_knob_verdict.py`, `tests/test_verdict.py`, `tests/test_verdict_interval.py`; every database table prints each trial's count, allowance and refusal

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Hazard	Guard (where it lives)	Evidence that it holds
H8	It writes outside what the operator allows	A capability contract (minimum, maximum, resolution, step and rate limits) and a safety contract (hard bounds, forbidden contexts, fail closed) on every muscle (`omnicompass/muscle_sdk.py`: `CapabilityContract`, `SafetyContract`)	`tests/test_muscle_sdk.py`
H9	It uses more privilege than its job needs	Least-privilege service account (`deploy/kind/rbac-omni.yaml`), and every arm records what it can and cannot do (`kubectl auth can-i`, `rbac_omni.txt` in each run's folder)	The receipts in every run folder on the branch `raw`
H10	It expands while a security hold is on	The shield: no expansion during a security hold (invariant I1), with a C++ twin checked against the Python (`omnicompass/shield.py`, `cpp/`)	`tests/test_shield_properties.py`, `tests/test_cpp_shield_parity.py`, `tests/test_cpp_shield_adversarial.py`
H11	In the cloud, it raises the bill for the same work	The bill is judged, never ruled (the founder's order of 31 October struck the machines-alone rule of 14 October): every cloud set reads the bill beside the work it bought by the one key, the cloud's judged number the work per dollar: a factory tune whose work per dollar falls against native (a bigger bill for the same work) is not admissible (`docs/THE_TUNE.md`) and is a fault of the tune, root-caused in the model first; the machine lever asks the cloud for no	Azure: no difference in the bill on the engine of 13 October, at the tune-down on the machines alone (`results/live/AKS_BILL.md`); the sets at the max carry the work meter from 31 October, night, a tuning case first, so each reads the work per dollar. Google and Amazon: **undetermined**, not yet run.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Hazard	Guard (where it lives)	Evidence that it holds
		machine (`scripts/kind_nodepool.sh`); paid sets capped at 100 repetitions and 1, 10 and 100 copies	
H12	A test machine's limit is reported as the governor's effect	Paired arms on the same runner, rotated order, the refusal rules for an unhealthy window, and the kind rig's image pre-puller (`docs/POD_START_WAIT.md`). `tools/confirm_abc.py` marks any table whose runs differ in engine or rig	`tests/test_confirm_abc.py`, `tests/test_pod_phases.py`, `tests/test_release_campaign.py`
H13	The hand-back itself is turned against the system: a record another local user planted makes the watchdog run a command or stop a process, or a governor's pid given to another process gets that process stopped	The watchdog acts only on records of its own user that no other user can write, read without following a link; a pid counts as the governor's only while its process started before the governor registered (`tools/omni_switch.py`, 18 October). Every threat of misuse is set out in `docs/THREAT_MODEL.md`	`tests/test_switch_trust.py` (each fault reproduced on the tool as it stood, gone on the fix)

22.3 The plug, as the code defines it

Every muscle is reached through one interface (`omnicompass/muscle_sdk.py`, `MuscleAdapter`). The sequence is fixed: observe, bound, request, execute, read back, receipt, restore.

Call	What it must do
`observe()`	Return the muscle's reading with its timestamp; a reading older than its timing contract makes the muscle BLIND
`snapshot_native()`	Capture native's setting once, before the first write; this is what every restore returns to
`execute(value)`	Write one value, already clamped by the capability contract and permitted by the safety contract

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Call	What it must do
`readback()`	Read the value the system actually holds; a mismatch is recorded, never assumed away
`restore_native(snapshot)`	Put native's setting back, then read it back

Each muscle carries three contracts: timing (observation and decision periods, actuation delay, the age after which a reading is stale, the minimum hold and cool-down between writes), capability (range, resolution, step and rate limits, reversible, read back) and safety (hard bounds, forbidden contexts, fail closed, a safe default). A muscle built on the SDK cannot be declared without all three. It starts in recommend mode and writes only when set to automatic or approved from outside; every command, written or refused, leaves a receipt with the reason, the reading's age, the value asked, the value bounded, the value the system holds and the difference between the last two (`MuscleRuntime.command`).

22.4 What this case does not yet cover

- **No outside security review or penetration test.** H2, H9, H10 and H13 rest on our own tests; the threats still open are listed in `docs/THREAT_MODEL.md`, section 3.
- **No formal proof of the whole controller.** The theorems in `docs/TRACKING_THEOREM.md` hold for the compass law's channel; global stability of the full six-state system is open (`docs/FORMAL_STATUS.md`).
- **No production deployment.** Every hazard above is exercised on our own rigs (kind on GitHub runners, Azure's managed Kubernetes, the database servers in our workflows), not on a customer's system.
- **Physical plants.** The GPU's power and clock guards and every facility muscle are exercised only in our models or a stand-in card until the chip runs exist (undetermined).

CHAPTER 23

The Threat Model: Misuse, Its Guards, and What Is Open

The safety case (`docs/SAFETY_CASE.md`) asks what happens when the governor is wrong or dies. This page asks what happens when someone wants it to do harm. It names what is worth protecting, where trust changes hands, each threat with the guard in the code that stands against it and the test that shows the guard holds, and what is still open. It is our own analysis: **no outside security review or penetration test has been made**, and nothing here stands in for one.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

23.1 What is worth protecting

Asset	Why it matters
The settings the governor writes (replicas, the autoscaler's target, a node's idle mark, a CPU limit, a power cap, a database pool)	Whoever controls them controls the service's capacity
The governor's identity on the system (on Kubernetes its service account and token)	It carries every right the governor has
The hand-back: the snapshot of native's settings, the registry of restore commands, the switch file	They put the system back when the governor stops; whoever can write them chooses what "back" means
The engine's code (the 65 fingerprinted files of omni-v26, the engine that stands) and the harness that measures it	A changed engine is a different product; a changed harness is a different result
The audit lines and the raw receipts	They are the evidence for every result and every decision
The cloud and GPU credentials (GitHub secrets)	They spend money and create machines

23.2 Where trust changes hands

1. **The operator and Omni-Compass.** The operator starts Omni-Compass, grants its rights and sets its bounds; Omni-Compass is trusted to act only inside them.
2. **Omni-Compass's host.** Omni-Compass, the switch and the watchdog run as processes of one user on one machine (a pod, a runner or a server). Every other local user is outside that boundary.
3. **Omni-Compass and the system it supervises.** It reads through the system's API (Kubernetes, `nvidia-smi`, a database's own commands) and writes through the same API with a least-privilege identity. The readings are inputs it does not control.
4. **The repository and the machines that run it.** Code reaches a run through GitHub: a pushed commit, an action, a Python package. Secrets reach a run only through GitHub's secret store.

23.3 Threats, guards and evidence

#	Threat	Guard (where it lives)	Evidence	Still open
T1	Another local user plants a record in the watchdog's registry, so the watchdog runs that	The watchdog acts only on a record that it and the registry directory are owned by its own	`tests/test_switch_trust.py` (a record anyone can write, a registry anyone	A member of the governors' own group can still write a record the governors' umask

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Threat	Guard (where it lives)	Evidence	Still open
	user's command, or stops a process, with its own rights	user (or root, or a uid named with `--trust-uid`), that is no symbolic link and that no other user can write. Each record is opened inside the directory without following a link and checked on the open file, so nothing can be swapped in between. Any other is refused, named, and left in place (`tools/omni_switch.py`: `trusted_records`, 18 October)	can write, a record reached through a link, a record of another user: each refused; each fault reproduced on the tool as it stood)	leaves group-writable
T2	An Omni-Compass process dies, the system gives its process number to another process, and the watchdog takes that process for the dead one, hung, and kills it	A process number is taken for Omni-Compass's only while the process holding it started before Omni-Compass registered (`governor_alive`, from `/proc`); otherwise the process is gone, nothing is signalled, and its settings are handed back (18 October)	`tests/test_switch_trust.py` (the watchdog as it stood killed the process holding the number; now it hands back and the process lives); `tests/test_master_switch.py` (a hung Omni-Compass process is still stopped and handed back)	Systems without `/proc` keep the old reading
T3	A link planted at the switch file's path makes `off` overwrite another file	The switch file is opened without following a link; if it cannot be written, every	`tests/test_switch_trust.py` (the file the link points at is left as it was)	—

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Threat	Guard (where it lives)	Evidence	Still open
		governor is still signalled and the tool says so (`tools/omni_switch.py off`, 18 October)		
T4	Anyone who can write the switch's directory, or an Omni-Compass process's own kill file, turns Omni-Compass off, or keeps it off	Off is the safe direction: every setting goes back to native's (the kill switch's purpose). `status` warns when the switch's or the registry's directory can be written by another user	`tests/test_switch_trust.py` (the warning)	The default directory is `/tmp/omni-compass`, written in `omnicompass/master.py`, an engine file; until the next engine version moves it, set `OMNI_MASTER_OFF` and `OMNI_REGISTRY` to a directory only the governors' user can write. The cloud install keeps it inside the pod, where every container runs as one user (10001)
T5	The governor's identity is stolen	Least privilege: on Kubernetes the service account can read nodes, pods, metrics, autoscalers and workloads cluster-wide; patch nodes and evict pods (the eviction API honours disruption budgets); and, in the service's namespace, patch the one named autoscaler and Deployment, pods (their deletion cost and	The receipts in every run folder on the branch `raw`	The rights it has are enough to cordon and drain nodes; whoever holds the token is limited by the role, not by the governor's floors

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Threat	Guard (where it lives)	Evidence	Still open
		in-place resize) and Jobs, and read one named ConfigMap. It cannot delete an object directly, create a workload or read a Secret (`deploy/kind/rbac-omni.yaml`). Every arm records what the identity can and cannot do (`kubectl auth can-i`, `rbac_omni.txt`)		
T6	Someone feeds the governor false readings (a lying metric, a stalled probe)	A reading with no machine in service holds the decision and writes nothing (omni-v11); a stale reading makes a muscle BLIND (`omnicompass/muscle_sdk.py`); every step is a paired trial on the system itself, refused if its cost rises more than 2% (`tools/knob_verdict.py`, `omnicompass/verdict.py`); every write stays inside the capability and safety contracts	`tests/test_blind_reading.py`, `tests/test_muscle_sdk.py`, `tests/test_knob_verdict.py`; the fault test's blind probe; the extended fault test's frozen API server and missing metrics server (queued)	A false reading that stays consistent and inside the bounds can steer the governor within the room the operator granted
T7	The engine's code is changed	The engine is fingerprinted: `OMNI_V25.json` names the digest of its	`tests/` (the release manifest and the version tool); every run's receipt names the	Releases are not signed artefacts, the repository's bots commit unsigned, and

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Threat	Guard (where it lives)	Evidence	Still open
		65 files, and `python3 tools/omni_version.py` names the engine a checkout carries, or what differs from every fingerprint. `python3 verify.py` holds every place that names the engine to the engine that stands (`tools/land_engine.py --check`)	engine its commit carries	nothing checks the fingerprint when Omni-Compass starts
T8	A dependency is replaced (a Python package, a GitHub action)	Every package pip installs is pinned to an exact version with the SHA-256 of every file PyPI publishes for it (`requirements-lock.txt`, hash-checking mode), with a software bill of materials (`sbom/omni-compass.cdx.json`, `sbom/omni-compass.spdx.json`, written by `tools/sbom.py`); every action a workflow uses is named by its commit, its tag beside it (407 uses, 19 October); `security-scan.yml` audits every pin against the public vulnerability databases each week; Dependabot watches	`tests/test_supply_chain.py` fails a push with an action named by tag or a package without hashes; `tools/sbom.py --check` in `verify.py`	Closed for what Omni-Compass installs; the tools a benchmark machine installs from its own package manager (kind, kubectl, the databases) are pinned by version, not by hash

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Threat	Guard (where it lives)	Evidence	Still open
		both the packages and the actions (`.github/dependabot.yml`)		
T9	A secret leaks from a workflow	Secrets reach only workflows started on this repository (a push or a dispatch); no workflow runs on `pull_request_target`, so no fork's code ever runs with them. Secrets are kept in GitHub's store only, and GitHub masks them in every log. A key stored in another form is named by its shape before any cloud's login step reads it, never a character of it printed (`tools/cloud_key_check.py`), because a login step's own refusal can quote the first characters of what it was given, and a piece of a secret is not masked (21 October: Azure's did, on a public run page)	Every workflow names its token's rights; `tests/test_cloud_check.py` fails a push that leaves any Azure login without the shape check before it; the 28 that only build, run and upload get `contents: read` and nothing else (18 October). `tests/test_workflow_permissions.py` fails a push that leaves any workflow on the repository's default, or gives a read-only token to a workflow that pushes, starts a run or reads another run's files	—
T10	A run spends money it should not	In a cloud the whole engine runs at the max (the founder's order of 31 October) on top of the cloud's own autoscaler, which alone adds machines; the	`results/live/AKS_BILL.md`; `tests/test_cloud_check.py`	The credentials in the secrets can create clusters; their scope is set in each cloud's console

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Threat	Guard (where it lives)	Evidence	Still open
		governor's lever parks a machine that exists and wakes it, and asks the cloud for none (`scripts/kind_nodepool.sh`); the bill is judged beside the work it bought, a tune whose work per dollar falls against native not admissible (`docs/THE_TUNE.md`), and paid sets stay at 100 repetitions and 1, 10 and 100 copies. A cloud's set starts only after that cloud's $0 check passes (Google, Amazon and, since 22 October, Azure: the key, the login, the plan, the machine type, every quota; `tools/cloud_key_check.py`). Nothing is rented for the grid		
T11	The evidence is changed after the run	Every archived run is kept byte for byte on the branch `raw` with its SHA-256 sums (`scripts/raw_archive.sh`); every table names its runs and is rebuilt by its own tool from them	`tests/test_raw_archive.py`	Audit lines are not signed when written; the sums protect them from the moment they are archived

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Threat	Guard (where it lives)	Evidence	Still open
T12	The system's control plane is taken away (the API server frozen, the metrics server gone)	The governor holds on a reading it cannot make; a failed decision writes nothing; its lease runs 300 s at a 60-second decision, so a short outage does not hand back what is working	The extended fault test (queued, A, B and C: `docs/K8S_COMPASS_PREREGISTRATION.md`)	Whatever the runs read is reported

23.4 What would close the open rows

- An outside security review and a penetration test of the governor, the switch and the install.
- In the next engine version, the switch and the registry in a private directory by default, created with no access for any other user (T1, T4).
- Release artefacts signed, and the fingerprint checked when a governor starts (T7).

CHAPTER 24

The Static Security Scan, Every Finding Reviewed

Generated by `python3 tools/security_scan.py` (Bandit, the Python security linter of PyCQA) over every Python file that runs (`omni_controller/`, `omnicompass/`, `realms/`, `tools/`, `scripts/`, `fleet/`, `k8s_controlplane/`; 54,023 lines). The workflow `security-scan.yml` runs it on every push to main that touches code, and every week, with `pip-audit` over every pinned dependency; it fails on a finding of high or medium severity that no review below names.

1 finding of high severity and 40 of medium severity, every one reviewed below; 418 of low severity, counted by kind. Fixed on 19 October: a world-writable PgBouncer folder (now owned by postgres, 0o755) and the MD5 that PostgreSQL's own password method defines, now marked as not used for security. Fixed in omni-v14 (21 October): the operator's own commands (the site power reading, a muscle's read command, a wall meter's) run without a shell unless they hold a pipe, a redirect or a variable, so the governor's site power reading no longer reaches a shell at all and one high finding is gone. Fixed on 3 November: the wall meter's

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

command (`tools/wall_meter.py`, `cmd:`) runs without a shell at all, a pipe included (each stage's output into the next), and anything else only a shell reads is refused with the reason, so a second high finding is gone.

24.1 Every finding of high or medium severity, and why it stands

Check	File	Severity	Findings (lines)	Why it stands
B103 (Chmod setting a permissive mask 0o755 on file (dir))	`tools/run_pgbench.py`	medium	1 (390)	PgBouncer's folder on the benchmark machine is owned by postgres and set 0o755: others may read and enter it, never write it
B108 (Probable insecure usage of temp file/directory)	`k8s_controlplane/mechanism_harness.py`	medium	1 (166)	a path on the benchmark's own throwaway machine (a GitHub runner), never on a machine Omni-Compass governs
B108 (Probable insecure usage of temp file/directory)	`omni_controller/controller.py`	medium	1 (1620)	a default file name for the audit log in the working folder, not /tmp; the operator sets --audit
B108 (Probable insecure usage of temp file/directory)	`omni_controller/gpu_compass.py`	medium	1 (394)	a default file name for the audit log, as above
B108 (Probable insecure usage of temp file/directory)	`omni_controller/gpu_governor.py`	medium	1 (475)	a default file name for the audit log, as above
B108 (Probable insecure usage of temp file/directory)	`omnicompass/master.py`	medium	1 (44)	the switch's registry folder under the operator's runtime folder; the watchdog trusts only its own registry (docs/THREAT_MODEL.md, T4)
B108 (Probable insecure usage of temp file/directory)	`scripts/dispatch_grid.py`	medium	1 (440)	a path on the benchmark's own throwaway machine (a GitHub runner), never on a machine Omni-Compass governs

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

Check	File	Severity	Findings (lines)	Why it stands
B108 (Probable insecure usage of temp file/directory)	`tools/gpu_actuator_watchdog.py`	medium	1 (65)	a path on the benchmark's own throwaway machine (a GitHub runner), never on a machine Omni-Compass governs
B108 (Probable insecure usage of temp file/directory)	`tools/omni_control.py`	medium	1 (550)	the control panel's default kill file, under /tmp/omni-compass on the operator's own machine, where the panel and the governor it starts run as one user; the operator sets it with --kill-file or OMNI_CONTROL_KILL_FILE, and the governor reads only the file the panel hands it (docs/CONTROL_PLANE.md)
B108 (Probable insecure usage of temp file/directory)	`tools/run_kafka.py`	medium	4 (819, 819, 824, 826)	a path on the benchmark's own throwaway machine (a GitHub runner), never on a machine Omni-Compass governs
B108 (Probable insecure usage of temp file/directory)	`tools/run_redis.py`	medium	2 (612, 614)	a path on the benchmark's own throwaway machine (a GitHub runner), never on a machine Omni-Compass governs
B310 (Audit url open for permitted schemes. Allowing use of file:/ or custom schemes is often unexpected)	`omni_controller/controller.py`	medium	1 (201)	every URL it opens is an https address written in the code or the operator's own endpoint, never one read from data (the operator's metrics endpoint)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Check	File	Severity	Findings (lines)	Why it stands
B310 (Audit url open for permitted schemes. Allowing use of file:/ or custom schemes is often unexpected)	`scripts/aks_kubectl.py`	medium	1 (33)	every URL it opens is an https address written in the code or the operator's own endpoint, never one read from data

24.2 Findings of low severity, by kind

Kind	Findings
B603 subprocess_without_shell_equals_true	179
B404 blacklist	87
B607 start_process_with_partial_path	70
B101 assert_used	52
B311 blacklist	17
B110 try_except_pass	6
B105 hardcoded_password_string	3
B606 start_process_with_no_shell	2
B107 hardcoded_password_default	1
B112 try_except_continue	1

The low-severity kinds are the patterns of a harness that drives other programs: a subprocess started with a list of arguments and no shell (B603, B607), the subprocess module imported (B404), an assert in a test helper (B101), a pseudo-random number for a modelled load (B311), and the throwaway passwords of the benchmark's own local databases (B105, B107).

CHAPTER 25

Every Dependency and Its License

Generated by `python3 tools/sbom.py` from `requirements-lock.txt` (Omni-Compass 0.26.0); `tools/sbom.py --check`, run by `verify.py`, fails a push where this page or the bill of materials (`sbom/omni-compass.cdx.json`, CycloneDX 1.5; `sbom/omni-compass.spdx.json`, SPDX 2.3) is not what the lock gives, where a pinned package has no license read, or where a license is strong copyleft. Every package is pinned with the SHA-256 of every file PyPI publishes for its version, and `security-scan.yml` audits every pin against the public vulnerability databases each week.

29 packages; every license permissive except one weak, file-level copyleft (MPL-2.0, Hypothesis, used by the tests alone and never shipped with the engine); no GPL, LGPL or AGPL. Each package keeps its own license; nothing in the Omni-Compass Evaluation License changes those terms (`THIRD_PARTY_NOTICES.md`).

CHAPTER 26

The Engine That Stands: Omni v26

Omni v26 (`OMNI_V26.json`, digest `75d3c22eed4473b9`, 65 files) is omni-v25 with one fault fixed in the Kubernetes governor (`omni_controller/controller.py`). Do no harm keeps its strictest form. On the founder's standing order that every fault found is fixed and lands as the next version, told, not asked, and his order of 6 November ("Just get everything else push, and push").

26.1 The fault

Read from the omni-v25 runs' own files (`docs/LOSS_CAUSES_2026-11-06.md`). On the batch rigs a batch queue shares the cluster with the web service, and its pods wait, on and off, as its normal queueing. While the web service is past its line, the governor's decision chooses between the cover's floor for its autoscaler target (30%, more pods: the fail-up) and native's own target (50%): the fail-up only while no pod in the cluster waits, native's target otherwise. The count of waiting pods is the whole cluster's by design, since a pod of any workload waiting means the room is spoken for and Omni-Compass's extra pods may not hold it.

The rule that keeps native's target while pods wait is the immune hand-back's hold (omni-v19: ten minutes, doubled for each hold in a row). Only the fast check started it, and only while the target still stood below native's. The decision had already put the target back at native's by then, so the hold almost never started, and the next decision that found no pod waiting failed up again. On the KAI scheduler's four ways the target

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

flipped 304 times over 30 repetitions, and the hold caught on 21 times. Kubernetes' autoscaler takes a lower target at once and a higher one only after its five-minute window, so the flips kept extra web pods in room the queue was owed: in the 15 repetitions where the queue ran long, it finished 0.1% to 6.8% later, and the web service's minutes at 1 to 5 s lasted as long. On every batch rig read, the more the target flipped, the larger the web service's rise.

26.2 What changes

- When the decision returns a service's target to native's because pods wait while the target stood below native's, and some of the waiting pods are another workload's, it starts the hand-back's hold itself (`_hold_for_waiting`), on the hand-back's own clock. The fail-up is then not taken again while the hold runs.
- Another workload's waiting pods (`_others_waiting`): every Pending pod that is not one of the service's own (its scale target's selector) and not a DaemonSet's. A DaemonSet's pod belongs to its node: it waits for a machine that is joining, never for another workload's room, so a machine being added never starts the hold. Where the selector cannot be read, every other waiting pod counts.
- Where only the service's own new pods wait (a machine still coming for them), the decision keeps omni-v25's rule unchanged.
- The snapshot hands its pod list on (`snapshot`, `pods`), so the rule reads the pods the decision already read: no extra list.

26.3 The tests and the model gate

`tests/test_neighbour_hold.py`: a web service past its line beside a batch queue whose pods wait on and off, through the governor's whole decision on the stand-in cluster. omni-v25 writes the target 30, 50, 30, 50, 30; omni-v26 writes 30, 50 and holds. A new machine's DaemonSet pod never starts the hold, another governed service's waiting pods keep omni-v25's rule, and so do the service's own.

The model gate against omni-v25 (`results/model_gate/V26_VS_V25.md`, class S, our own models; `tools/model_gate.py`, seeds 1 to 8): all twelve models identical to omni-v25 on every gauge and every seed, 104 readings and none different, so no LOSS against omni-v25. In them the decision's new branch never fires: in the cloud and on-site cluster models every waiting pod belongs to a service an autoscaler governs, and the conveyance, card and verdict models never reach the decision.

A first form of the change counted another governed service's waiting pods as well. The gate refused it: in the cloud model at a decision every 15 s the 95th percentile read up 2.7%, beyond the seeds' noise, and at 60 s the pods waiting up 0.8% by the mean, because one service's new pods waiting for a machine started the hold for another. That form is not in omni-v26; the form that stands leaves another governed service to its own rule, the fast check's hand-back of omni-v19. A DaemonSet's pod, which waits for a machine that is joining, never starts the hold either (a refinement written before the gate's final run, held by its own test).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The batch queue's replay (`results/model_gate/V26_BATCH_FLIP.md`, class S, `tools/batch_flip_model.py`): the native arm's own timelines of the KAI scheduler's four ways (30 repetitions: the cluster's waiting pods and the web service's 95th percentile), replayed open loop through both governors at the factory beat on site. The writes of the web service's target fell from 16.13 to 2.67 a repetition (GAIN, down 83.5%), the changes of the target after the first from 15.20 to 1.73 (GAIN, down 88.6%), and the seconds the target stood below native's while another workload's pods waited from 22.17 to 4.83 (GAIN, down 78.2%); the holds started rose from 0.03 to 1.43 (power given: the hold is the fix itself). Open loop, it reads the decision rule alone; the service's and the queue's own gauges are read only by the benchmarks' runs.

26.4 What is run again

Every benchmark runs again on omni-v26 from 14:31 UTC on 7 November 2026 (`scripts/reruns.txt`, A of every entry, then B, then C; the conductor's campaign, `scripts/dispatch_grid.py`). The omni-v25 runs started before that moment run to their end as omni-v25's record; nothing is cancelled.

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

CHAPTER 27

The Engines and Their Audit

27.1 Which engine is which

There is **one** engine. Every other engine-looking file in this repository is either its required C++ twin or a frozen copy of where it came from. Nothing else runs.

File	Role	Runs?
`omnicompass/core.py`	**The engine** (`symmetric_verified`): six states, eight lines, RK4 with microsteps. Everything Omni does goes through it.	yes
`cpp/src/core.cpp`, `cpp/include/omnicompass/core.hpp`	The same engine in C++. Required: `verify.py` checks it against the Python on every fixture.	yes (twin)
`docs/handoff/mathematics/omni_compass_engine_source_c527df2d.py`	The original source as handed over (sha256 `c527df2d…`). Kept unchanged as proof of origin and as the parameter authority.	no (frozen)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

File	Role	Runs?
`reference/omni_compass_reference_engine.py`	The same original with comments stripped (`tools/strip_reference.py`); same program fingerprint (`reference/PROVENANCE.json`).	no (frozen)

Fingerprints of the running engine, its parts and its twin: `results/MECHANISM_IDENTITY.json` and `RELEASE_MANIFEST.json`. `verify.py` fails if any of them changes without a new seal.

27.1.1 Engines from outside packages, not adopted

Copies of this repository passed around as zips (the XPASS packages) carry changes that are **not** in the engine here:

- `batch_claim1.py` (in those zips, not in this tree): a vectorised variant that applies u during the RK4 step (CLAIM1). No C++ twin; not verified against the 500 fixtures.
- an adapter that defaults to CLAIM1, takes the target sign from the starting state and adds a disruption budget. Its C++ governor was only partly ported, which is where the reported Python/C++ mismatches came from.

None of these enter before the GPU counted run (the engine is frozen for it, `docs/GPU_PREREGISTRATION.md`). Any of them can be adopted afterwards only as a full change: Python and C++ together, the parity tests and `verify.py` green, and a new mechanism id.

27.1.2 The rule from here

One engine, one twin, two frozen originals. A new version **replaces** the old one in place, with a new seal; it is never added beside it. Older states are in git history and `docs/HISTORY.md`, not in extra files.

27.2 My engine, line by line: the source against what runs in your cluster

The source. `docs/handoff/mathematics/omni_compass_engine_source_c527df2d.py` (SHA-256 c527df2d…, 31,348 lines). Every mechanism below is named by its function there, followed by where it runs live and how it is checked on every `python verify.py`.

Mechanism	In the source	Where it runs	Checked by	Status
Six states E, U, I_U, S, B, Ḃ and equations (1)–(7)	`oc_derivatives`, `rk4_step`	`omnicompass/core.py`	`tests/test_core_parity.py`: 20,000 random states, max difference ≤ 1e-12	exact

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Mechanism	In the source	Where it runs	Checked by	Status
Spinor closure, 720°: drive × cos(½ ω_B t)	`v_eff`, `spinor_closure_factor`	`core.v_eff`	same parity test	exact
Axle rest S* from equation (6)	`stable_S_equilibrium`	`omnicompass/storage.py`, `compass.axle`	parity; `tests/test_compass.py`	exact
Double well W(U), basins ±1	`W_potential`, `W_gradient_flow`	`core.derivatives`	parity	exact
Regulation u = −f_U + K_P(σ − U), clipped at the authority	`hybrid_microstep_operator`	`core.control_command`; the governor's push	parity; 500 frozen trajectories (`fixtures/`), 0 mismatches	exact
Basin lock, conveyance, certification	`run_monte_carlo`, `macro_step`	`core.simulate`	500 frozen trajectories, 0 mismatches	exact
Composite storage V = V_U + V_W + V_E + V_S + V_I + V_B, the ledger that closes the circle	`composite_practical_lyapunov_value`, `bath_lyapunov_matrix`, weights	`omnicompass/storage.py`, read by the compass every decision	parity on 5,000 states (≤ 1e-13); descends 648 → 8 over 60 regulated steps with no rise	exact
Human switch: a file or a variable stops every command	`_oc_runtime_stop_requested`	`--kill-file`, restore of every lever	`tests/test_failsafe.py`, `tests/test_muscles.py`, every live run's switch drill	exact
Mechanism	**In the source**	**Where it runs**	**Checked by**	**Status**
Cap doctrine C1: only a ceiling *above* the reference is admissible; a lower one buys energy by slowing work	`_ci_omni_decision`, certificate C1–C4	`muscles.convey`: CPU limit never below the operator's, idle CPU conveyed to the work	`tests/test_convey.py`	exact

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Mechanism	In the source	Where it runs	Checked by	Status
Sleep only in a certified empty interval	`_ci_omni_decision`, sleep channel	`scripts/kind_nodepool.sh`: a machine idles only once its work has left	`tests/test_active_nodes.py`, `tests/test_convey.py`	exact
Reference Kubernetes HPA rule	`oc_hpa_desired_replicas`	`cpp/` HPA, pod reflex	`tests/test_cpp_hpa_parity.py`	exact

27.2.1 Where my live wiring reads the engine differently from the source's own embodiment

Evolution between decisions. The source's compute embodiment advances the assimilated state *with* regulation locked on basin +1. My live governor advances it with u = 0 and reads the regulation command separately, as the push that gates every machine release.

- Both use the same equations.
- The difference is whether the regulation is applied to the state or only read from it.
- The pre-registered, frozen results were measured with u = 0. I keep that setting, and I report the difference here rather than change a frozen law mid-measurement.

CHAPTER 28

Change Control: How the Engine Changes

The engine is the set of files whose bytes decide what Omni-Compass does: the brain, the compass law, the verdict, the live governors, the harness the models run in, and the wires that fasten the brain to an outside simulator. Their SHA-256 digests together make the engine's fingerprint (the engine that stands, `OMNI_V26.json`: 65 files, digest `75d3c22eed4473b9`). `python3 tools/omni_version.py` reads the tree and names the engine it holds, or says which file differs from every declared engine.

28.1 The rules

1. **Any change to a rule, a gain, a guard, a preset or a muscle makes the next version.** No engine file changes inside a version. A fix to a fault found in the engine is the next version, never a patch to the one that stands.
2. **Every change goes through the model gate first** (`tools/model_gate.py`, `results/model_gate/`): the shipped controller on the model cluster in the cloud setting, conveyance

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

on one kind host set to a real run's own regime, the verdict on noisy work, the same seeds, paired against the engine that stands. A LOSS there is root-caused and fixed in the model; a change that reads no LOSS and shows promise goes to its GitHub trials; nothing is dispatched before.

3. **A version lands in one command**, `python3 tools/land_engine.py vN --since <UTC>`: the fingerprint, the version list, the conductor's campaign (`scripts/reruns.txt`), the grid's manifest and workflows, the package version (0.N.0), the root list and a release group. `tools/land_engine.py --check`, run by `verify.py`, refuses a push in which any of those places still names an older engine.
4. **Every benchmark runs again on the new version**, A, B and C, released by the conductor in a fixed order; a run is counted on the engine its own commit carries, read from GitHub at its head commit.
5. **No result is read across versions.** A three-run table is one engine's three runs (the table tools refuse to call runs on two engines one table); an older table stays its own engine's record, in `results/live/` until each benchmark's three runs on the new version land, then the newest table is the one shown.
6. **Every fix lands as the next version, and the founder is told.** A change that reads no LOSS in the model gate lands at once as the next version (the founder's order of 19 October, night: "Of course I want you to land version 12 ... every time you do that ... it becomes a new version"); he is told what it changes, why and what it read, and is not asked whether to land it. A change that reads a LOSS anywhere is root-caused and fixed in the model first and never lands as it stands.

28.2 The record

Version	Landed (UTC)	Digest	Files	What changed, and why
omni-v5	11 Oct 22:40	`6093b2b88aa911b9`	44	the max as the default brain on the 1,107-muscle catalog; re-declared while in development
omni-v6	15 Oct 06:18	`df6147466ef18046`	45	shared-host capacity: on kind the host's processor counted once
omni-v7	15 Oct 15:25	`d6d467b824c585f1`	46	conveyance bounded by the namespace's CPU quota; every rule in seconds
omni-v8	17 Oct 15:39	`f93d233136a1f902`	46	CityLearn: a battery whose building has outages stays native (its charge is the building's reserve)
omni-v9	17 Oct 22:21	`7379f3a79ff2c475`	47	CityLearn: the battery wire reads the coming hour; the exact Student t
omni-v10	18 Oct 04:23	`4bf39b0d707784de`	47	CityLearn: the battery glide that cuts the bill most with no LOSS
omni-v11	18 Oct 16:03	`745aa53ec8eeb67b`	47	Kubernetes: a reading with no machine in service is held, never read as an overload

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Version	Landed (UTC)	Digest	Files	What changed, and why
omni-v12	20 Oct 00:30	`d38b58fbe28939b8`	47	Kubernetes: a raise the cluster's admission refused is held, not written again at every check; the swarm's proximity reflex at once (its wire outside the digest, declared with the version)
omni-v13	20 Oct 20:31	`0088837333c6f0fc`	47	Kubernetes: the CPU limits the conveyance gave go back to the operator's on a shared host at its top beside another workload's room; every other pod counted by its own limit
omni-v14	21 Oct 04:47	`7afba44615fcff8f`	47	Kubernetes: a knob that leaves any one muscle native; the operator's own commands run without a shell
omni-v15	22 Oct 02:30	`0a53cdd7a558f803`	55	the brain: the power cap's request trims only while the response line has been clean for the governor's own clear time (the omni-v11 long run's 126 switches in 350 decisions); every wire that holds a governor's rules in the fingerprint (eight taken in, their bytes as they stood)
omni-v16	22 Oct 07:30	`5c5502f12b1c0ce4`	55	the Kubernetes governor: every clock in seconds (the brain's minute and its C++ twin, the compass's damping and smoothing, the edge, the additions past the floor, a command's minute to land, the host's busy share, the heat law, one batch job a minute, the conveyance every 15 s, the loop's own schedule), so the decision period is a clean setting; the heartbeat, the full decision, every 15 s by default (the founder's word, "15 sec all over"), the fast checks every 5 s; at 60 s exactly omni-v15's decisions; the pace read by its own runs (`docs/PACE_PREREGISTRATION.md`)
omni-v17	23 Oct 17:00	`7c937d09e4031cc7`	55	the Kubernetes governor's heartbeat a dial, the main engine every 60 s (the parser's default; omni-v16's was 15 s), any beat from 5 to 120 s, every beat shown beside native (`results/model_gate/V17_LADDER.md`, the live engine page's 1j); the monitors scale with the beat (`omni_heartbeat_seconds`, the alert at three beats, the panel's `/v1/beat`); the cruise wait never under two readings (at 90 and 120 s it had rounded to one, found by the dial's own ladder before it landed); the

Version	Landed (UTC)	Digest	Files	What changed, and why
				founder's order of 22 October, afternoon
omni-v18	24 Oct 02:51	`1cb92edb64c4391d`	62	Omni direct taken into the engine: the seven rule files of Omni-Compass's own orchestrator fingerprinted, the three arms shown together (`docs/OMNI_V18.md`)
omni-v19	24 Oct 16:54	`36ee67284c035235`	62	the pod muscle of its own (`--own-replicas`) for a workload no autoscaler governs; the models' arm by itself (`docs/OMNI_V19.md`)
omni-v20	25 Oct 13:24	`1df07f8e36a97985`	62	the five data stores' wires fixed at their causes (sysbench's own statements, Kafka's hand-back within a poll round, YCSB's cache growing back while it misses) (`docs/OMNI_V20.md`)
omni-v21	25 Oct 17:30	`b658f05d43c1e602`	63	the immune system knows itself, knob by knob: a knob redlining past its line that Omni-Compass cannot bring back goes to native when native's twin reads it lower (`docs/OMNI_V21.md`)
omni-v22	30 Oct 18:30	`0e23a0bc561b900a`	65	the five data stores' wires at the max, through each store's own account of a miss; the governor's hand-back tried five times against a transient failure of the cluster's API (`docs/OMNI_V22.md`)
omni-v23	31 Oct 20:00	`c96ea4105d8747db`	65	Omni direct keeps every muscle Omni-Compass cannot be: a workload's own scale write the cluster refuses three times in a row hands the knob back to native's own pod autoscaler, made from the operator's target and range (the founder's order of 31 October; `docs/OMNI_V23.md`)
omni-v24	2 Nov 01:30	`66c8f2d94b3e4725`	65	the factory beat for its place: with no beat set, the Kubernetes governor reads the cluster's nodes at its start and decides every 10 s on site and every 60 s through a cloud (a reading that fails keeps 60 s, a beat set by hand always wins), the pick of a rule frozen before any reading (docs/PACE_PREREGISTRATION.md, amendments 4 to 6); the model gate against omni-v23: no LOSS; eleven of twelve models identical; on site the minutes over the line down 60.7% and the 95th percentile down 8.2% (GAIN)

Version	Landed (UTC)	Digest	Files	What changed, and why
omni-v25	3 Nov 21:00	`cf56fc0a7b707452`	65	the Kafka wire's producer started before the governor's thread: from omni-v22 the forked producer inherited a lock that thread held and never sent a message, so every Kafka run on GitHub stopped at the job's 150-minute limit; a producer that overruns its schedule now stops its workload with the reason; the governor's decisions byte for byte omni-v24's (`docs/OMNI_V25.md`)
omni-v26	7 Nov 14:31	`75d3c22eed4473b9`	65	another workload's waiting pods hold native's target: when a service's target stood below native's and pods waited, the decision returned native's target without starting the immune hand-back's hold, so a batch queue's normal waiting flipped the web service's target every one or two decisions and the flips kept extra web pods in room the queue was owed; the decision now starts the hold when the waiting pods include a workload's no autoscaler governs (`docs/OMNI_V26.md`; the model gate identical on all 104 readings, no LOSS)

Each version through omni-v15 was a fault found in a real run and fixed, omni-v16 made the decision pace a clean setting and set the heartbeat at 15 s on the founder's word, and omni-v17 made the heartbeat a dial with the main engine at 60 s on his word the same afternoon; each version since, omni-v18 to omni-v25, is the row above it in the table: the record is in `docs/OMNI_V6.md` to `docs/OMNI_V25.md`, and each model gate's reading in `results/model_gate/`. Twelve versions in twelve days is the cost of fixing every fault the day it is found (the founder's order of 18 October: every fault fixed, none set aside); the rules above are what keep that pace from mixing results.

28.3 What stability means here

A version is stable for a benchmark when its three runs on that version have landed with no change in between. omni-v25 has stood since 3 November 21:00 UTC, when its campaign opened; its three-run tables go into `results/live/V25_*.md` as they land. Every older engine's tables stay its own record under its own name (`results/live/V<n>_*.md`), never read as omni-v25's. The engine's proofs (`docs/ENGINE_PROOFS.md`), its coverage (`docs/ENGINE_COVERAGE.md`) and its reproducibility check (`tools/reproduce.py`) are run on every push, so a version that stands is also a version that is re-proved, re-tested and re-built from its receipts each time anything else changes.

28.4 Gaps this page names

- Up to omni-v14 the fingerprint held three of the outside-simulator wires (`tools/run_citylearn.py`, `tools/run_pandapower.py`, `tools/run_kil.py`); the other wires that hold a governor's rules (the data stores' `tools/run_redis.py`, `run_kafka.py`, `run_pgbench.py`, `run_sysbench.py`, `run_ycsb.py`, and `tools/run_swarm.py`, `run_mujoco.py`, `run_cpu_power.py`) were versioned by git and tested, but a change to them did not move the digest. Closed in omni-v15 (21 October): every one of them is in the scope (`tools/omni_version.py`, 55 files), and a version declared before them is read without those eight wires and only those: any other file its list does not name still makes the tree a different engine.
- A wire outside the fingerprint carried a fault: the swarm's proximity reflex (`tools/run_swarm.py`) slowed a drone over a second where its own comment says at once, and on a mission draw outside the preregistered seeds it let drones collide (`results/model_gate/V12_SWARM_REFLEX.md`). Its fix is a change to a guard, so by rule 1 it was a version, not a patch: it landed as part of omni-v12 and is declared in `docs/OMNI_V12.md`, although the file's bytes do not move the digest; a swarm table counts only on a commit that carries it.

28.5 The next version's list

Each change below was found in a real run or in our own reading of the code, and each has its evidence written down. Each goes through the model gate against the engine that stands and, when it reads no LOSS there, lands at once as the next version with `tools/land_engine.py`; the founder is told what it changed (rule 6). Landed in omni-v25, under the standing order that every fault found is fixed: the Kafka wire's producer started before the governor's thread, so the runs that had stopped at the job's limit since 30 October hand in their files again (`docs/OMNI_V25.md`); in omni-v24, on the founder's orders of 23 and 31 October and his word of 1 November: the factory beat for its place, 10 s on site and 60 s through a cloud, the pick of the pace preregistration's frozen rule (`docs/OMNI_V24.md`); in omni-v23, on the founder's order of 31 October: a knob whose own-scale writes the cluster refuses handed back to native's own autoscaler, so the organism never runs with a knob nobody moves (`docs/OMNI_V23.md`); in omni-v17, on the founder's word of 22 October, afternoon: the heartbeat a dial, the main engine every 60 s, every beat shown beside native (`docs/OMNI_V17.md`); in omni-v16, on his word that morning: every clock of the Kubernetes governor in seconds, the decision pace a clean setting, the heartbeat every 15 s (`docs/OMNI_V16.md`); in omni-v15, from this list: the power cap's request through the line's own clear time, every wire in the fingerprint, and the kill test's 300 s reading declared (`docs/OMNI_V15.md`; a dwell with a glide was refused by the gate and is not in it); in omni-v14: the operator's commands without a shell, beside the founder's knob for every muscle; refused there by the gate and kept on the branch `v14-convey-study`: no conveyance raise on a reading that leaves out another workload's starting pods (`docs/OMNI_V14.md`, section 3); in omni-v13: the conveyance's hand-back on a shared host at its top, found on KubeRay's rig (`docs/OMNI_V13.md`); in omni-v12, from this list: the refused raise held and the swarm's reflex at once

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(`docs/OMNI_V12.md`). The kind rig's governor role still does not read the namespace's quotas, a grant the Operator's Manual, section 5.5, makes optional, so the omni-v12 capacity runs read the hold in the real cluster.

Change	Why	Evidence so far
The Redis harness's brain in its own process, as a deployment runs it	the brain thread shares the load generator's interpreter lock	`docs/TAIL_LATENCY.md`, section 4
The verdict keeps a step only when the upper end of every 95% interval of its change in cost is inside the allowance (`omnicompass/verdict.py`), its reference measured long enough, from its own spread, to show a free step within the allowance; a trial that could not be read in its time is never started	today a step is kept when its estimated cost is within the 2% allowance even if the interval reaches past it: at the noise measured on the omni-v10 tables (the spread of the log response time 0.43 to 0.46), a give-back that truly costs 3% is kept about 31% of the time, 5% about 15% (found by the live-engine session, 19 October)	89 kept steps on the omni-v10 data-store tables had an interval reaching past 2%, none read LOSS in a table. The strict form was built and read in the model gate (branch `v12-verdict-study`): on work fast enough to read a step (200 pieces a decision) a free step was kept 98% of the time against omni-v11's 66%, a 3% step 0% against 26%; but on the model cluster set from a real run's regime (about 80 requests a decision, about 4,000 needed a phase) no give-back trial started and the governor read identical to native, the machine-hour cut gone, and on the data stores (one sample a second, 40 to 120 a phase; 432 to 23,430 needed, read from the omni-v11 audits) every knob would stay native. Refused as written; the row stays open until a trial design that reads a 2% step in a trial's time is shown in the model gate
The Kubernetes governor counting a worker an add-on marks while it serves, and keeping its clock under load	the CruiseKube runs of 18 and 19 October	the recorder's fix of 19 October (`CHANGELOG.md`)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Change	Why	Evidence so far
The governor's other costs on a saturated shared host	one saturated KubeRay repetition with no raise during its queue still read +4.0% on the batch pods' hashing; the governor's decisions (every 60 s then and again from omni-v17, every 15 s on omni-v16) and their reads run on cores the kind nodes share through the control plane	one repetition is not a reading: the omni-v13 runs of the batch rig read it, pod by pod, before any change
The pods that wait for a place, in the cloud's setting and in the kind benchmark's	in the model's cloud setting (the tune-down, machines alone) the pods wait for a woken machine longer than native's at every decision pace, the old 60 s default included: pending pod minutes an hour native 8.2, every 60 s 20.9, every 15, 10 and 5 s 18.4, 15.9 and 16.5: more pods waiting, LOSS against native at every pace (up 95% to 155%); the omni-v15 gate read the same row at 15 s up 111.7%, LOSS; in the kind benchmark's setting (the compass law at the max) about four times native's at every pace (32.0 at 60 s, 33.5 at 15 s, 28.8 and 28.6 at 10 and 5 s)	`results/model_gate/V16_PACE.md`, `results/model_gate/V16_VS_V15.md` (cluster15); the real cloud sets' pod start waits to be read beside it when their tables land
The cloud setting's small cost in response time and alert minutes	in the model's cloud setting (the tune-down, machines alone), against native, read by the one key: at 15 s the 95th percentile up 0.47% on the 5 s plant and up 0.36% on the gate's 15 s plant (STEADY, under the 0.5% floor) and the alert minutes up 2.31% on the 5 s plant (LOSS, more minutes over the line); at 60 s the 95th	`results/model_gate/V16_PACE.md`, `results/model_gate/V16_VS_V15.md` (cluster15, cluster_shipped, cluster_blink); the cloud sets' alert minutes are a judged row of every receipt

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

Change	Why	Evidence so far
	percentile up 0.49% on the 5 s plant (STEADY) and up 0.63% on the gate's plant (LOSS), the alert minutes up 1.85% (LOSS); against 60 s each reads STEADY, so the engine's, not the pace's; the blink model's alert minutes read up 2.35% against native at 60 s (LOSS) in the gates from omni-v13 on (on omni-v25's gate they read GAIN, the row below)	
The model's web model brought to the batch rig's 3-core host from a real run's files	in `convey_batch` both engines read 2% to 3% fewer requests served than native, with no batch at all as well, while KubeRay's real runs read 4% more after the queue; the same model reads the alert minutes 9.8% and the job turnaround 0.05% above native's (LOSS) in every gate since omni-v13's	`results/model_gate/V13_VS_V12.md` to `V17_VS_V16.md`; the regime to be set from the KubeRay runs' own after-queue files before the model is read for that gauge
The pod start wait in the convey models	against native the pods start 8.99% slower, 10.0% at the 95th percentile (LOSS), in every gate since omni-v8's, while the host serves 64% more requests at a 53% lower 95th percentile; omni-v7's page wrote it as the price of the busier host's work, but a wait that rose is a LOSS by the key	`results/model_gate/V8_VS_V7.md` to `V17_VS_V16.md` (convey, convey_unreadable_quota); the KEDA real runs' start wait, read with the rig's pre-puller (`docs/POD_START_WAIT.md`)
The card models' 95th percentile	on the modelled card the 95th percentile reads 2.38% above native's where the voltage falls with the clock and 5.78% near the voltage floor (LOSS), in every gate since omni-v15's, where the	`results/model_gate/V15_VS_V14.md` to `V17_VS_V16.md` (card, card_floor); the GPU runs on Lambda read the real card

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Change	Why	Evidence so far
	models were added; the 99th percentile STEADY, the card's energy 4.7% and 1.3% lower (GAIN), the limit written 17 and 35 times a run	
The brain's dwell and its wait after an addition at the fast beats	omni-v16 restated both in seconds (at 15 s, 4 and 20 steps for the 1 and 5 a minute); the live-engine session (branch `main`, 22 October) reports on its own sweep, on-site at 5, 10 and 15 s, machine-hours up 3.8%, 3.4% and 2.9% against native (more machines put in, power given) where a build counting them as readings that agree read from down 1.0% to up 0.9%, the pods waiting the same; the main engine's 60 s is untouched by it	not yet reproduced here; a search of the dwell counted in readings at each beat, in the tune study's rule (`docs/THE_TUNE.md`, section 4)
The cloud's floor check and a warm reserve	the same session reports two faults under `--give-back-only`: a floor that orders machines the cloud has already deleted is read as a command that did not land and holds every give-back, and give-backs made before the largest requests of the last hours are read leave too few machines; with both fixed its build read identical to native in the cloud setting at every beat, where the engine that stands reads the pods waiting, the 95th percentile and the alert minutes LOSS at some beats	not yet reproduced here; candidates for the cloud setting's LOSS rows (the rows above), through the model gate

Read again on omni-v25 (4 November; the model gate `results/model_gate/V25_VS_V24.md`, class S). Three rows above were read on older settings and stand corrected here, and six open items named on other pages join the list:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Change	Why	Evidence so far
The pods that wait for a place, at the max (the cloud's setting from 31 October)	against native, native's 7.311 pending pod-minutes an hour against 8.247 at the main engine's 60 s and 11.565 at 15 s: up 12.80% and 58.18%, LOSS; the row above reads the struck tune-down	`results/model_gate/V25_VS_V24.md`, the cluster models
The card's 99th percentile	against native, up 0.94% on the modelled card and 4.59% near the voltage floor, LOSS (the row above reads it STEADY)	`results/model_gate/V25_VS_V24.md`, `card` and `card_floor`
The blink model's alert minutes	now GAIN against native, down 22.54% (26.625 to 20.625 minutes over the line, fewer minutes a person is paged): the LOSS the cloud-cost row names (up 2.35%) no longer stands	`results/model_gate/V25_VS_V24.md`, `cluster_blink`
The verdict's false acceptance	at 20 pieces of work a decision a give-back step that truly costs 3% is kept 28% of the time and one costing 5% 14%, a free step 60%; at 200 pieces 26%, 7% and 66%	`results/model_gate/V25_VS_V24.md`, the verdict model; the strict form refused on 19 October (`v12-verdict-study`)
The trade between muscles judged on the organism	the founder's order of 19 October (`DISCLOSURES.md`, section 3): no code, model or row yet	`omnicompass/verdict.py` (each muscle judged on itself)
The immune system on every knob	the founder's order of 24 October: it stands on two knobs, the Kubernetes autoscaler's target and the Kafka wire	`omni_controller/controller.py` (`_immune_native`), `tools/run_kafka.py`
`--give-back-only` leaves the engine	the order of 31 October struck the cloud's rule and said the flag leaves with the next version; it is still in the governor	`omni_controller/controller.py` (`apply_give_back_only`)
The cloud's beat and the work per dollar in the cloud model	through a cloud no beat was admissible on the corrected ladder (every beat raised the machine-hours, every beat but 90 s	`results/model_gate/V23_LADDER_CORRECTED.md`, `docs/PACE_PREREGISTRATION.md` amendments 4 to 6,

Change	Why	Evidence so far
	the pods waiting); the cloud model sends a fixed load and reads no bill, so it cannot read the work per dollar a cloud tune is judged by	`docs/THE_TUNE.md`
Kafka's 20 s notch	the burst's peak queue up 30.6% at run C's setting, inside the seeds' spread	`docs/OMNI_V22.md`

CHAPTER 29

How Much of the Engine the Tests Run

Line coverage of every Python file in the engine that stands (omni-v26), under the whole test suite: the unittest suite and every file `tools/function_tests.py` runs. Measured with coverage.py by `python3 tools/engine_coverage.py --measure` on commit `e45ac4a0ccc2`; `tools/engine_coverage.py --check`, run by `verify.py`, fails a push where this page is not what `results/ENGINE_COVERAGE.json` records.

71% of the engine's 11,501 statements run under the tests (8,205 run, 3,296 not). Coverage counts lines a test executes, not what it asserts: the properties the tests check are in `tests/test_engine_properties.py`, and the proofs of the core in `docs/ENGINE_PROOFS.md`.

The 8 runners omni-v15 took into the fingerprint (the data stores', the swarm's, MuJoCo's and the CPU power runner, `tools/run_*.py`) hold 3,631 of these statements, 51% of them run under the tests: each is run whole by its own benchmark on GitHub, A, B and C, rather than by a unit test. The other 45 Python files, the engine as it stood before them, hold 7,870, 81% run. The whole figure fell when those runners came in; no test was lost.

29.1 Where the tests reach least

Files under 60%: `tools/run_pgbench.py`, `tools/run_citylearn.py`, `omnicompass/stack_sim.py`, `omni_orchestrator/control.py`, `omnicompass/closure.py`, `omnicompass/speed.py`, `omnicompass/mathdrive.py`, `tools/run_kafka.py`, `tools/run_redis.py`, `omnicompass/shield.py`, `tools/run_swarm.py`, `tools/run_sysbench.py`, `tools/run_ycsb.py`. The CityLearn runner and the runners of the data stores and the swarm are exercised by their own benchmarks on GitHub (`citylearn.yml`, `redis.yml` and the rest, three runs on every engine) rather than by a unit test; the stack simulator, the shield and the speed and mathdrive modules hold paths the live governors do not call. Raising each to the level of the rest is the next tests' work: no engine file changes for a test.

PART THREE

The Physics: the Compass and the Nervous System

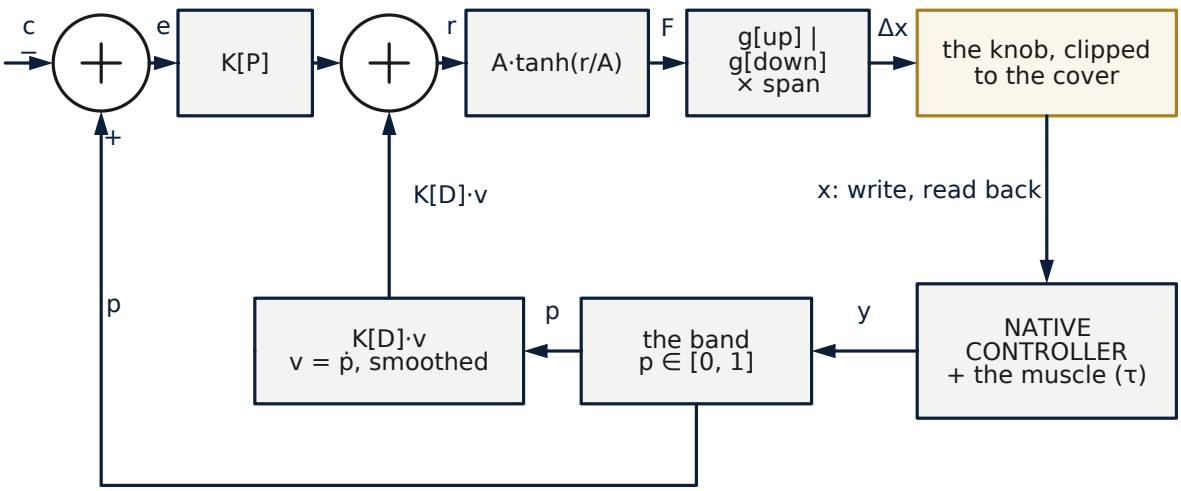
Push and pull, the band and its cushions, the physics of a processor, and the two-way wires that carry the force from the brain to every muscle and back.

CHAPTER 30

The Compass: Push, Pull and the Two Forces

The compass (`omnicompass/compass_law.py`) is the law that carries the engine's push and pull to every muscle.

Two bands.



- **The cover**, a knob's hard range (the device's or the operator's lowest and highest setting). Every write is clipped to it. Nothing Omni-Compass computes can set a knob outside it.
- **The compass**, the service reading as a position from 0 (calm) to 1 (the service line). Omni-Compass pulls that position to the bottom of the compass, the middle (0.5 by default; an operator may set it lower for extra margin). The walls run from 0.05 to 0.95; the last 5% on each side, 10% in all, is cushion.

The force. F = A tanh((K[P] (p - center) + K[D] v) / A), where p is the position, v its rate of change, A the authority.

- **Pull:** K[P] (p - center), gentle near the bottom, stronger up the walls.
- **Push:** K[D] v, the force that meets whatever is shoving the position, and the friction that stops it sloshing. With K[D] at or above critical damping the position glides to the middle and stops, with no overshoot and no ringing. Overshoot is wasted energy: force spent going the wrong way and spent again coming back.
- **Smooth, never a hammer:** tanh bends the force over into its maximum instead of slamming into a wall.
- **Fail up:** past the 0.95 wall the up side goes to its full force at once and the down side may not act until the position is back inside the compass.

Two forces: antagonist pairs. Like the muscles of an arm, every plug has an up side (adds capacity, power, cooling, speed) and a down side (takes it back), each with its own gain, because adding and taking back do not

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

c the centre of the band; y the reading; p the reading's position in the band; e = p − c; v = ṗ smoothed; r the raw force; F the force after the saturation; Δx the step; x the knob. Fail up: p ≥ 0.95 → F = A at once; the down side held until p is back inside the band. No take-back while the reading climbs above the centre (F < 0 with v > 0 and p > c → F = 0). K[D] is set from the muscle's own response time τ (critical damping), never tuned by hand.

Figure 10. Block diagram: the compass law as a closed loop on one muscle. The reading y of the native controller and its muscle (response time τ) is placed in the band as the position p; the error e = p − c against the centre c, through K[P], is summed with the damping term K[D]·v (v the smoothed rate of change of p) into the raw force r, saturated to F = A·tanh(r/A), scaled by the gain of its direction (g[up] or g[down]) and the knob's span into the step Δx, and clipped to the cover before it is written and read back. The loop closes through the plant: one write a decision, one reading back.

cost the same: a new machine takes minutes to boot; giving one back is instant. Where a machine has two wires, each side gets its own lever:

Muscle	Up force	Down force
GPU card	clock ceiling raised	power limit lowered (the lid)
Kubernetes	scale out	scale in
Cooling	chiller on, colder setpoint	warmer setpoint, unit released
Battery	discharge	charge, reserve held
Vehicle, joint	motor effort	braking, regeneration

Why the GPU needs both wires. A card's firmware boosts its clock as high as it may while there is work, and its power limiter knocks the clock back each time the draw crosses the limit; on a busy card this happens many times a second, at the top of the clock range where each extra step of speed costs the most watts. With one wire (the power limit) a governor can only move the wall the boost pushes against. With two wires, the clock ceiling sets how high the boost may climb and the power limit becomes a lid that rarely needs to act: the card runs at the bottom of its compass instead of fighting itself at the top.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

What the card taught us. Two rules make the difference between saving energy and spending the customer's time. First, *race while work waits*: when the card is saturated, both wires go to full at once, so a burst is always served at full speed; the compass paces only the slack between bursts. Second, *never slower than the card on its own*: the governor learns, from the card's own meter, the clock and the draw the card reaches by itself while busy, and never sets the clock ceiling or the lid under them. Without these rules the first real card saved 3.5% of its energy and made the slowest answers 58.5% slower (2 October, on a controller since replaced: `results/gpu/run-20261002T082232Z/GPU_REPS.md`); with them, the modelled card saves energy with the slowest answers at native speed or faster (Chapter 60, and `docs/GPU_PREREGISTRATION.md`, amendments 6 and 7).

30.1 The same law on every stack, and what differs

The law is written once (`CompassLaw`), and three declared numbers fit it to a muscle: the **decision period** *dt* (how often the governor decides), the muscle's **response time** tau (how long the service reading takes to follow the lever), and the **cover**. From tau and *dt* the law derives its own damping gain, K[D] = (2 sqrt(K[P] tau / dt) − 1) dt, which is critical damping for a first-order muscle under a proportional-derivative pull: the position glides to the center and stops. Nothing else is tuned per stack. The table below is the complete list of the compass's settings on every stack in this manual, so a referee can see that the "gains" differ only through the declared physics:

Stack	Reading (the wire in)	Line	Center	Decision period	Response time	Cover of the knob
Kubernetes, the HPA target	the mean response time of the latency window	the operator's SLO (500 ms)	0.4	15 s	the pods' start time	[0.6 × the operator's target, the operator's target]
Kubernetes, the machines	the same, through the release gate and the verdict	the same	0.4	15 s	a machine's wake	[the floor of 2, every machine]
PgBouncer, the pool size	time in the server plus time waiting for one, per transaction	50 ms	0.4	1 s	2 s	[2, PostgreSQL's limit minus 10]
Kafka, the consumer count	the group's own end-to-end latency, mean of the last second	500 ms	0.4	1 s	3 s (a rebalance)	[1, the topic's partitions]

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Stack	Reading (the wire in)	Line	Center	Decision period	Response time	Cover of the knob
Redis, the memory ceiling	the application's request latency, mean of the last second	2 ms	0.4	1 s	2 s	[16 MB, 512 MB]
MongoDB, the storage-engine cache	the server's own mean read latency, last second	1 ms (set on the tuning workload's smoke run, from 2 ms)	0.4	1 s	2 s	[256 MB, 2,048 MB]
MySQL, the InnoDB buffer pool	the server's own mean statement latency, last second	0.6 ms a statement (set on the tuning workload's smoke runs, from 1 ms)	0.4	1 s	2 s	[128 MB, 2,048 MB], in 128 MB chunks
A drone's cruise override	the drone's tracking error	0.25 m, the declared safe error	0.5	one control tick (48 Hz)	1 s	[1.0, 2.0] × the planner's cruise
A substation's tap	the bus voltage in its band	the band's edge	0.5	one solve	a week of evidence before a step down	the tap's own range, one tap per move
A robot axis's speed	the axis's tracking error against its takt	the declared error	0.5	one control step	the axis's response	the axis's own limits
A GPU's clock ceiling and lid	the mean response time of the last 5 s	the SLO	0.4	2 s	the card's response	[the card's own busy clock, its top clock]; [the busy draw + 10%, the start limit]

The center is 0.4 wherever the reading is a service time (the "service profile" of the Kubernetes adapter, so that the service sits a little below the middle of its band with margin for a burst) and 0.5 where the reading is a physical error. A **cushion** of ±0.05 in force moves nothing, so a reading that sits at the center with the usual jitter does not make the knob chatter. These are the same numbers in every preregistration and every table; none was changed after a result was seen.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

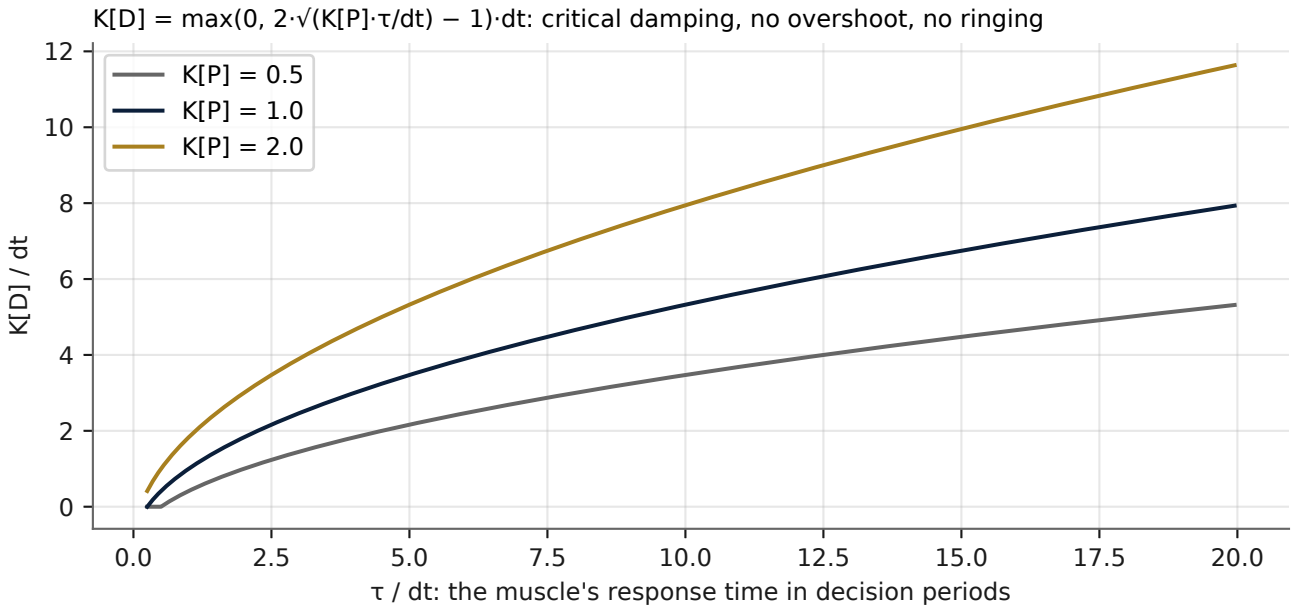


Figure 11. Curve: the damping gain the law sets from a muscle's response time, K[D] = max(0, 2·√(K[P]·τ/dt) − 1)·dt, for three values of K[P]. A slow muscle (large τ in decision periods) gets more damping, so the loop is critically damped: no overshoot and no ringing, whatever the stack.

30.2 Direction rules: how a force becomes a move

The force is a number between −1 and +1. Each stack turns it into a move on its knob by a direction rule declared in its preregistration, always of the same shape: a positive force adds capacity in proportion to the force (ceil(force / 0.10) notches, so full force adds ten notches at once, capped by the cover), a negative force takes one notch back per decision, and only when the resource it would take is demonstrably idle (an idle consumer that read nothing in the last second, an idle server the pooler itself shows idle, a cache with nothing evicted in the last second) and only after a **dwell** of a few seconds since the last change, so a knob that was just moved is not moved back by its own transient. At 95% of the line the knob **fails up**: every consumer the topic can use, the pooler's own setting handed back, a quarter of the cache's cover added at once, the planner's own cruise, the card's own clocks. The up side is fast and the down side is slow and gated because adding and taking back do not cost the same, and because a gain bought by taking something back must be able to prove itself before it is kept.

Written out stack by stack, from the preregistrations, the rule reads as follows; the unit, the cover and the fail-up move are each the stack's own, and the shape is the same in every row.

Stack	The knob and its unit	The cover	One notch back, when idle	Fail up at 95% of the line
Kubernetes (the cluster)	worker machines in service	the floor of two to every machine the operator has	one machine a decision, when the remaining machines would carry	one machine up at once

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

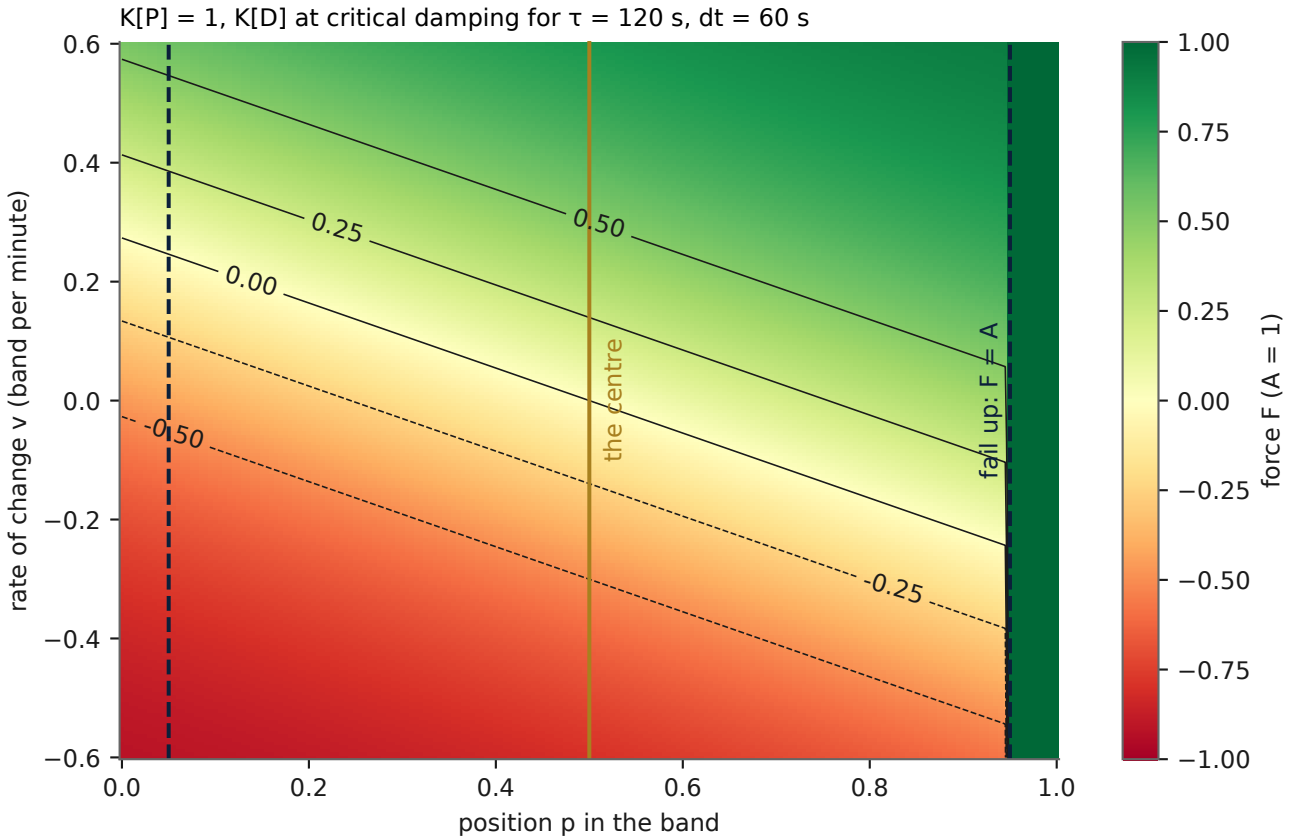

Figure 12. Grid: the force F over the band position p and its rate of change v, for K[P] = 1 and K[D] at critical damping with τ = 120 s and dt = 60 s. Green pushes capacity up, red gives it back; the no-take-back rule zeroes the force where the reading climbs above the centre, and past the upper wall (p ≥ 0.95) the force is the full authority A whatever v reads.

Stack	The knob and its unit	The cover	One notch back, when idle	Fail up at 95% of the line
			the load far under the wall	
PostgreSQL behind PgBouncer	the pooler's pool size, server connections	[2, 90]: the floor of two, never within ten of PostgreSQL's 100	one connection a decision, when the pooler itself shows a server idle	the pooler's own setting (20) handed back at once
Apache Kafka	consumers in the group	one to the topic's partitions (8)	one consumer a decision, when a consumer read nothing in the last second	every consumer the topic can use

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Stack	The knob and its unit	The cover	One notch back, when idle	Fail up at 95% of the line
Redis	the memory ceiling, MB	[16, 512] MB	one notch a decision, when calm and nothing was evicted in the last second	a quarter of the cover added at once
MongoDB (WiredTiger)	the cache size, 64 MB notches	[256, 2,048] MB	one notch a decision, when calm and nothing was evicted in the last second	a quarter of the cover (448 MB) added at once while full
MySQL (InnoDB)	the buffer pool, 128 MB chunks	[128, 2,048] MB	one chunk a decision, when the miss share is under 1%	four chunks at once while the pool is full

Two things in the table deserve a reader's attention. The "when idle" column is never a guess from the knob's own value: it is a reading from the stack's own counters (the pooler's idle servers, the consumer's last fetch, the cache's eviction count, the pool's disk reads against its requests), so the law gives back only what the stack itself reports it is not using. And the fail-up column is the stack's own fastest safe move, not a multiple of the notch; where the stack has a controller of its own (the pooler, the planner, the card's firmware), fail up means handing the knob back to it, which is the one move that can never be behind native by construction.

30.3 The do-no-harm gates inside the law

Three gates sit inside the law itself, each a consequence of a loss seen on a tuning case and each disclosed in the preregistration that carries it:

- **The verdict** (section 1.2): a slow knob moves only where a paired trial on the muscle shows no more than 2% cost.
- **The slack gate on speed knobs** (Omni v3): a motion axis that is busy more than half the time at full speed keeps its speed native, because spending its slack as speed when it has none would only cost energy. This gate is what turned the v2 "service tradeoff" on the Physics realm and the tower into "superior within guardrails" on v3, and it is the one rule that distinguishes v3 from v2.
- **The full-cache gate** (Redis): a miss in a cache with room to spare is a cold miss that no ceiling can mend, so the ceiling grows only while the cache is at 90% of it or more. On the tuning workload without that gate the law raised the ceiling to 500 MB while 21 MB were in use; with it, the ceiling follows the working set.

The same gate recurs, in the form each store's own gauges allow, on every memory knob that followed, and each form was fixed on the tuning workload and disclosed before the counted runs:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **MongoDB's storage-engine cache** grows by a notch only while the cache is full and the server's own read latency is above the centre of its band, and gives a notch back only while calm and nothing has been evicted in the last second (`docs/YCSB_PREREGISTRATION.md`). The smoke runs showed the line itself had to be set from the server's own readings (0.15 to 0.46 ms under a 2 ms line left the law nothing to do), and it was set to 1 ms before the counted runs.
- **MySQL's buffer pool** grows by a chunk only while the pool is at least 90% full of data pages and the server's own statement latency is above the centre, and gives a chunk back only while the **miss share**, pages read from disk as a share of the pool's requests in the last second, is under 1% (`docs/MYSQL_PREREGISTRATION.md`). The earlier rule, "no disk reads in the last second", was never satisfied on the tuning workload: InnoDB keeps stale pages resident, so a pool once filled reads full for ever, and a few new-page reads a second never stop even when the working set fits, so the pool the law had grown was never given back (877 MB held on average against native's 512 on that smoke run); the smoke record says so, and the miss-share rule replaced it before run A.

What the three forms share is the reason: a memory knob has no slack to spend unless the memory is both full and being missed, and memory given back while it is being missed is not a saving but a cost moved to the disk. The gate is written in each harness in the store's own units and checked by that harness's own tests against a stand-in server, so that a reader can see in the preregistration exactly which reading opens the gate and which closes it.

30.4 The profiles and the pedals

The compass has two **profiles**, service (the default) and batch, which differ only in what the pedals do with a pile of work: in the service profile the law paces the slack; in the batch profile cruise puts every machine in service while work waits for a place and idle takes them straight to the floor when the queue is done (section 1.3). Both are written out in the Kubernetes preregistration (`docs/K8S_COMPASS_PREREGISTRATION.md`, rules 7 and 8, amendment 9), both ran in the batch test, and the result (Chapter 60) is machines 19% to 23% fewer over the whole window and 29% to 35% fewer after the queue finished, with the queue itself finishing no later beyond the noise.

30.5 The reflex rule: one body, one brain

Everything in this chapter so far is the force: where a reading sits in its band, how hard the compass pushes, in which direction, and which gates stand in the way. This section is the rule that decides when the force may become a new setting. The founder's order of 10 October 2026 states it in one line: what the brain sends to a muscle has to coincide with what the muscle sends to itself and where it is at. Made into rules, it reads:

1. **Signal out, the muscle moves, the brain feels the full reaction, then it decides.** A trial runs to its full measurement and is never ended by the calm it causes. Only the wall (a fail-up) or the engine's own time limit ends a trial early.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

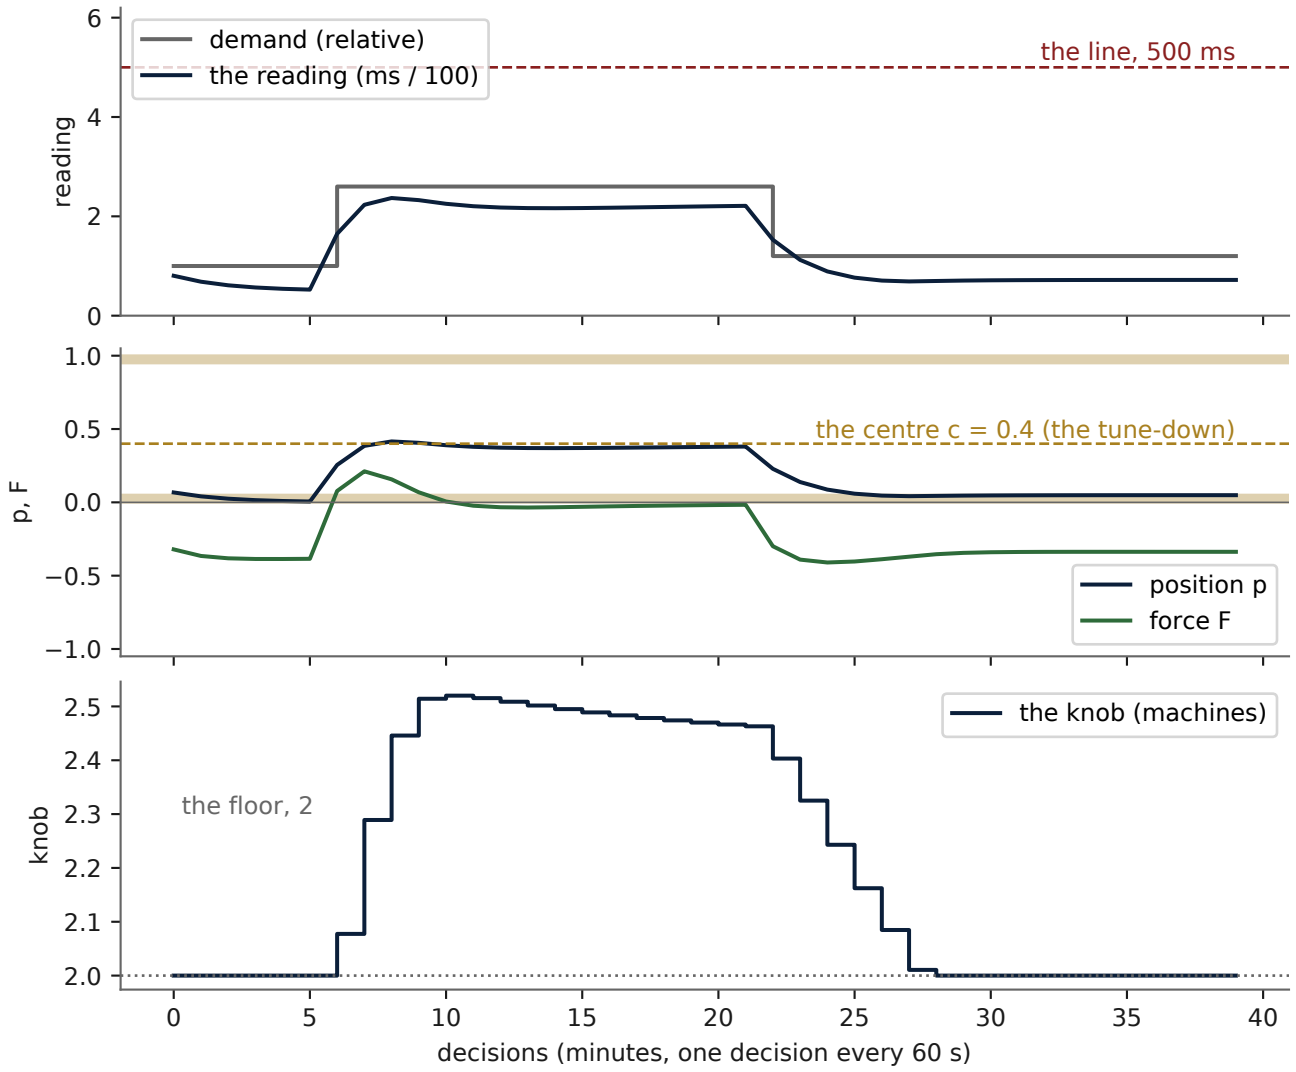

Figure 13. Modelled trace: the compass law answering a load step on one muscle (class S: the law's own code, omnicompass/compass_law.py, on a first-order muscle with τ = 120 s and a decision every 60 s). Demand rises 2.6-fold at minute 6 and falls at minute 22; the reading climbs toward the line, the position p leaves the centre c = 0.4 (the tune-down), the force F rises and the knob adds machines at once; as the reading settles the force crosses zero and the knob is given back one step at a time toward the floor of 2.

2. **No forcing.** A spend is tried only when the muscle's own reading says there is something to buy (messages waiting, a cache missing, clients queued); a give-back only when the whole body is calm. The force is an urge, smooth, never a hammer.
3. **One body, one brain, one tick a second.** Everything is read first: every muscle's state, every service's speed and work, the host's processor, memory and energy where a meter exists. Then the brain decides. The cost it judges is the body's cost, the Omni index's own arithmetic over all the work, all the speed, all the machines and all the resources, never one muscle's.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

4. **Hurt nothing anywhere.** On top of the body's cost, a guard for every part: a step is refused if any one service read LOSS beyond its cushion, even when the body's total improved.
5. **One trial at a time inside a body.** Two muscles moved together cannot be told apart, so the body grants one new trial at a time, to the muscle asking loudest whose own condition holds. Every other muscle keeps acting inside what it has already proven.
6. **Nothing is permanent.** Every allowed step is tried again on the recheck and pulled back when it stops paying; a muscle at native is asked again whenever its signal returns. Native is where the brain stands when it has not yet been shown a reason, never a verdict.
7. **The wall belongs to the body.** If any service reaches its line, the trial stops, that step is undone, and every force in the body lifts off: the law's own lift, not a reset.

The trial itself keeps four rules, each learned from a measured run (`docs/OMNI_V4_PLAN.md`, section 4): samples count only once the muscle reports itself settled; a spend on a queue or a cache is judged by the muscle's own reading, with the body's cost taken at the settled state; the reference and the trial are compared at the same load; and where single notches read flat, one scout step to the far side of the cover decides whether there is a hill to climb at all.

Which engine enforces what. In Omni v3, and in the v5 and v6 engines that carry its verdict, the verdict tries a slow knob on the muscle itself before it moves it (section 1.2), and the live harnesses carry the same verdict around every live knob (section 45.4). Omni v4 is the engine written to enforce all seven rules on every wire by construction: one body file that every muscle's wire passes through, the trial rules inside the verdict, and no wire that can write around them. It is designed (`docs/OMNI_V4_PLAN.md`) and not yet built; when it is, it carries its own fingerprint, the package version follows it, and every result in this book is run again on it. The theory of the rule is the chapter "The Reflex Rule" in Part One of the book.

CHAPTER 31

The Physics of a Processor

A GPU's firmware raises its clock one step at a time whenever there is work and room; each higher clock needs a higher voltage, and dynamic power rises with the clock times the square of the voltage, so the top of the clock range is where each extra step of speed costs the most watts. When the draw crosses the power limit, the firmware knocks the clock down several steps; with room again, it climbs again. On a busy card this repeats many times a second. The clock saws against the limit, the overshoots burn watts before the limiter catches them, and the card spends its time at the steepest part of its power curve. The power is the burner; the cooling removes the heat at its own pace; the limiter turns the burner down so the cooling can catch up, and the boost turns it back up.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The firmware does not aim at a balance point because it cannot see the job: it does not know whether the work is a response due in milliseconds or a batch due overnight, the right point moves with the workload, the room and the chip, and a limiter is simple to prove safe. The vendor default is set for maximum performance, and the electricity bill is the customer's.

Omni-Compass sits on the customer's side, where the job's service line is known. It holds two wires: the clock ceiling sets how high the boost may climb, and the power limit becomes a lid set just above what that ceiling draws. The boost stops at the bottom of the compass instead of slamming into the wall; the limiter rarely needs to act. Every watt kept off the chip is saved twice in a data center: once at the chip and again at the chillers that would have carried its heat.

CHAPTER 32

The Two-Way Nervous System

Every muscle is wired both ways: a sensory wire in (its meters) and a motor wire out (its knob), with the read-back closing the loop. Between them sits the nervous system (`omnicompass/nervous_system.py`), which decides how much authority each organ has at each moment:

- **Expand is always allowed** (except under a security hold): adding capacity, power, cooling or protection never waits.
- **Contract needs calm and a clean service record:** giving anything back is allowed only while the organ is calm enough and service has been inside its line for the clear time, 180 s; continuous organs give back at most the calm share of their surplus per decision; discrete organs one unit at a time, through a release gate.
- **Fail up:** while service is breached, the knob returns to native at once.
- **Blind means hold:** if a sense goes stale or unreadable, nothing is given back until it returns.

One brain reads every organ at once. Because one law sets every knob, no two muscles fight: when the GPU's watts turn to heat, the cooling knob already knows it is coming; when pods scale up, the power envelope is ready.

"Two-way" is a statement about wiring, and it is checked, not assumed. Each muscle's plug (Chapter 42) carries exactly one sensory wire and one motor wire, and the wire check that must pass before any write (section 42.4) proves that the wires move: a value written through the motor wire is taken by the device and read back as the value sent, and the snapshot is restored and read back at the end. No governor writes a knob whose wire check has not passed, because a knob that can be written but not read back cannot be handed back with proof. What the wire check does not prove, section 42.5 says plainly: that the governor is reading the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

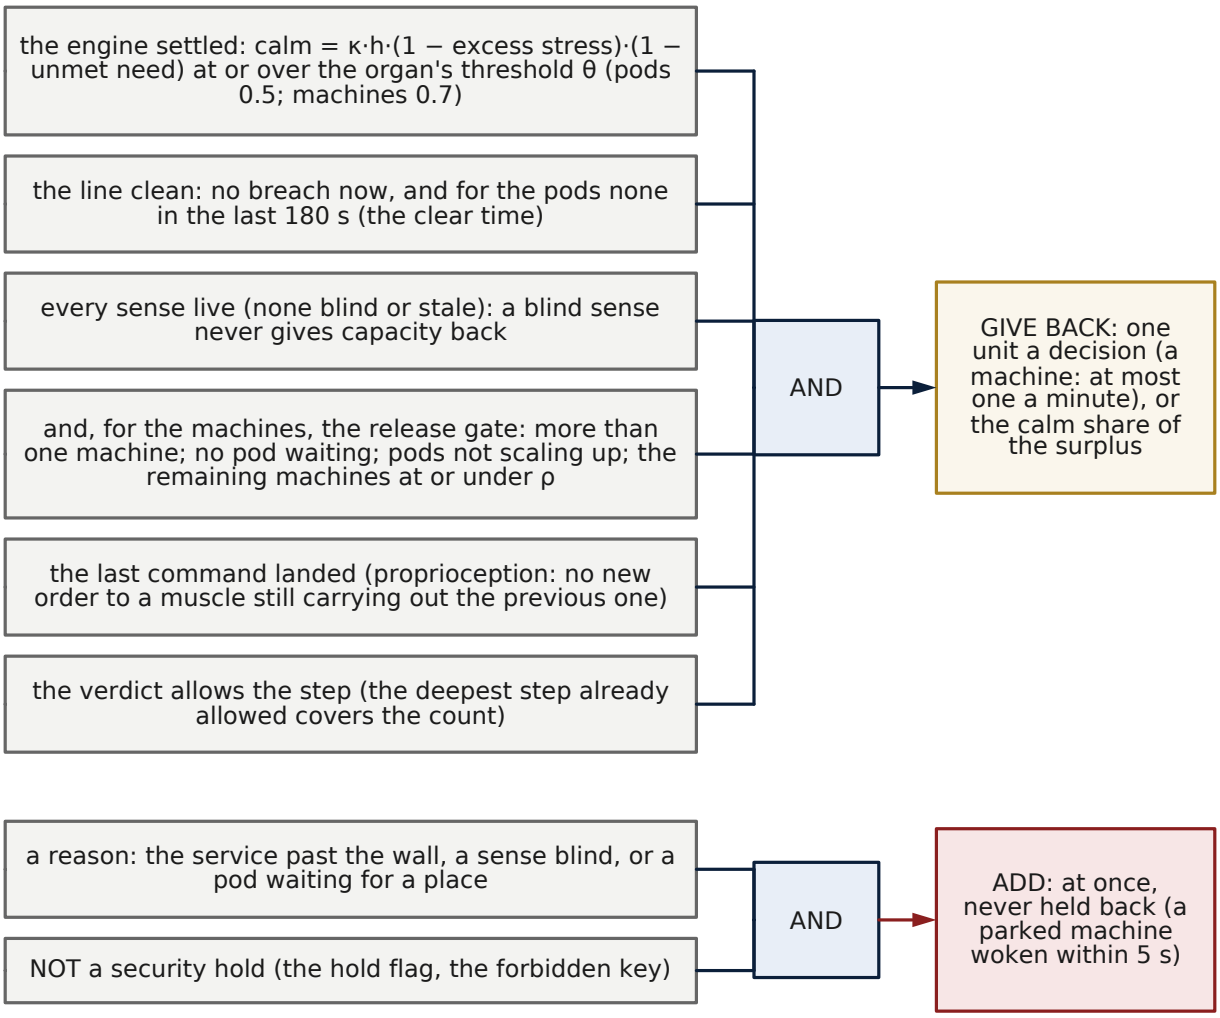

Figure 14. Logic diagram: the nervous system's authority to add and to give back. Giving back needs every condition at once: the engine settled (calm = κ·h·(1 − excess stress)·(1 − unmet need) at or over the organ's threshold θ, 0.5 for the pods and 0.7 for the machines), the line clean (no breach now; for the pods none in the last three decisions), every sense live, for the machines the release gate's own reasons, the last command landed, and the verdict's step allowed; adding needs only a reason (the service past the wall, a sense blind or a pod waiting) and the absence of a security hold.

The asymmetry is deliberate: adding is cheap to undo and expensive to delay; taking back is cheap to delay and expensive to get wrong.

right gauge for the knob; that is what the watching arm is for. The receipts of every run therefore carry, for every write, the value sent and the value the device reported, side by side, and a reader who wants to know

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

whether the governor's hand was really on the stack can check the two columns rather than take the summary's word.

The four rules above are the whole of the nervous system's authority model, and they are asymmetric on purpose. Adding is cheap to undo and expensive to delay, so it is never gated beyond the security hold. Taking back is cheap to delay and expensive to get wrong, so it is gated three ways: by calm (the engine's own state must report that the body is settling), by the service record (the gauge must have been inside its line for the last 180 s, not merely at this decision), and by the release gate's reasons, which are written into the audit every time the gate holds (section 32.1). Sections 32.2 to 32.4 take the three ideas that make this safe at scale, the governor's sense of its own hand, the rule that a missing reading is a hold and not a guess, and the case for one brain over many, and give the evidence for each from the live runs.

32.1 Authority, and the release gate

Authority is how far the nervous system lets an organ move in one decision. It is granted from the engine's state (section 12.3): an organ in a calm body with a clean service record may give back; an organ in a stressed body may only add. On Kubernetes the **release gate** (`omnicompass/nervous_system.py`, `node_release_gate`) lets one machine be given back only when every one of the following holds, and writes the first reason that fails into the audit so a reader can see why a machine was kept, in the order the code tests them: more than one machine is in service; no pod is waiting for a place; the pods are not scaling up; the line is not breached now and its feed is live; the remaining machines would run at or under the utilisation target ρ (used ÷ ((n − 1) × one machine's capacity) ≤ ρ, ρ the engine's own demand clipped to [0.5, 0.95]); the machine organ's own engine state grants contraction (`authority()`: its calm at or over θ[machines] = 0.7, its line clean, no security hold); every sense is live; and the last machine command has landed (no new order goes on top of one the cluster has not yet carried out). The controller adds one rule of its own: at most one machine a minute, however often it decides (v7). The gate is asked only when the compass law itself asks for a machine back ($F < -0.2$, the reading under the centre, the verdict's deepest allowed step covering the count), never on the max and never during a trial, and cruise overrides it: while work waits for a place, every machine stays in service. One machine per decision is the rule in the slow, reversible direction; past the wall, one machine up at once.

What the gate writes, in a real run. The first repetition of the first kill-scenario run (`results/live/raw/run-37716845219/paired-1/`, the omni arm's `audit.jsonl`) holds 114 decisions and 42 writes. Its gate records read, in the governor's own words, "release permitted" eleven times, each with the utilisation the remaining machines would carry after the release (0.034 to 0.153, all far under the utilisation target ρ); "node organ has no contraction authority" once, a calm cluster whose engine state had not yet earned the right to give back; and "latency breached now; node organ has no contraction authority; a sense is blind" once, three reasons at once in a decision whose latency sense read stale, every one of them a reason to hold. A reader can therefore see, decision by decision, not only what the governor did but why it declined to do the rest, and the first reason that failed is the one written, so that a machine kept in service always has a stated cause.

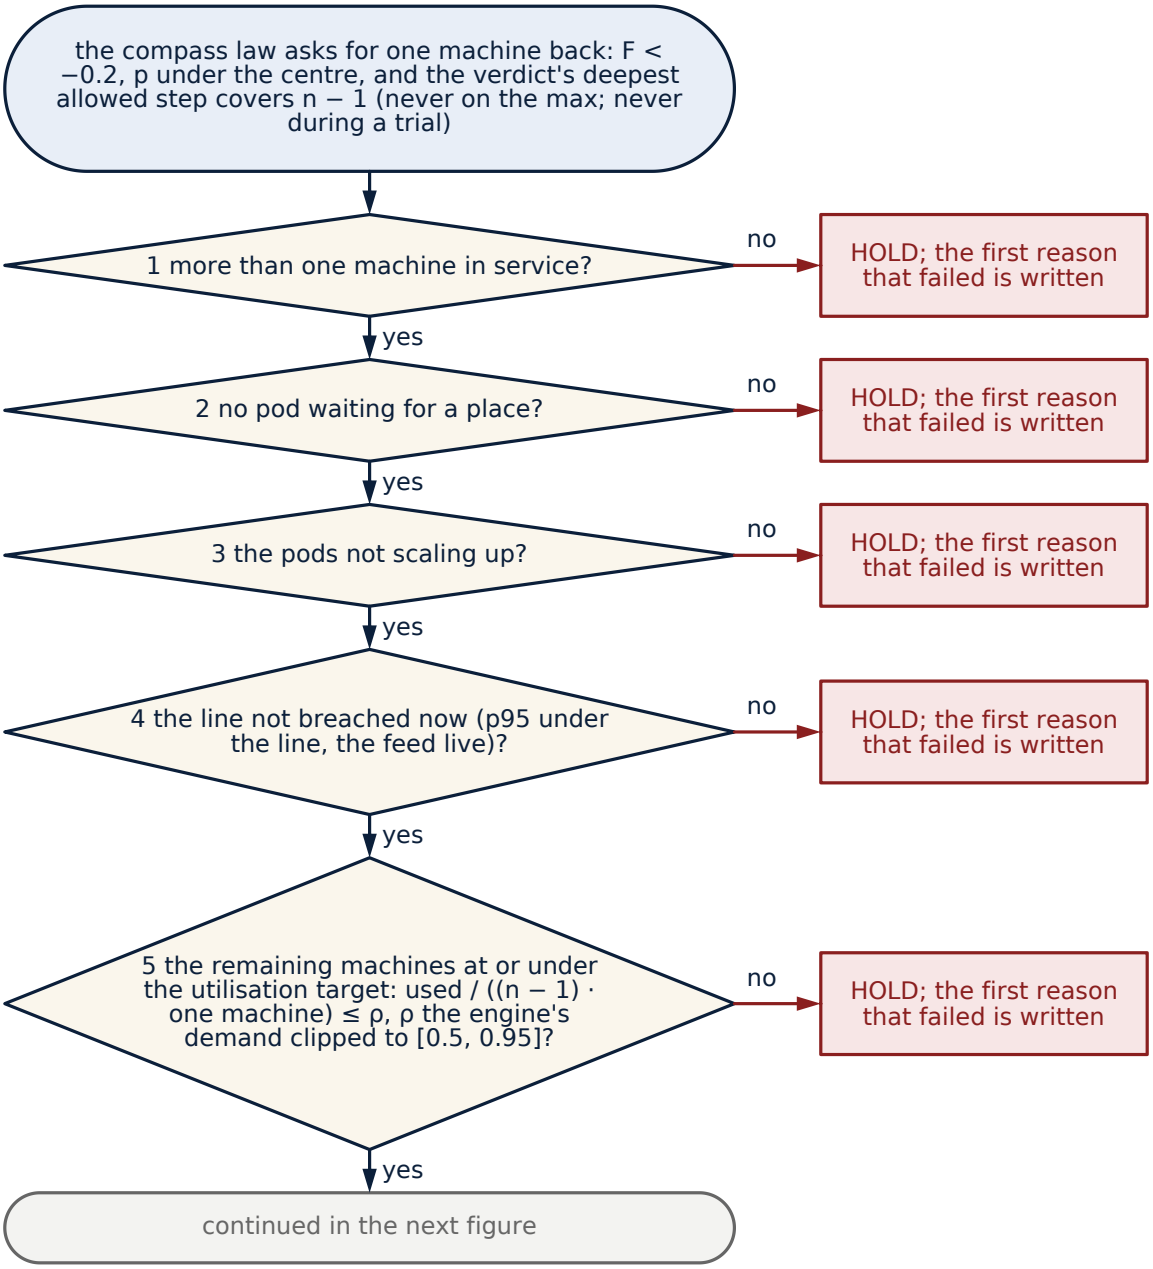

Figure 15. Flowchart: the release gate, reasons 1 to 5. The compass law asks for one machine back (F < −0.2, the reading under the centre, the verdict's deepest allowed step covering n − 1; never on the max, never during a trial). The gate then tests, in the code's own order: more than one machine in service; no pod waiting for a place; the pods not scaling up; the line not breached now, the feed live; the remaining machines at or under the utilisation target ρ (used ÷ ((n − 1) × one machine) ≤ ρ, ρ the engine's demand clipped to [0.5, 0.95]).

The first reason that fails holds the machine and is written in the audit. Continued in the next figure.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

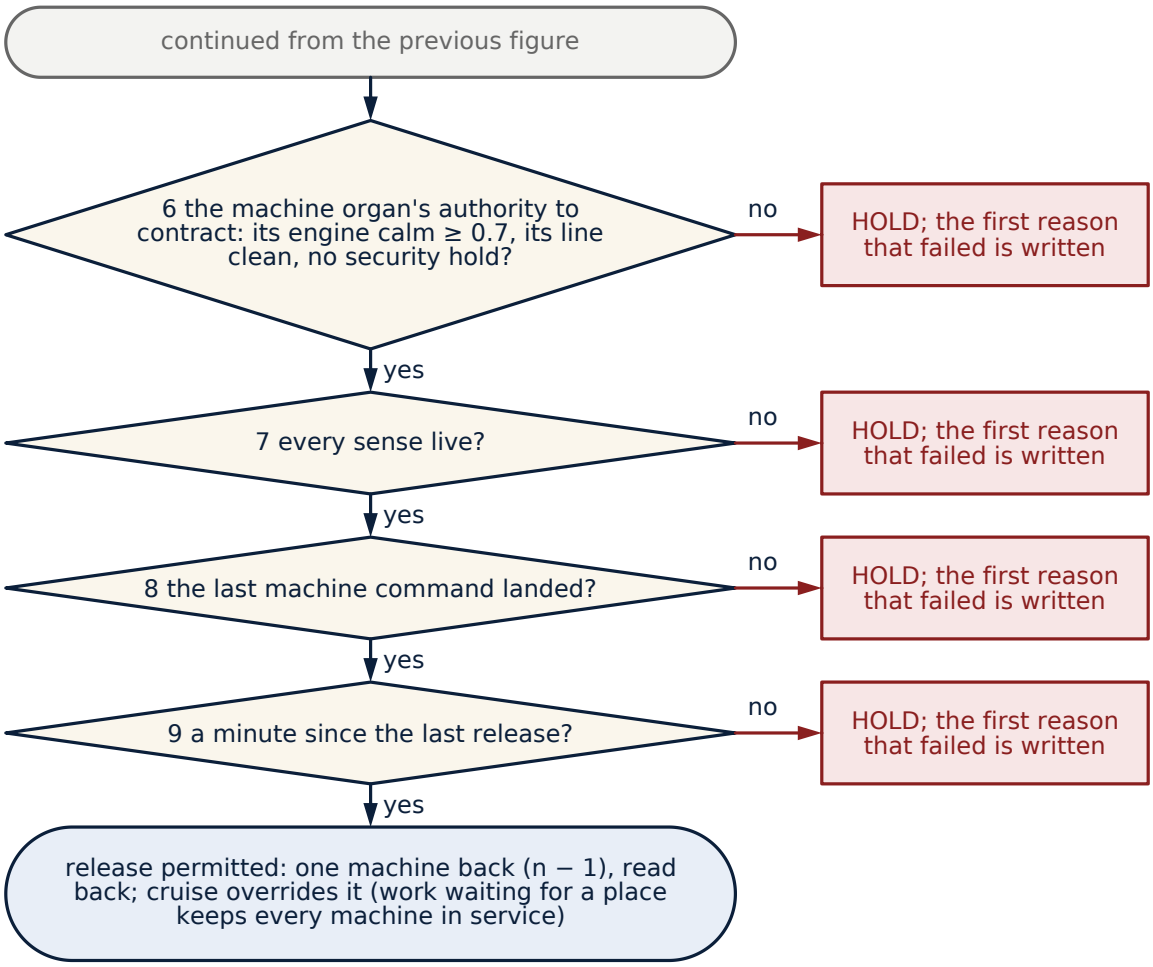

Figure 16. Flowchart: the release gate, reasons 6 to 9 and the release. The machine organ's own authority to contract (its engine calm at or over θ = 0.7, its line clean, no security hold), every sense live, the last machine command landed, and a minute since the last release; only then is one machine given back and read back. Cruise overrides the release: while work waits for a place, every machine stays in service.

32.2 Proprioception and the one-writer rule

The nervous system knows where its own levers are. Every write is read back from the device (the plug contract, section 8), and the audit records both the value sent and the value the device took. If a lever is found at a value Omni-Compass did not write, someone else owns it: the governor stops writing that lever and leaves it alone, because restoring over it would fight the new owner. This is **proprioception**: the governor's sense of its own hand. It is the reason a wrong installation leaves a signature in the receipts (section 42.5) rather than a silent error, and it is what the wire check proves before anything runs.

The rule begins with the **snapshot**. The governor reads every knob it may move once, at the start, before its first decision, and that reading is the operator's setting for the whole run: every reset, every hand-back and every kill returns the knob to the snapshot, never to a value computed later, and the receipts record the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

snapshot beside the final read-back so that a reader can check the two are equal. The rule continues with the **read-back** after every write: the plug sends a value, waits for the device to take it, and reads the device's own report of what it holds. Where the device takes time to apply a setting, the plug knows that and does not mistake the transition for a foreign hand. The clearest case is MySQL's buffer pool, which the server resizes in chunks over several seconds and reports as it goes: the plug reads the server's own resize status and treats a pool caught mid-resize as its own write in progress, not as another owner's value, and waits for the server to report completion before it judges the write (`tools/run_sysbench.py`, `BufferPool`). The same shape holds on the Kubernetes autoscaler's bounds, Redis's memory ceiling and MongoDB's cache size: the value is read from the device's own console, and only a value that the governor neither wrote nor is waiting on is read as someone else's.

What follows from a foreign value is deliberately conservative. The governor does not restore over it, because an operator who changed a knob by hand meant to, and a second controller that changed it is a conflict to be reported, not won. The lever is left where it was found, the audit records the value and the time, and Omni-Compass goes on supervising the other levers. A reader of the receipts who finds such a record knows at once that two hands were on the stack, and the paired run that contains it is read with that in mind.

32.3 Blind means hold, and fail up

A sense that goes stale or unreadable is not read as calm. It is read as **blind**, and while any sense is blind nothing is given back; the knob holds, or, if the service was breached when the sense went blind, returns to native at once. In the fault test on real Kubernetes the response-time probe is deliberately paused for a minute in every arm; the audit shows the governor holding through the blind minute and resuming when the sense returns, and the table shows no row behind for it. The rule is simple to state and strict in effect: Omni-Compass never acts on a reading it does not have.

The rule was also tested without being arranged. In the two-hour robustness run on real Kubernetes (`results/live/V3_ROBUST_LONG.md`), the cluster's own API answered a handful of the governor's reads of the autoscaler with a server error, two or three times a run out of the 120 decisions a two-hour window expected at the 60 s period of that engine. Each of those decisions is in the controller's log with the reason the API gave, each was held (no write, no hand-back, no guess), and the governor took its next decision on schedule when the API answered again. The preregistration had said in advance that such decisions would be shown with their reason and not judged, and that is how they appear in the table: 97.5% of the expected decisions valid, the failed ones counted and named, the knob handed back at the end of every run. A referee who wants to see the rule in the same rule written by the gate itself can find it in the kill test's receipts (section 32.1), where a decision whose latency sense read stale is held with "a sense is blind" among its reasons, and in the fault test's blind-probe window, where it was arranged on purpose. The point in every case is the same: a stale or missing reading produces a hold, never a move, and the hold is in the record.

32.4 Why one brain

The alternative to one brain is a controller per layer, each tuned alone: an autoscaler that adds pods while a power cap is trying to hold the machines down, a cooling loop that chases heat the clock governor is about to remove. These controllers fight because none of them knows the others' intent. One law that sets every knob from one state cannot fight itself: the force on each lever is computed from the same reading of the same body at the same moment. This is also why the modelled organisms are run whole, at up to 1.7 million muscles on one clock (section 34.4): the question they answer is whether one brain stays coherent at that size, and the reading at every size is the same to the digit.

One brain also has to stay the same brain over time, and that is a measurable claim. The two-hour robustness run (section 60.15) measures the governor's own memory at the start and the end of each run and the time it takes to reach a decision in the last hour against the first. Over three runs the memory ratio was 1.05 to 1.07 and the decision-time ratio 1.07 to 1.20, both inside the limits set before the run (a leak would show as steady growth; a brain that slows as its records accumulate would show a ratio climbing toward the 1.5 limit), and the cluster's service under the governed arm was inside the noise of native in two of three runs. The 24-hour runs on three rented machines, started as this is written, ask the same two questions over twelve times the window. A single controller that keeps its memory and its speed over a day is the least a referee should ask of a brain that proposes to hold every knob at once; the figures are in the table, not asserted here.

CHAPTER 33

The Nervous System in Detail

33.1 The two-way nervous system (live controller)

Source. Manuscript Appendix J: "Nervous system. The signal layer: sensing interfaces, unit integrity, timing coherence, delay and dropout handling, and feedback interpretation. … The brain cannot compensate for corrupted signals." Manuscript Section 5.3: the engine "projects forward state trajectories … and detects destabilization pressure before divergence."

The gap. Before this change, the live controller fed the engine's `stale` (signal dropout) and `drift_ratio` (actuation mismatch) channels with a constant 0. So the upward path could not report a blind sense, and the downward path never learned whether its orders landed.

33.1.1 Upward: afferent integrity (senses to engine)

Every declared sense reports whether it is live.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Latency.** Blind when its newest sample is older than two windows by the wall clock, or when the window holds no successful request.
  - A hung probe freezes its file; its last clean window must never be read as the present.
  - Failed requests inside a live window become latency pressure (the failed share), so a failure is never read as silence.
- **Power.** Blind when its command returns no number.

How blindness is used.

- The blind share enters the engine as `stale`. It raises E, lowers U and feeds the external bath (equations 1-3 via `assimilate`).
- The nervous system grants no contraction on a blind sense, to any organ, and admits no held batch work.
- Expansion and batch pause (the protective directions) stay allowed.

33.1.2 Downward and back: efferent feedback (proprioception)

Every command is recorded.

- The node count commanded.
- The HPA targets written.

At the next decision the observed state is read back. For each organ, `drift = |observed - commanded| / commanded`.

- The largest drift enters the engine as `drift_ratio`. It raises E and I_U, lowers U and feeds B (equations 1-3).
- The node organ may not be given a new release while its last command did not land. For example, a drain refused by the PodDisruptionBudget leaves the node in service, and the next decision sees it.

33.1.3 Sideways: attribution (organ to organ)

The machine organ has its own engine view, fed with machine-attributable pressure only (pods waiting for a place).

It releases a machine only when all of these hold:

- pods are not scaling up and latency is not breached;
- nothing is pending;
- after the release the remaining machines stay at or below the engine's rho;
- its own calm, stress and security gates grant contraction;
- every sense is live;
- its last command landed.

All patents, copyrights and trademarks filed in the USA.

33.1.4 Tests (all in `verify.py`)

Test	What it checks
`tests/test_two_way.py`	blind senses (about 75,000 random states), frozen-probe detection, failures read as pressure, release refused while blind or after an order that did not land
`tests/test_node_release_gate.py`	the release gate, over 200,000 states
`tests/test_nervous_system.py`	the original invariants N1-N6, over 300,000 states

Every live decision records the senses, their ages, the proprioceptive drift and the gate's reason in the audit, and the benchmark prints them in the job log.

33.2 Nervous system

Omni-Compass is one field. Muscles are nerves.

```
telemetry  ->  afferent (per muscle)
           ->  one six-state engine
           ->  reflex (shield)
           ->  efferent (only WIRED + authority + not killed)
           ->  native controller on kill
```

`omnicompass/nervous.py` is the register. It does not invent GPU or chiller physics.

Status	Meaning
wired	this tree can sense and push
sensed	this tree can sense; it does not push
open	named, no plant, no push

Wired today: `nodes`, `hpa`, `power_cap`. Sensed: `heat`, `network`, `security`. Open: GPU, cooling, grid, queues, agents, … Never a muscle: value alignment.

```
python k8s_controlplane/test_nervous.py
```

PART FOUR

The Body: Muscles, Realms and Organisms

One thousand one hundred and seven muscles in four realms on one spine, built into seven organisms, and every gauge used to judge them.

CHAPTER 34

The Muscles, the Realms and the Seven Organisms

34.1 The catalog

The catalog of Omni v5 (`realms/catalog_v5.csv`) lists **1,107 distinct muscles in 70 families** (v2 and v3 listed 945 in 59, `realms/catalog.csv`, frozen for their results; v1 listed 656 in 46), each with its family, its plant model and its knob. A muscle is anything with a meter and a setting: a compute pool and its machine count, a GPU and its clock ceiling, a chiller and its setpoint, a battery and its reserve, a feeder and its tap, a robot joint and its speed limit, a pump and its flow. Each muscle carries a declared plant model, the simplest physics that reproduces how its meter follows its knob, and a native controller of its own, which is what the muscle does when Omni-Compass is not there. The catalog was built in four waves (`docs/realm_study/`): the spine from primary specifications, each realm's extras from its own specifications, a cross-check against industry and open-source controllers, and a verification, de-duplication and mapping pass. The register (`docs/REGISTER.md`, section 1) lists every family with its muscle count and the kinds of knob it carries, so a reader can see at a glance what the modelled realms contain and what they do not.

The seventy families, by realm, are these. **Compute, AI and cloud** (twenty-seven): AI inference serving, AI training, blockchain and ledger nodes, CI/CD and build farms, cloud virtual machines and capacity, container resources, cross-cluster and edge placement, DPU and programmable IO, distributed cluster managers, game servers and real-time interaction, GPU fabric and RDMA, GPU hardware, HPC and distributed compute, host CPU and memory, Kubernetes dynamic device allocation, Kubernetes placement and scheduling, Kubernetes workload scaling (the largest family, 32 muscles), Linux kernel and operating-system control, media streaming, node fleets and Karpenter-class control, OpenShift and the Machine API, quantum computing control (modelled), serverless functions, virtualization and hypervisors, work admission and demand shaping,

All patents, copyrights and trademarks filed in the USA.

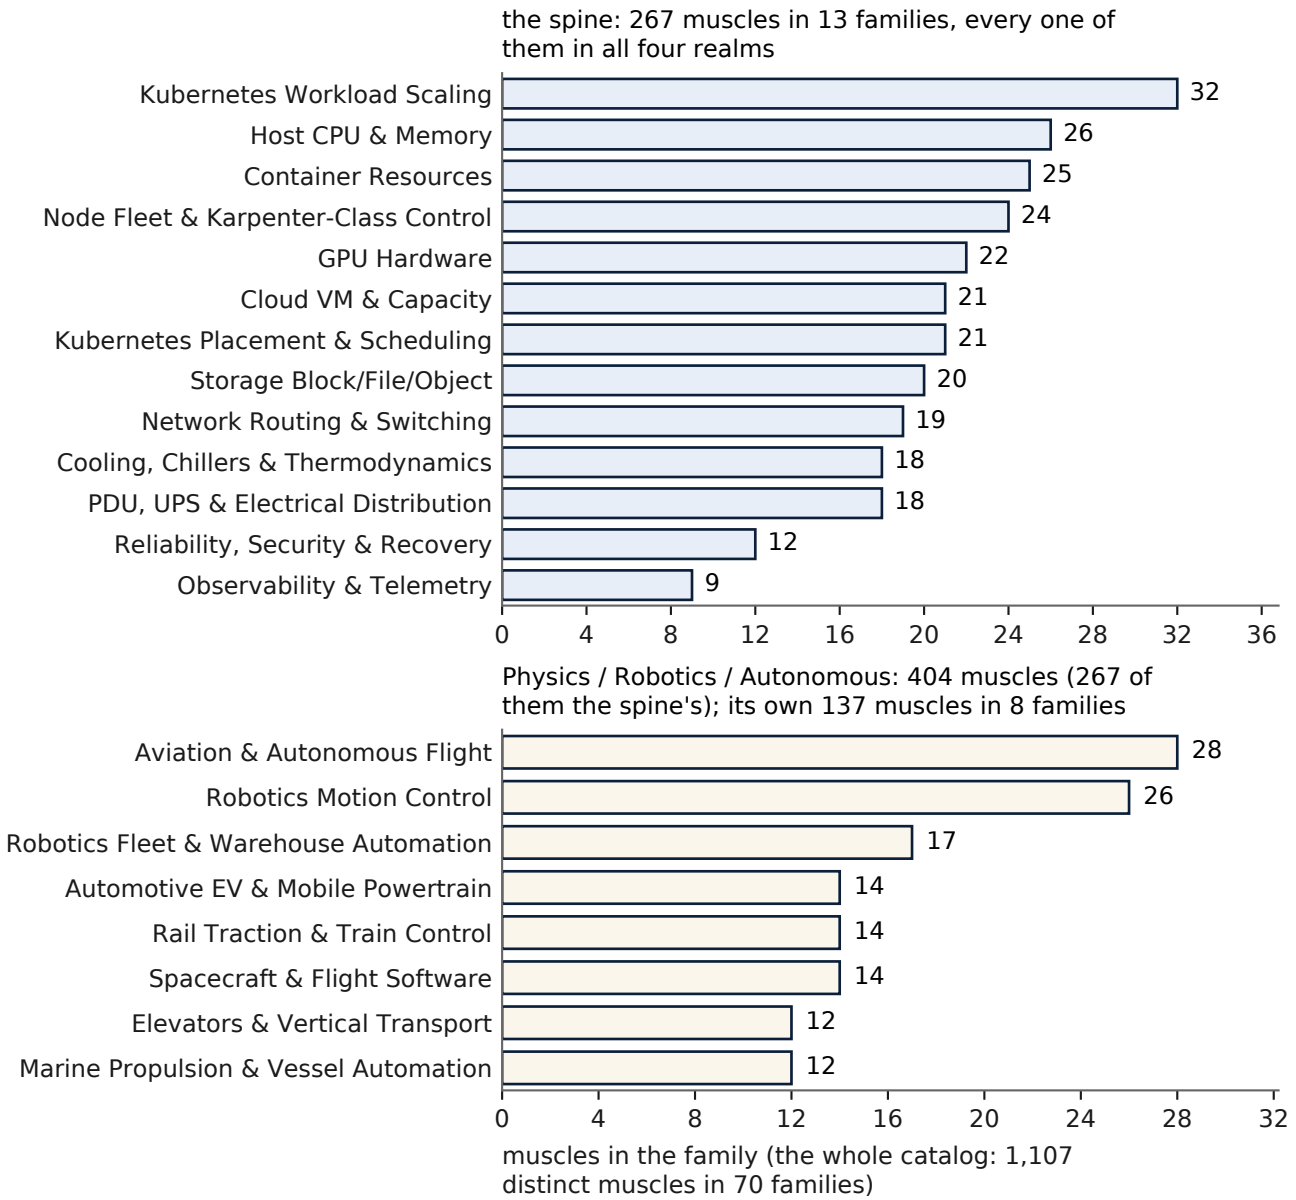

Figure 17. Grid: the families of the spine and of the Physics / Robotics / Autonomous realm, from realms/catalog_v5.csv. The spine's 267 muscles, every one of them in all four realms, in their 13 families; and the realm's own muscles, those it adds on the spine, in their families, by count.

and the body's gut (data-plane intake and waste) and skin (perimeter and admission). **Physics, robotics and autonomous** (eight): automotive EV and mobile powertrains, aviation and autonomous flight, elevators and vertical transport, marine propulsion and vessel automation, rail traction and train control, robotics fleets and warehouse automation, robotics motion control, and spacecraft and flight software. **Energy, facility and industrial** (seventeen): agriculture and irrigation, building and critical-environment HVAC, cooling and chillers, district heating and cooling, energy storage and microgrids, facility and grid optimisation, grid transmission and distribution, healthcare critical environments, industrial PLCs and process automation,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

mining and mineral processing, oil and gas pipelines, PDUs, UPS and electrical distribution, pharmaceutical and food manufacturing, power generation and turbine control, renewable generation and inverter control, semiconductor fabs and precision manufacturing, and water and wastewater pumping. **Distribution and specialized** (eighteen): cache and memory services, commerce and payments, content delivery and edge caches, data analytics and ETL, databases and transactions, financial markets and trading systems, medical imaging and clinical systems, messaging and streaming, network routing and switching, observability and telemetry, ports and maritime logistics, reliability, security and recovery, runtimes and applications, search, indexing and vector databases, service meshes and API reliability, block, file and object storage, telecom radio access and edge radio, and workflow, logistics and fulfilment. Thirteen of these, marked "v2" in the register (the elevators, marine, rail, agriculture, district heating, healthcare, mining, pipelines, pharmaceutical and food, power generation, renewable generation, medical imaging and ports families), came with the second engine version; they, with the muscles added to the families that already existed, are the difference between the 656 muscles in 46 families of v1 and the 945 in 59 of v2 and v3. Eleven more came with v5 (the Linux kernel, serverless, virtualization, content delivery, gut and skin families in a first wave; financial markets, media streaming, game servers, blockchain nodes and build farms in a second), with muscles added to families already there; the founder's nine open-source pieces (Kepler, Climatik, EAR, CruiseKube, Goldilocks, the Kubernetes power manager, PEAKS, adaptive GPU power capping and NVIDIA's platform power budget) came on 12 October as ten muscles in the families their knobs belong to (`docs/OMNI_V5.md`, `docs/THE_SEAT.md`). The GPU family is named for the hardware, not one vendor.

Every muscle its own card. The brain is one, but since 13 October its settings are each muscle's own. A muscle's card holds the numbers the max uses for that muscle alone: how full a machine pool runs on its forecast before it calls for more and how many decisions of history it reads, how many wobbles of margin a battery keeps under its line and, for a battery wired by its power, how long it reads its line before it holds and how much of it it keeps clear. The cards were found by an automatic search over every muscle (`tools/tune_cards.py`), on development seeds only, today's global setting always one of the choices, and a card was kept only where it beat the global setting beyond the noise on two separate sets of seeds and was never behind native on any seed under any load (never over its line more often, never less work, never its line cleared later): 364 muscles carry one (`realms/muscle_cards_v5.csv`, every card in plain words in the muscle catalog, the evidence in `results/cards_v5/CARDS.md`); the rest run the global setting. Inside a body, a battery wired by its power keeps the body's own margins on its line, because the line carries the whole body's swing, which the card chosen for the battery alone never saw. The formal statement is *The Max, Formally* (`docs/FORMAL_V5.md`, section 5).

Every live benchmark in Part Seven sits inside one of these families: the Kubernetes tests inside workload scaling and node fleets, PostgreSQL and MySQL inside databases and transactions, Redis and MongoDB's cache inside cache and memory services, Kafka inside messaging and streaming, the robot arms inside robotics motion control, the drones inside aviation and autonomous flight, the power grids inside transmission and distribution, the buildings inside HVAC. A live result is therefore also a check on one family's model: where the real stack and the modelled muscle move the same way under the same law, the model has earned

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

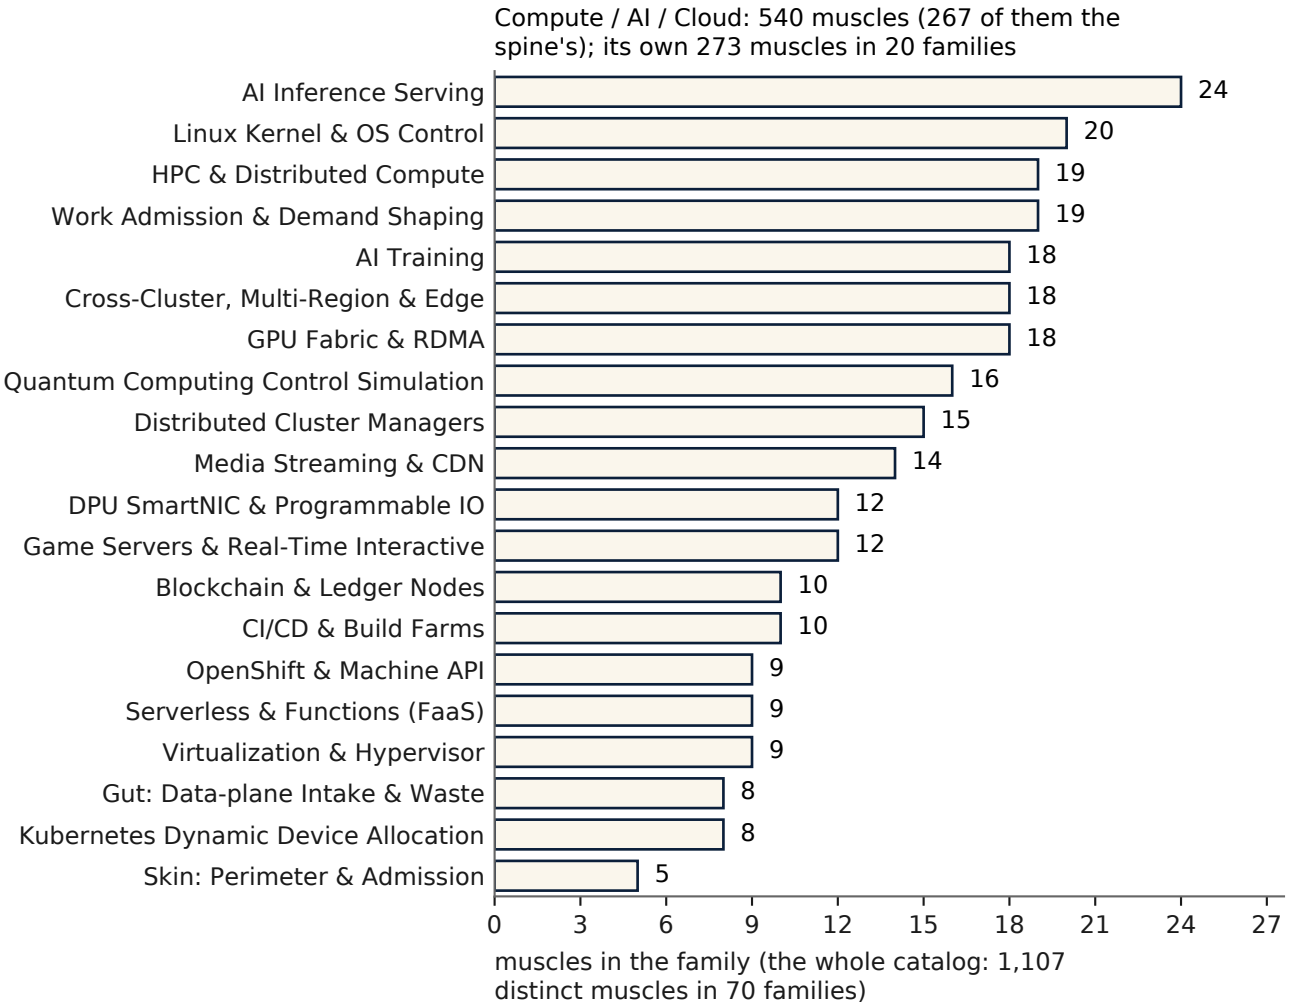

Figure 18. Grid: the families of the Compute / AI / Cloud realm, its own muscles on the spine, by count.

some trust; where they do not, the model is the thing to doubt, and the catalog's plant model for that family is the place to look.

34.2 The spine and the four realms

The muscles fall into four realms, and under every realm's own muscles stands the same **spine** of 267 muscles (Kubernetes workloads, containers, placement, node fleets, cloud capacity, hosts, GPUs, network, storage, observability, reliability and security, electrical distribution and cooling), because every realm's work runs on computers that must be scheduled, powered and cooled. Since 16 October the spine is an organism in its own right, the seventh, run native and with Omni-Compass on top like the other six: it is the base of every stack as an operating system is the base of every program, and a realm's reading beside the spine's shows what that realm's own trade adds to the base it stands on (the chapter *The Spine* follows this one). The catalog thus builds seven organisms, the spine first because the other six stand on it:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Organism	Muscles	What it is
The spine (`spine`)	267	the muscles every real stack runs on, every one in all four realms: clusters, containers, placement, node fleets, cloud capacity, hosts, GPUs, network, storage, observability, reliability and security, electrical distribution, cooling; an organism of its own, the base of the other six
1. Compute / AI / Cloud	540	clusters, GPUs, AI training and inference, cloud capacity, kernels, functions, media, games, ledgers, build farms
2. Physics / Robotics / Autonomous	404	joints, fleets, vehicles, flight and spacecraft axes
3. Energy / Facility / Industrial	480	data halls, buildings, batteries, UPS, process loops, feeders, hospitals, farms, pipelines, mines, district heat, power plants, renewables, pharmaceutical and food plants
4. Distribution / Specialized	484	networks, storage, databases, commerce, trading, content delivery, workflows, radio networks, clinical systems, ports
5. The four stacked, every duplicate kept	1,908	all four realms on one clock, the shared spine counted in each
6. The whole tower, every muscle once	1,107	every distinct muscle on one clock

These are the counts of the catalog that stands; earlier catalogs' counts stay with their own results in `docs/history/`.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

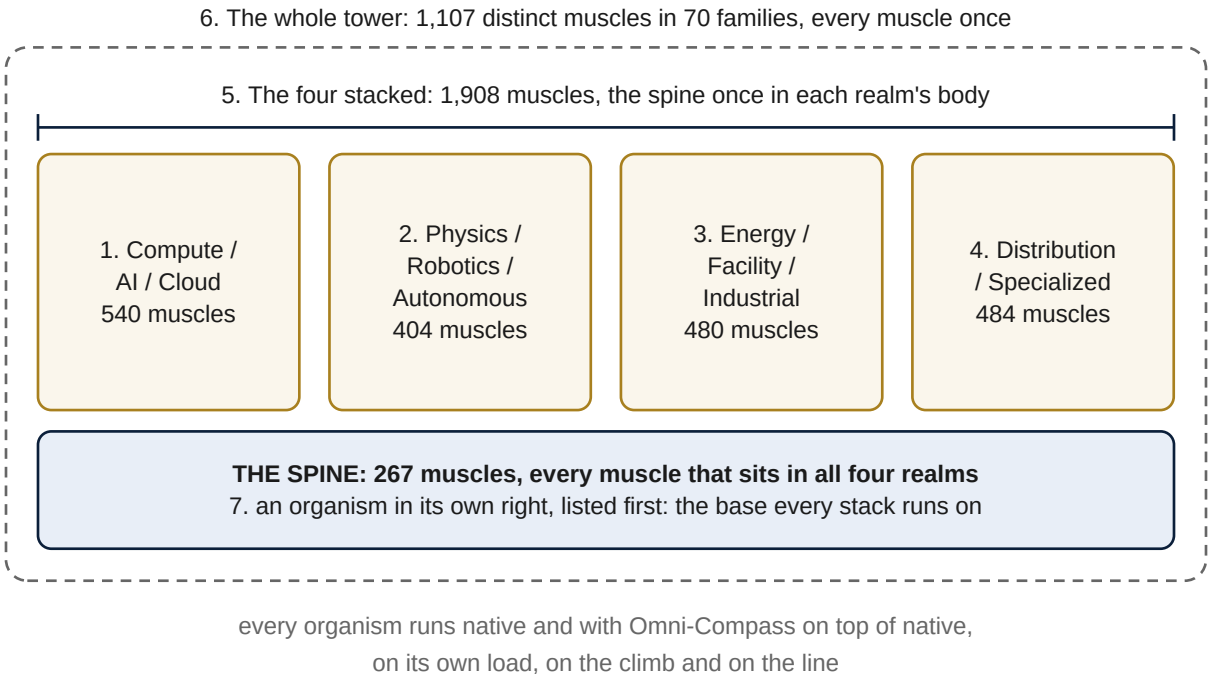

Figure 19. The seven organisms. The spine, the 267 muscles that sit in all four realms, is the base every stack runs on and an organism in its own right, listed first. The four realms stand on it; the four stacked count the spine once in each realm's body (1,908 muscles); the whole tower counts every distinct muscle once (1,107 in 70 families). Each organism runs native and with Omni-Compass on top of native.

The realms differ in what their domain muscles are and in how much slack their native controllers leave. Compute, AI and Cloud is clusters, cards, training and inference pools and cloud capacity, where the knobs are replica targets, machine counts, clock ceilings and power limits, and where native controllers are already good, so the modelled gains are small and the real gains come from the queue and the tail. Physics, Robotics and Autonomous is joints, fleets, vehicles, flight and spacecraft axes, where the knob is a speed or effort limit and the physics decides, axis by axis, whether spending slack as speed saves energy at all; this is the realm the v3 slack gate was written for. Energy, Facility and Industrial is data halls, buildings, batteries, UPS, process loops, feeders and plants, where the knobs are setpoints, units in service, reserves and taps, and where the muscles with the most room are also the ones whose reserves exist for a reason the model does not contain (a UPS held for an outage is never a lever). Distribution and Specialized is networks, storage, databases, commerce, workflows, radio networks, clinical systems and ports, where the knob is usually an admission, a pool or a replica count, and where the real stacks of this manual (the pooler, the broker, the cache) live. Every realm's list, by family and knob, is `docs/REALM_MUSCLES.md` and `docs/REGISTER.md` section 1.

All patents, copyrights and trademarks filed in the USA.

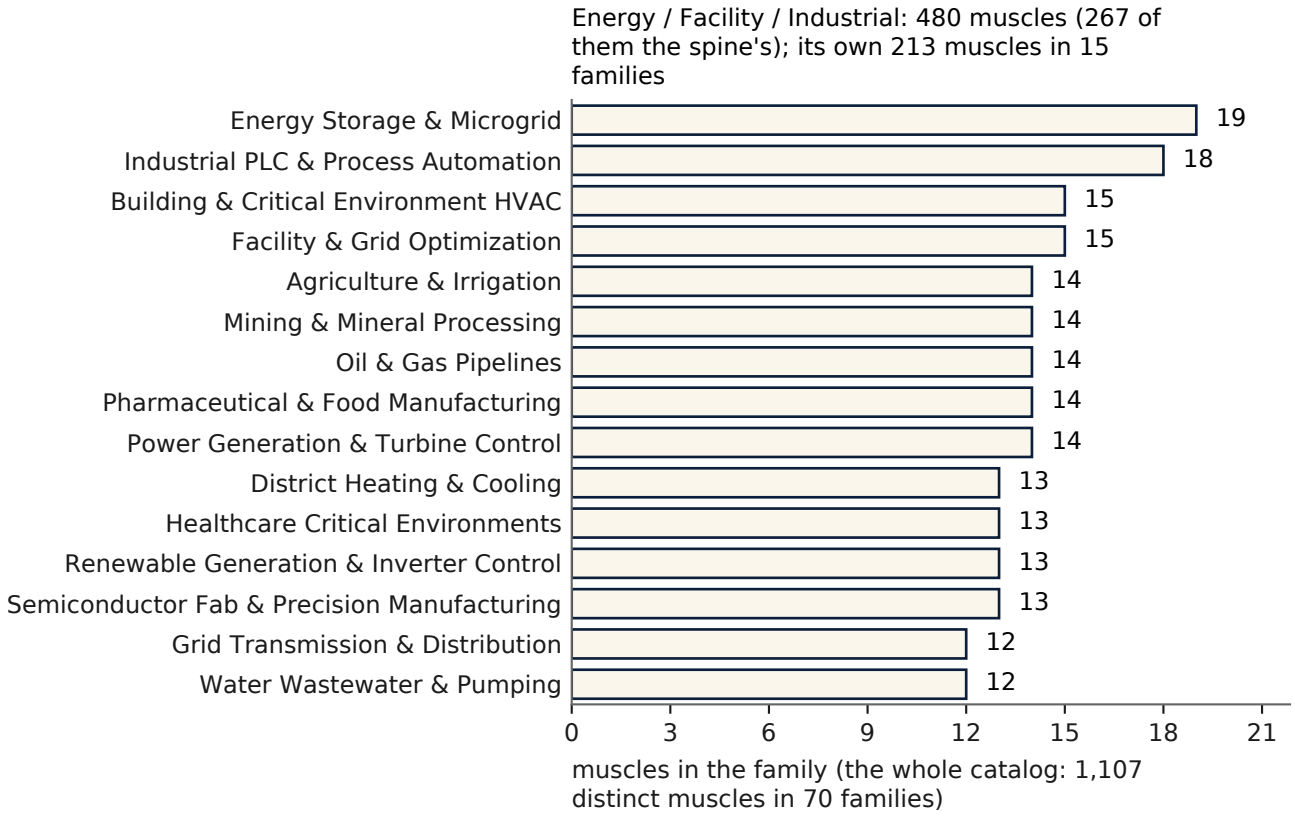

Figure 20. Grid: the families of the Energy / Facility / Industrial realm, its own muscles on the spine, by count.

34.3 What an organism run is

These seven organisms are the benchmark set of the modelled realms. An organism is every one of its muscles stepped on one clock, each from its own plant model, each with its own native controller, and the whole fed one demand trace from one seed. Native runs the organism with every native controller alone. Omni runs the same organism, the same seed, the same demand and the same clock, with the compass law on every knob the verdict allows. Each run produces its own receipt: the organism's work, its energy, its time over its service line, and every knob's hand-back. In code and in the workflows the whole-catalog organisms and the spine are named `tower`, `stack` and `spine`, never by a count, because a count changes with the catalog and a name that carried one would read as a different organism; the old names are read as aliases.

The receipt is read in a fixed order. **Work** first: the organism's output over the window, which must not fall, and which reads LOSS by rule if it does, however little, as the four stacked at 1,000 copies showed on a difference of one part in a million (section 34.5). **Energy** second, and **work per energy** with it, which is the gain the modelled realms are built to show. **Time over the service line** third, the share of steps on which any muscle's service reading was past its line, which is the do-no-harm gauge for the body as a whole. Then **every knob's hand-back**, which must be complete in every run or the run fails. The reading given to an organism (`results/realms_v5/REALMS_V5.md`, one table per engine) is GAIN, STEADY or LOSS by the key

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

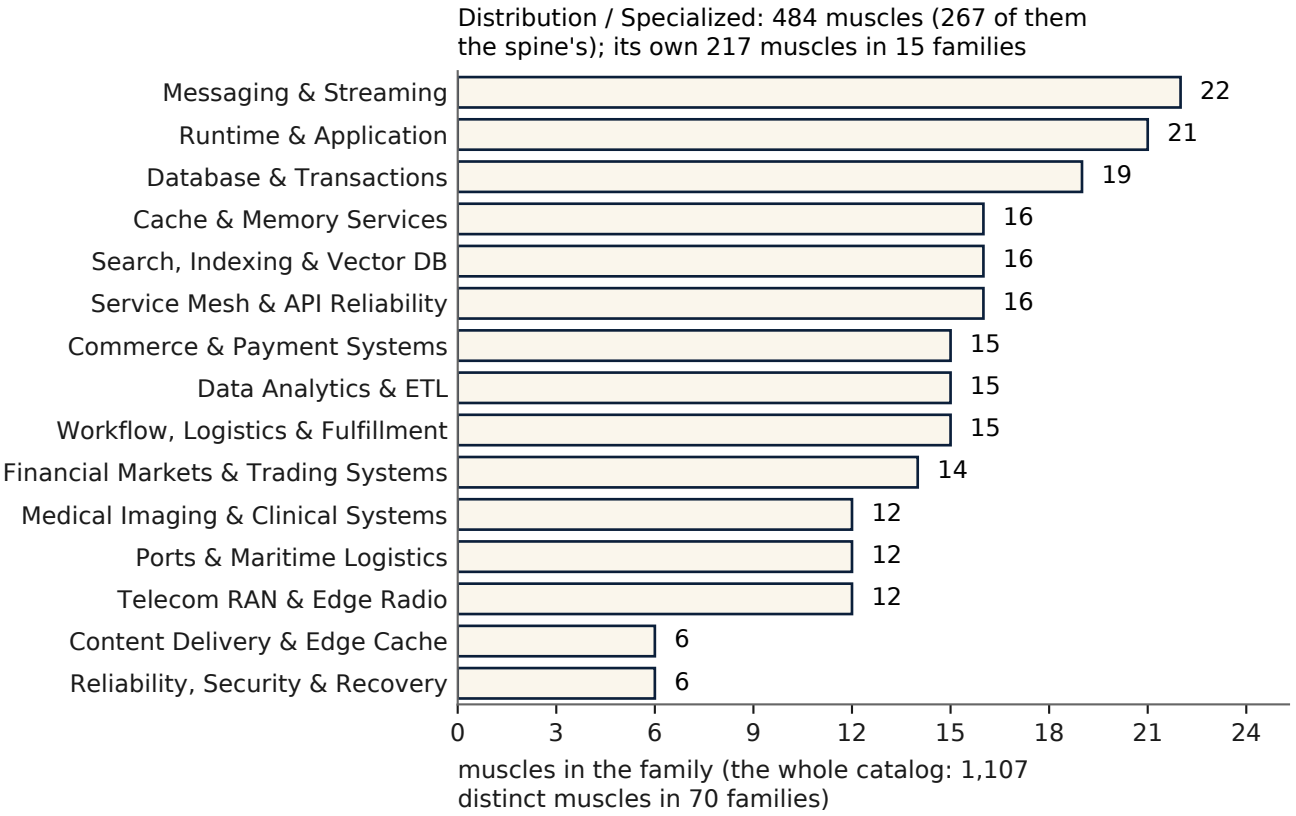

Figure 21. Grid: the families of the Distribution / Specialized realm, its own muscles on the spine, by count.

at the front of this manual: GAIN when its misses fell or its work rose beyond the noise and nothing moved the other way, STEADY inside the noise (the realms table was written before the rule of 24 October and is not among the tables read again by it), LOSS named where it stands; the energy the max took is power given, shown beside the work. Earlier engines' readings, and the words they used, are history (`docs/history/`). What an organism run cannot show is also fixed: it is evidence class S, the plant models are our own, and nothing in it is presented as proof of a real stack. Its use is to show that one law holds across every realm at once, at a size no live benchmark can reach, and to find the rules that then have to earn their place on real software.

34.4 The grid of copies and runs

Every organism runs at **1, 10 and 100 copies** (that many instances of the organism on one clock, so the four stacked at 100 copies is about 190,000 modelled muscles) and at **1, 10 and 100 paired runs** (that many native-and-omni pairs, each from its own seed): the seven organisms × three sizes × three run counts are 63 squares, run modelled and with the real cluster inside, both arms shown in every square. On GitHub's own machines the grid also runs the 1,000 tier, 1,000 copies and nested 1,000 runs (the founder's distinction of 15 October), a cell beyond a free runner's memory or time listed as pending runner capacity and never rented; paid cloud and GPU runs stay at 1, 10 and 100 copies with at most 100 repetitions (the founder's order of 12 October, kept for everything that costs money). Nothing is rented for the grid

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

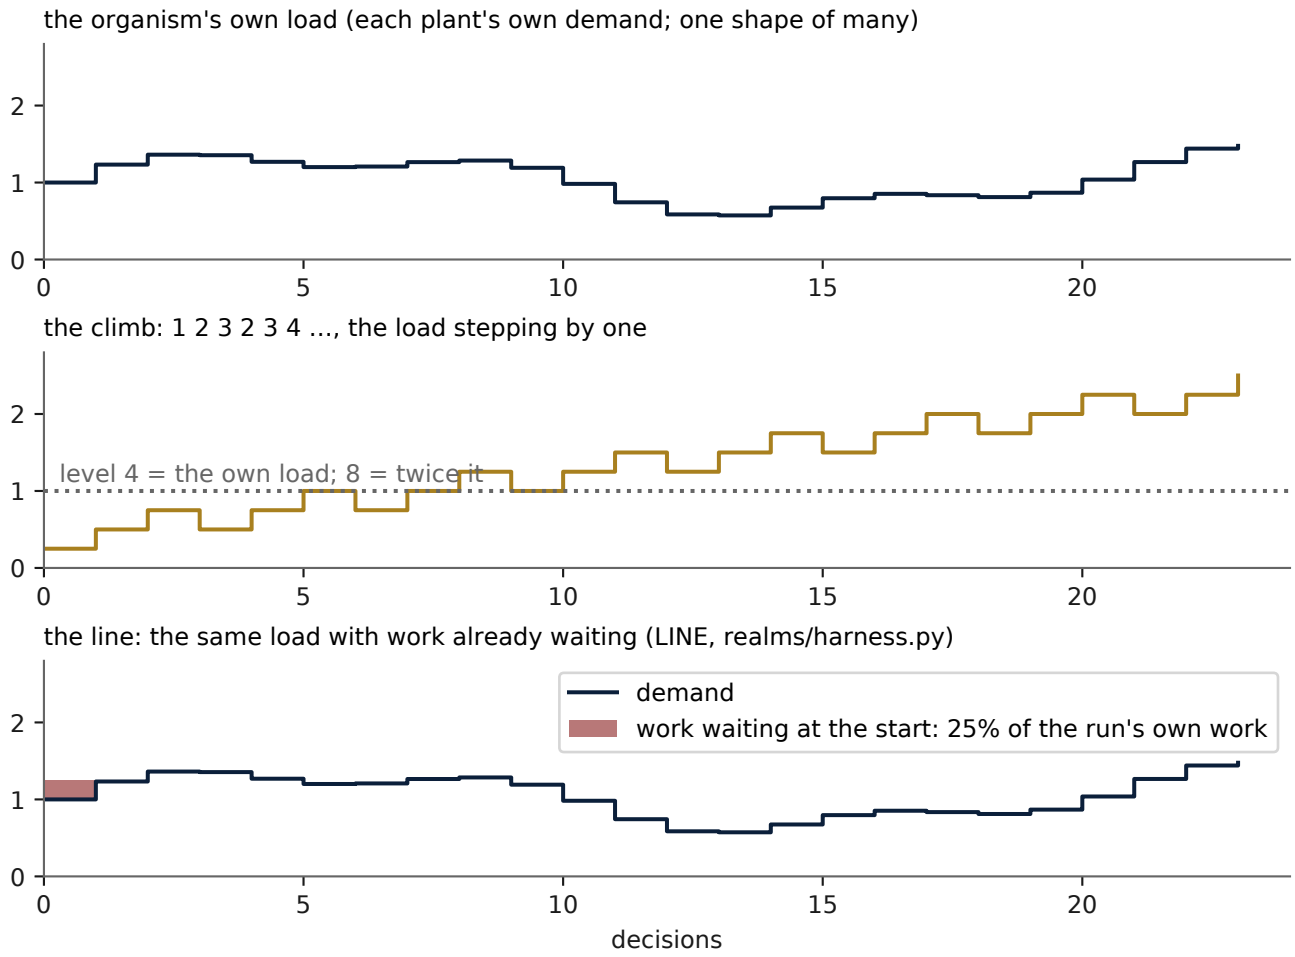

Figure 22. The three loads an organism runs under: its own load (each plant's own demand), the climb (the load stepping by one, 1 2 3 2 3 4 …, level 4 the own load and 8 twice it) and the line, the same load with a quarter of the run's own work already waiting when it starts.

(`scripts/dispatch_grid.py`, `results/grid_v5/`). Earlier engines' grids, which went to 1,000 copies and 1,000 runs, stand as they were run in their own pages (`results/scale/`) and are never read across engines.

The two axes answer two different questions, and a reader should keep them apart. **Copies** is the size of the body the one brain governs: at 100 copies of the four stacked, the law computes a force for about 190,000 muscles from one reading of one clock, and the question is whether it stays coherent, whether the decision time stays inside the decision period, and whether the cluster inside it (section 34.5) is still served on time. **Runs** is the number of independent paired trials, each from its own seed, and the question is statistical: how wide the interval of the paired difference is and whether it moves as the trials multiply. A square at 1 copy and 100 runs tells a reader about the noise of the method; a square at 100 copies and 1 run tells a reader about the scale of the brain; the squares on the diagonal tell both at once. Every square shows the native value and the omni value side by side, never a change alone, because a change without its two ends cannot be checked

the whole tower, 100 copies	1 run −0.038 pp	GAIN −0.037 pp	GAIN −0.037 pp

Figure 23. Grid chart: the seven organisms at every size and run count, modelled (class S), from results/grid_v5/GRID.md. Each cell is one square of the grid, copies × runs, with the change in misses against native and its reading: green GAIN, grey STEADY, red LOSS; a single run carries no label yet; the spine's squares are not yet in the receipt.

against the organism's own records. The grid is rebuilt whole on every engine version, never patched square by square, so that no square carries a result from a different engine than its neighbours (Chapter 59).

34.5 The organisms with a real cluster inside

The modelled organisms are also run with a **real Kubernetes cluster inside** as one more muscle (`tools/run_kil.py`, workflows `six-kube`, `big-organism`, `big-organism-detached`): the organism's own compute demand drives a real load generator against a real service on a real cluster, and the cluster's watts come back into the organism as heat and load. At 1, 10 and 100 copies this runs on GitHub's machines under protocol 4 (the organism's model on the runner's last core, the kind nodes on the others, the same in both arms; the window set from the heavier arm's step, timed before either arm; the served image pulled onto every worker before each arm, `docs/POD_START_WAIT.md`), and the whole tower and the four stacked at 100 copies also run on eight-core Azure machines, detached from the GitHub job that starts them. No 1,000-copy run is started from 12 October. These runs are evidence class L for the cluster and S for the organism around it, and are labelled "L + S".

Two rules keep these runs honest, and both are written in the preregistration before the run starts. The first is the **clock rule**. The organism must step on the measured window's clock: the row "organism behind its window" says how many seconds after the window its last step ended, and a repetition in which either arm ended more than 5% of the window late is marked **off the clock** in the organism's line, because its last steps saw a cluster whose load schedule had already ended. The row is shown and never judged; at 100 copies on the newest engine the tower's two arms ended 1.8 s and 2.4 s behind a 2,400 s window, a tenth of one percent, and no repetition was off the clock. The second is the **hand-back at 90%**. Omni-Compass releases the cluster's knob at nine tenths of the window and the last tenth is run by native alone in both arms, so that every repetition ends with the proof that the knob was given back and that native resumed where it would have been.

On omni-v5, the engine of its runs, the grid with the cluster inside (`results/grid_v5/GRID.md`, the card version, digest `5648f290`) reads the cluster's time over the response line and the organism's time over the line GAIN in every square of 10 and 100 repetitions; the organism's work per energy fell in 21 of those 36 squares, power given (it falls when more power is given; it bought fewer misses, not more work), and the cluster's 95th and 99th percentiles read LOSS in two squares at 100 copies, where the runner fell behind the organism's clock. Protocol 3 at 100 copies (digest `6093b2b8`, ten paired repetitions each; runs 38464343379, 38462289297, 38462280620) found the cause of those two: the tower's 95th percentile +47.7% and the four stacked's +87.2% (99th: +32.1%), on a four-core machine already about 80% busy and failing about half its requests in both arms, where the max added 40% to 54% replicas that nodes unable to grow could not carry; the four realms read STEADY on every response time. The fix, the replica muscle's live headroom read from the machines under it, belongs to the next version (`docs/omni_v5/NEXT_VERSION_PLAN.md`, section 3), and the eight-core Azure runs show how much of the LOSS the small machine carries. Earlier engines' runs at 1,000 copies on rented machines stand as they were run, in their own tables (`results/live/V1_BIG_ORGANISM.md`, `results/live/V3_BIG_ORGANISM.md`), and are not read across engines.

Figure 24. Grid chart: the seven organisms at every size and run count with the real Kubernetes cluster inside (the cluster class L, the organism class S), from results/grid_v5/GRID.md. Each cell counts the gauges that read GAIN and LOSS against native in that square; a square with a LOSS among its gauges is red, and it is looked into, never cut.

34.6 The register

The register (`docs/REGISTER.md`) is the one list a referee can audit: every muscle by family (Chapter 1), every benchmark by platform with its native controller, Omni-Compass's knob, its gauges, its result and its file

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(Chapter 34), what is not measured yet, said plainly (Chapter 76), and every open benchmark still to run, in order, one or two at a time (Chapter 12). The program that takes each benchmark to its full size, with what each step costs, is `docs/PROOF_PROGRAM.md`. Every benchmark in this manual appears in the register under the same name.

A row in the register is read left to right as a sentence: the platform, the open benchmark used for it and who publishes that benchmark, the native controller Omni-Compass sits on top of, the knob it moves, the gauges it is judged on, and its state. The state is written in a small, repeated vocabulary so that a reader can scan the column: **queued** (in the audited queue, not yet preregistered), **preregistered and built** (the rules are frozen and the harness runs, no counted result yet), the smoke runs with what each one taught and what was changed before the counted runs, and **A, B, C done** with the three run numbers, the engine version and the readings, losses first where there are any. A row never loses its history: when a benchmark moves from smoke to counted, the smoke record stays in its preregistration, and when a result is superseded by a run on a later engine, the earlier table moves to `docs/history` with its engine named. The register is the only list that must be complete; the manual's Chapter 60 and the dossier (`docs/DOSSIER.md`) are readings of it, and anything in them that is not in the register is an error to be fixed in the register's favour.

The audited queue (Chapter 12 of the register) is the program's promise about what comes next, and it is deliberately short at the front: one or two benchmarks are run at a time, each preregistered, built, smoked and counted before the next is opened, so that no result is ever waiting on a harness that was half built when the runs began. The queue is ordered by what each benchmark adds to the index that the ones before it did not: a new resource traded (memory after machines, a buffer pool after a cache), a new native controller, a new class of evidence.

34.7 Ten organisms, two ways: the twenty scenarios

Beside the seven organisms of the catalog the repository reads three more, each a grouping of catalog rows or of real tables and none a product (`DISCLOSURES.md`, section 9): **the orchestra**, the muscles that stand for the knobs of the governors and orchestrators the founder named (55 muscles, `tools/run_orchestra.py`, the mapping in `tools/governors_page.py`); **the live engine's own organism**, the sixty muscles the live benchmark engine page draws (`docs/engine/export_harness_trace.py`); and **the whole organism** in its three pieces, the software end, the cloud's wire and the bare metal, composed from the real tables by the product law (`tools/whole_system.py`, section 60.6). Each of the ten is read two ways on the same seeds: native (every plant under its own native controller) and Omni-Compass on native (the max, the factory tune, on top of every native controller). Omni-Compass is never by itself (the founder's order of 25 October): it always sits on top of a native controller. Ten organisms by two ways are the twenty scenarios, written by `python3 tools/scenarios_20.py` into `results/scenarios/SCENARIOS_20.md`, class S, three runs (seeds 3000 to 3002), under the climb for the full hour of 240 decisions of 15 s; their readings are in section 60.10.

CHAPTER 35

The Spine: the Base Every Stack Runs On

The **spine** is the set of muscles every real stack runs on: the 267 muscles of the 1,107-muscle catalog (`realms/catalog_v5.csv`) whose realm list names all four realms. A robot fleet, a trading system, a hospital's critical environment and an AI training pool differ in every muscle of their own trade, and they are alike in this: their work runs on computers that are scheduled, placed, given processors and memory, connected, stored, watched, kept alive, powered and cooled. Those thirteen families are the spine. Since 16 October (the founder's order) the spine is an **organism in its own right**, the seventh, run native and with Omni-Compass on top of native exactly as the other six are, because the base of a stack deserves its own reading before any trade is put on it. The relation is the one between an operating system and the programs that run on it: no program re-implements scheduling, memory or the disk, it stands on the system that does them; no realm's trade muscles re-implement the cluster, the fleet, the power or the cooling, they stand on the spine.

35.1 What the spine is made of

Family	Muscles	Plant model	Native controller class	The knob
Kubernetes Workload Scaling	32	compute pool (server)	the pod autoscaler, KEDA, the operator's rightsizers	replicas, targets
Container Resources	25	compute pool (server)	the vertical autoscaler, the scheduler's requests and limits	capacity, admission
Kubernetes Placement & Scheduling	21	compute pool (server)	the scheduler, descheduler, topology and affinity rules	admission, capacity
Node Fleet & Karpenter-Class Control	24	compute pool (node)	the cluster autoscaler, Karpenter-class provisioners	machines
Cloud VM & Capacity	21	compute pool (node)	the cloud's own scaling sets and capacity reservations	machines
Host CPU & Memory	26	compute pool (CPU host)	the kernel's frequency governor, memory and cgroup controls	capacity, power

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Family	Muscles	Plant model	Native controller class	The knob
GPU Hardware	22	compute pool (GPU)	the card's firmware: clocks, power limit, partitioning	clock ceiling, power cap
Network Routing & Switching	19	compute pool (network)	routing, queueing and buffer controls	capacity, admission
Storage Block/File/Object	20	compute pool (storage)	tiering, caching and throughput controls	capacity, admission
Observability & Telemetry	9	compute pool (server)	sampling, retention and scrape controls	admission
Reliability, Security & Recovery	12	compute pool (server)	disruption budgets, recovery and admission controls	admission
PDU, UPS & Electrical Distribution	18	energy storage (UPS)	the UPS and PDU controllers, their reserves and line limits	power, setpoint
Cooling, Chillers & Thermodynamics	18	thermal zone (data hall)	the chillers, air handlers and their setpoints	setpoint

Two hundred and sixty-seven muscles in thirteen families: 156 capacity knobs, 48 admission knobs, 35 power knobs and 28 setpoints. Every one is listed, with its knob, in `docs/REALM_MUSCLES.md` (the spine first), and explained, wired and carded in `docs/MUSCLE_CATALOG.md` (the manuals' muscle appendix, with every family's wiring recipe from `docs/wiring_recipes.csv`: the native controller, the wire out, the wire in, the restore, and whether the wire has run live in this repository or only on a model). The muscles of the spine's Kubernetes families are the ones the live Kubernetes benchmarks run on real clusters (evidence class L); the spine as an organism is modelled (class S), and nothing in it is presented as proof of a real stack.

35.2 Why the spine is an organism

An **organism** is a set of muscles stepped on one clock, each from its own plant model with its own native controller, the whole fed one demand from one seed, so that the heat the machines make is load on the rooms, the power swing of the body is load on every site's line, and one brain judges every step against every other muscle's cushion. Run alone, the spine is a data center with nothing of any one trade in it: clusters, fleets, processors, cards, network, storage, power and cooling, and the governor on top of their native controllers. Three readings come from it that the realms alone cannot give:

1. **The base before the trade.** Whether Omni-Compass helps the machines every stack runs on, before any realm's own muscles are put on them. A buyer wiring only a cluster and its site wires the spine and nothing else.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

2. **What a trade adds.** Each realm's organism is its own families on the spine. Read beside the spine's reading, a realm's reading shows what that realm's trade muscles add to, or take from, the base they stand on.
3. **The same base under four trades.** The four stacked carry the spine once in each realm's body, the tower carries it once in all. The spine run alone is the control for both: the same muscles, the same native controllers, no trade on top.

The spine is run under the same three loads as every organism (its own load; the climb, 1 2 3 2 3 4 …; work waiting in line), is judged by the same rule (work, speed and misses against native, the energy the max takes shown as power given), and has the same two arms and no other: **native**, every native controller alone, and **omni**, Omni-Compass on top of those same controllers, moving only the settings they expose, within their own ranges, and handing every setting back at the end.

35.3 How the spine is wired on a real stack

The spine is wired as any organism is: one governor per body, every shared resource a muscle or a gauge, a muscle with nothing to gain kept wired and watched (the Operator's Manual, chapter 2). The order is the order of the levels in the Operator's Manual, chapter 6, which is the order of the spine's own families: the cluster first (its workloads, then their resources and placement, then the machines under them), then the processors and the cards, then network and storage, then the site under all of them (electrical distribution and cooling), with observability and recovery wired from the first level, because the governor reads through them. Each family's wire is one row of `docs/wiring_recipes.csv`: which native controller owns the setting, where the reading is tapped, where the setting is written, and how it is restored. A realm's own muscles are wired after the spine they stand on, never instead of it.

35.4 The spine in the runners and the pages

The organisms are groupings of catalog rows made in the runners; no engine file names them, so the spine entered the runners without changing the engine that stands (`python3 tools/omni_version.py` prints the same fingerprint before and after). In every runner the spine is `spine`; in `tools/run_scale.py` and the grid conductor (`scripts/dispatch_grid.py`) it is organism `7`, after the six that were numbered before it, so that every grid run already started reads back under its own number. Every table lists the spine first, because the other six stand on it.

Where	The spine
`tools/run_realms_v5.py`	every muscle alone, then the seven organisms under three loads; the spine's row first in every organisms table (`results/realms_v5/REALMS_V5.md`)
`tools/run_scale.py --organisms 7`, workflow `six`	the spine at 1, 10, 100 and, on GitHub's own machines, 1,000 copies, over 1 to 1,000 paired runs

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Where	The spine
`tools/run_kil.py --organism spine`, workflows `six-kube`, `aks-metered`, `gke-metered`, `eks-metered`, `cloud-organism`	the spine with the real Kubernetes cluster inside it as one more muscle
`tools/run_hil.py`	the spine with the real card inside it (the GPU Hardware family is a spine family)
`scripts/dispatch_grid.py`	the spine's squares started, read back and never started twice like every other organism's
`docs/REALM_MUSCLES.md`, `docs/MUSCLE_CATALOG.md`	the spine's 267 muscles listed first; each muscle's organisms column names the spine
`results/realms_v5/`, `results/grid_v5/`, `docs/STATE_OF_PLAY.md`	the spine's readings, native against Omni-Compass on top, each named for the engine it ran on

CHAPTER 36

The Four Realms

The muscle tower on modelled plants: **1,107 distinct muscles in 70 families** (`realms/catalog_v5.csv`, the catalog the engine that stands carries), run as **seven organisms**, each native and with Omni-Compass on top of native: the **spine** (`spine`, the 267 muscles every real stack runs on, every one in all four realms; an organism of its own and the base of the other six, as an operating system is the base of every program: `docs/THE_SPINE.md`), each realm's organism (its own families on the spine: Compute / AI / Cloud 540, Physics / Robotics / Autonomous 404, Energy / Facility / Industrial 480, Distribution / Specialized 484), the four stacked on one clock with every duplicate of the spine kept (`stack`, 1,908) and the whole tower, every muscle once (`tower`, 1,107). Every muscle also runs alone on its own plant. Each is run natively (the plant's own controller alone) and with Omni-Compass on top, with meters and receipts, under three loads: the organism's own load, the climb (the load stepping by one, 1 2 3 2 3 4 …) and work waiting in line. Evidence class **S** (modelled: our own models of these machines, never counted in the headline and never presented as proof). The word "simulation" is not used for them; a live stack is class L, a meter class P.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

36.1 Run it

```
pip install -r requirements.txt
python3 tools/run_realms_v5.py --out realms5-out     # the preregister
    ↪ ed run: every muscle alone and the seven organisms, seeds 3000-3
    ↪ 009
python3 tests/test_realms.py                         # the harness's o
    ↪ wn checks (also inside verify.py)

python3 tools/realm_muscles.py                       # docs/REALM_MUSC
    ↪ LES.md: every organism written out, muscle by muscle
python3 tools/muscle_catalog.py                      # docs/MUSCLE_CAT
    ↪ ALOG.md: every muscle explained, wired and carded
```

The run is deterministic: `realms-v5.yml` (GitHub) runs it again and fails if any label or number differs from the table committed in `results/realms_v5/`.

Results, each named for the engine it ran on: `results/realms_v5/REALMS_V5.md` (the tables: every muscle alone over its loads, and the seven organisms under the normal, climb and line loads), `MUSCLES_V5.csv` (one row per muscle and load), `REALMS_V5.json` (every per-seed contrast), `RUN.json` and `SHA256SUMS.txt` (commit and fingerprints). The grid of copies and runs (1, 10 and 100 copies × 1, 10 and 100 runs, modelled and with the real cluster inside) is `results/grid_v5/GRID.md`. The earlier catalogs' results stay as the road to 1.0: v3's in `results/realms/`, v2's in `results/realms/v2/`, v1's in `results/realms/v1/`; nothing is read across engines, and every result runs again on the engine that stands (`scripts/reruns.txt`).

36.2 What is where

File	What it is
`realms/catalog_v5.csv`	the 1,107 muscles: family, name, realm, plant, parameter set, knob (v1's 656: `realms/catalog_v1.csv`; v2/v3's 945: `realms/catalog.csv`)
`realms/muscle_cards_v5.csv`	every muscle's own card: the factory setting it runs on, found on development seeds and kept only when it wins twice and never falls behind native on any seed
`docs/wiring_recipes.csv`	every family's wiring on a real stack: the native controller, the wire out, the wire in, the restore, run live or modelled
`realms/plants.py`	the five plants and their native controllers; the four knobs; the capacity law for one plant
`realms/presets.py`	every parameter, one set per family class

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

File	What it is
`realms/compass_arm_v5.py`	the law on every muscle at its default, the max, and the dial's tune-down (`V5CFG`, `V5SAVE`)
`realms/harness.py`	the arms (native, omni), the organisms, the three loads, the outcome and the label rule
`docs/REALMS_PREREGISTRATION.md`	the question, the rules, the seeds and the development history, frozen before the run
`docs/THE_SPINE.md`	the spine, the seventh organism: what it is, why it is an organism, how it is wired, where it stands in the runners
`docs/REALM_MUSCLES.md`, `docs/MUSCLE_CATALOG.md`	every organism written out muscle by muscle, the spine first; every muscle explained, wired and carded (the manuals' appendix)

36.3 How it relates to the rest

Layer	Realm harness	Elsewhere in this repository
Mathematics (T, V)	uses the engine and governor unchanged	`docs/TRACKING_THEOREM.md`, `verify.py`
Modelled (S)	**this**	the fleet and cluster models, the GPU model, the independent simulators (robot arms, grids, districts, swarms)
Real software (L)	not here	real Kubernetes and the live stacks (`results/live/`, newest engine first on the benefit sheet, `docs/BENEFIT_SHEET.md`)
Physical (P)	not here	the card: every earlier card result is obsolete and runs again on rented cards at one named commit (`docs/GPU_PREREGISTRATION.md`)

A realm result that reads GAIN is a reason to test that knob on a real machine, not a substitute for it. The realms whose knobs can be tested for real first are the compute realm's (Kubernetes on kind, the card), because the tools already exist.

CHAPTER 37

The Realm Muscles

Generated from `realms/catalog_v5.csv` (the catalog the engine that stands carries: 1,107 distinct muscles in 70 families) by `tools/realm_muscles.py`. A **muscle** is one setting on one machine that already has its own control; the one knob Omni-Compass may hold on it stands in brackets after its name. The catalog builds **seven organisms**, each run native and with Omni-Compass on top of native: the **spine**, the muscles every real stack runs on, an organism of its own and the base of the other six (as an operating system is the base of every program; `docs/THE_SPINE.md`); the four realms, each its own families with the spine under them, so the realm counts add to more than the tower; the four stacked; and the whole tower. What the engine does with each knob, which native controller owns it, where the reading is tapped and the setting written, how it is restored and its own card are written family by family in `docs/MUSCLE_CATALOG.md` (the manuals' muscle appendix); the organisms' results are in `results/realms_v5/REALMS_V5.md` and the grid in `results/grid_v5/GRID.md`, each named for the engine it ran on.

37.1 The seven organisms

In the runners the spine is `spine` (organism 7 in `tools/run_scale.py` and the grid conductor, after the six that were numbered before it); every table lists it first, because the other six stand on it.

Organism	Runner name	Muscles	What it is
The spine	`spine` (7)	267	the muscles every real stack runs on, every one in all four realms: the base of the other six
Compute / AI / Cloud	`compute_ai_cloud` (1)	540	its 273 own muscles on the spine of 267
Physics / Robotics / Autonomous	`physics_robotics_autonomous` (2)	404	its 137 own muscles on the spine of 267
Energy / Facility / Industrial	`energy_facility_industrial` (3)	480	its 213 own muscles on the spine of 267
Distribution / Specialized	`distribution_specialized` (4)	484	its 217 own muscles on the spine of 267

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Organism	Runner name	Muscles	What it is
The four stacked	`stack` (5)	1,908	the four realms' organisms on one clock, every duplicate of the spine kept
The whole tower	`tower` (6)	1,107	every muscle of the catalog once

37.2 The 1,107 muscles in the four realms they live in, heaviest hitter first

Heaviest hitters first (the founder's order of 1 November): every list of the muscles is ordered by what Omni-Compass did for each muscle against native in the record of every muscle alone (`results/realms_v5/REALMS_V5.json`; our own models, evidence class S; omni-v8, run 2026-10-17 15:39 UTC, 10 seeds, both loads). First the muscles that take decisions back under their line, the largest share of all their decisions first (a decision over the line is a muscle past its own limit, the first harm do no harm names); then the muscles that clear the work waiting in line sooner, the most first; then the muscles that only add work; then the muscles the same as native; last the muscles at their limit on native, where Omni-Compass writes nothing; equal hits by the catalog's number. The four lists are the four realms, each muscle under its home realm, every muscle once (`tools/heavy_hitters.py`).

Each realm below lists its home muscles, every muscle once, heaviest hitter first and down to its last; a muscle of the spine (it sits in all four realms) is listed under its home realm and marked (spine). Each name is followed by its rank in its realm and the one knob Omni-Compass may hold on it, in brackets.

37.2.1 Compute / AI / Cloud: 444 muscles, heaviest hitter first

37.3 The spine: 267 muscles, in all four realms, an organism of its own, heaviest hitter first

The thirteen families of the spine are the computers every realm's work runs on and the power and cooling they need: Kubernetes workloads, containers, placement, node fleets, cloud capacity, hosts, GPUs, network, storage, observability, reliability and security, electrical distribution and cooling. Run alone, the spine is a data center with nothing of any one trade in it; under a realm, it is what that realm's own muscles stand on. Its muscles, heaviest hitter first:

37.8 Organism 5: the four stacked, every duplicate kept, 1,908 muscles

The four realms' organisms above, run on one clock as one body (`stack`; the older name `stack_1226` is read as an alias): every muscle listed under organisms 1 to 4, the spine counted once in each, 1,908 in all.

37.9 Organism 6: the whole tower, all 1,107 muscles once

Every muscle of the catalog once (`tower`; the older name `organism_656` is read as an alias): the spine and every realm's own families, 1,107 in all.

37.10 Organism 7: the spine, 267 muscles

The spine listed first above, run on its own (`spine`): the same muscles, the same native controllers, nothing of any one realm on top of them.

CHAPTER 38

The Domain Map

Every system Omni-Compass can sit on, what it reads, what it pushes, the reflexes that bound it, and where it stands.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

38.1 The connector pattern

Omni-Compass is the same engine on every muscle. Each muscle gets one connector with five parts:

Part	Role	Example (compute)
Afferent (sense)	What the muscle reports	load, pending work, power, heat
Engine	Equations (1)-(7) turn readings into state: error E, coherence U, pressure I[U], stress S, bath B	same six-state engine everywhere
Efferent (push)	The equation (2) law and allocation law drive the muscle toward convergence	node count, HPA target, power cap
Reflex (shield)	Hard limits checked before any push	never below pod requests, step limits, power limit
Kill	Control returns to the muscle's own controllers	restore HPA targets, observe only

Fit tiers used below:

- **Direct**: Omni can govern the muscle as a supervisory controller.
- **Supervisory**: Omni governs budgets, schedules and envelopes; the muscle's own real-time controller stays in charge of fast inner loops.
- **Advisory**: regulated or safety-critical; Omni recommends until certified (IEC 61508, DO-178C, ISO 26262, medical and financial regulation).
- **Not Omni's problem**: a different kind of problem; stated so no one claims otherwise.

Status: **Wired** (in code, verified), **Partial**, **Open** (connector not yet built).

38.2 Digital infrastructure

Muscle	Reads	Pushes	Reflexes	Fit	Status
Compute nodes and node pools	load, pending pods, requests	node count, park or power off	request floor, step limit	Direct	**Wired**
Pods via HPA	utilisation, replicas	HPA target	bounds 50-95%	Direct	**Wired**
Power caps	watts, site limit	per-node caps	site power limit (I4)	Direct	**Wired** (harness)
Heat	temperatures	feeds decisions	thermal limit	Direct	**Sensed**

All patents, copyrights and trademarks filed in the USA.

Muscle	Reads	Pushes	Reflexes	Fit	Status
GPUs / accelerators	utilisation, power, temperature, memory	power caps, clocks, partitioning (MIG), packing	temperature, job safety	Direct	Open
CPU power states	per-socket power (RAPL)	frequency scaling, sleep states	latency floor	Direct	Open
Memory	used vs requested	request right-sizing	OOM margin	Direct	Open
Storage	I/O load, latency, capacity	tiering, placement, volume scaling	durability, replica counts	Super visory	Open
Network, load balancers	traffic, congestion, latency	routing weights, traffic shift	capacity per link	Direct	Partial
CDN / edge	cache hit, origin load	cache and origin routing	freshness	Direct	Open
Batch and HPC job queues	queue depth, deadlines	admission, priority, time shifting	deadline guarantees	Direct	Open
Multi-cluster / multi-region	load, cost, carbon per region	placement	data residency	Direct	Open
Deployments	release health	pause, roll back	never skip required checks	Direct	Partial (stack harness)
Databases, stateful services	load, replication lag	read replicas, pools	consistency limits	Super visory	Open
Control plane health	API latency, etcd load	rate of Omni's own actions	never overload the API	Direct	Open
Tenant quotas	usage per tenant	who may grow	fairness bounds	Direct	Open
Hardware health	disk and memory errors	early drain of failing machines	availability floor	Direct	Open
Observability pipelines	data volume, cost	sampling, retention	required audit data	Direct	Open
Security posture	policy blocks	block expansion during holds	I1	Direct	Partial (sensed)

All patents, copyrights and trademarks filed in the USA.

38.3 AI

Muscle	Reads	Pushes	Reflexes	Fit	Status
Training clusters	GPU power, progress, network	power caps, packing, checkpoint timing	never kill a run mid-step	Direct	Open (gpu vessels in harness)
Training power smoothing	synchronised power swings	ramp limits, staggering	grid ramp limits	Direct	Open
Inference serving	request rate, latency, queue, GPU memory	replicas, batch size, GPU sharing	latency SLO	Direct	Open
Model routing and cost	cost per request, quality signals	route to smaller or larger models, token budgets	quality floor	Direct	Open
Model releases	evaluation results, drift, errors	gate, pause, roll back a model	release gates	Direct	Open
Data pipelines, vector databases	backlog, freshness	scaling, scheduling	freshness bounds	Direct	Open
AI agents: containment	actions, spend, resources, network use	CPU, memory, network and spend caps, tool permissions	hard caps, instant kill	Direct	Open
Carbon-aware AI	grid price and carbon intensity	when and where training runs	deadlines	Direct	Open

38.3.1 AI alignment: what Omni can and cannot do

Alignment has two parts, and only one is Omni's.

Part	What it means	Omni's role
Value alignment	The model itself wants and does what people intend: honest, safe, helpful behaviour learned in training	**Not Omni's problem.** A governor outside the model cannot make the model's goals or judgement correct.
Control and containment	Whatever the model wants, it can only act within bounds: resources, permissions, spend, network reach, a kill that works	**Direct.** This is a governance problem: sense what the agent is doing, bound what it may spend and touch, revoke instantly, keep an audit trail.

Omni-Compass can be the boundary layer AI runs inside. It cannot be the thing that makes AI trustworthy. Claims must keep that line.

38.4 Facilities and energy

Muscle	Reads	Pushes	Reflexes	Fit	Status
Cooling plant	inlet temperatures, chiller load	setpoints, fan curves, chiller staging	inlet temperature limits	Direct	Open
Building HVAC	zone temperatures, occupancy	setpoints, schedules	comfort bounds	Direct	Open
Facility power distribution	PDU and UPS load	limits for the shield	breaker limits	Supervisory	Open
On-site batteries and generators	state of charge, grid state	charge and discharge	reserve floor	Supervisory	Open
Power grids: demand response	grid signals, prices	shift or shed flexible load	contractual limits	Direct	Open
Microgrids, renewable smoothing	generation, storage, load	dispatch	frequency and voltage limits	Advisory to supervisory	Open
EV charging fleets	vehicle needs, grid capacity	charge schedules	departure deadlines	Direct	Open
Water and pumping	demand, pressure, energy price	pump schedules	pressure limits	Supervisory	Open
Grid frequency and protection	frequency, faults	none	certified protection systems	Advisory	Out of scope for control

38.5 Physical operations

Muscle	Pushes	Fit
Manufacturing lines	scheduling, energy, throughput balance	Supervisory
Warehouses and logistics	task allocation, fleet charging	Direct
Robot fleets	task assignment, charging, traffic, safety envelopes	Supervisory (never joint-level control)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Muscle	Pushes	Fit
Traffic signals, transit, rail scheduling	timing and schedules	Advisory (safety-certified)
Ports, shipping	berth and crane scheduling, energy	Supervisory
Agriculture, greenhouses, irrigation	water and climate setpoints	Direct
Mining, oil and gas	energy and scheduling only	Advisory (process safety)
Semiconductor fabs	tool scheduling, energy	Supervisory

38.6 Science, space, biology, finance, health

Domain	What Omni could govern	What it must not touch	Fit
HPC / supercomputers	job queues, power, cooling	none beyond the facility	Direct
Quantum-computer facilities	cryogenics energy, calibration scheduling	qubit control	Supervisory
Satellites and constellations	power, thermal, data budgets, scheduling	attitude and orbit control (flight software)	Supervisory
Spacecraft / astrodynamics	mission resource budgets	guidance and navigation	Advisory
Biology: lab automation, bioreactors	setpoints, schedules, cold chain	living-system interventions without validated models	Supervisory
Financial markets	risk limits, exposure caps, trading infrastructure	making trades, market control	Advisory (regulated)
Hospitals	bed, staffing and energy operations	medical devices, treatment	Advisory
Aviation, automotive, nuclear	monitoring	any direct control	Advisory (certification required)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

38.7 The problems everyone in computing has, and Omni's fit

Problem	What Omni can do	Fit
Data-centre energy growth	right-size, park, cap, shift work in time and place	Direct
Cloud cost overruns and idle capacity	consolidate, right-size, remove padding	Direct
GPU scarcity and low GPU utilisation	pack jobs, share GPUs, schedule by priority	Direct
Heat and cooling limits	govern IT load and cooling plant together	Direct
Grid connection limits for new data centres	power smoothing, demand response, stay under contracted power	Direct
Carbon reporting and reduction	carbon-aware placement and timing, measured energy	Direct
On-call burnout and alert fatigue	hold the levers people turn at night; fewer alerts, each one meaning something	Direct
Autoscalers fighting each other	single authority	Direct (shown in our own models, class S, never offered as proof)
Latency and SLO breaches under load	headroom governance, fast scheduling floor	Direct
Noisy neighbours, unfair tenants	quotas and growth permissions	Direct
Hardware failures	early drain on failure signs	Direct
Observability cost and data explosion	sampling and retention governance	Direct
Configuration drift	detect and gate, not rewrite configurations	Supervisory
Cold starts	pre-warming policy	Direct
Data egress costs	placement near data	Supervisory
Runaway AI agents and spend	caps, permissions, kill, audit	Direct

All patents, copyrights and trademarks filed in the USA.

Problem	What Omni can do	Fit
Security misconfiguration, supply-chain attacks	block risky expansion during holds	Partial (not a security scanner)
Model hallucination and bias	none	Not Omni's problem
AI value alignment	none	Not Omni's problem
Software bugs, technical debt, legacy migration	none	Not Omni's problem
Vendor lock-in	a single governor over mixed clouds	Supervisory

38.8 Order of wiring

1. Digital infrastructure: GPUs, CPU power states, memory, storage, network, job queues, multi-region.
2. Facilities and energy: cooling plant, power distribution, batteries, demand response.
3. AI: training power smoothing, inference serving, model routing, agent containment.
4. Physical operations, then science and space as supervisors.
5. Regulated domains as advisors, until certified.

Each connector follows the same path as compute: wired, benchmarked against today's controls, verified, pre-registered, tested on held-out scenarios, then released.

CHAPTER 39

The Problem Map

Method: the issue trackers of the projects that run the world's clusters (Kubernetes autoscaler, Karpenter, Kepler, Kueue, Volcano, Knative, KEDA, kubernetes/kubernetes), the public industry reports (Cast AI, Datadog, Uptime Institute, IEA) and recent papers (Meta Llama 3, AI-datacenter power stabilisation). Not all of GitHub: a targeted scan of where the money and the failures are. Status: **have** = in this repository and tested; **partial** = built but not proven live; **missing** = not built.

#	Problem (evidence)	Size	Best tool today and its gap	Omni-Compass fit	Status
1	**Idle capacity.** Average Kubernetes CPU utilisation 8%,	largest money leak in cloud	Karpenter, Cluster Autoscaler, CAST AI: each fixes nodes only	one authority over replicas, requests, nodes and power	**built** (omnilab/right size.py, held-out)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Problem (evidence)	Size	Best tool today and its gap	Omni-Compass fit	Status
	memory 20%, falling; CPU over-provisioning 69%, memory 79% (Cast AI 2026). 83% of container cost goes to idle resources (Datadog)				
2	**HPA and VPA cannot be used together on CPU/memory**, "not compatible by design" (kubernetes /autoscaler #1726, #2939, #6060, #6247; coordination asked again in #8493, 2025)	blocks right-sizing for most teams	none; official advice is "don't"	exactly what a single authority solves: one engine owns both numerator and denominator	**built** (omnilab/right size.py: HPA+VPA vs one authority, held-out)
3	**Karpenter consolidation churn**: nodes replaced every 5-10 minutes for 2-3 generations, busy nodes removed instead of empty ones, one shared timer (karpenter #1851, #1019, #2705, #3046; provider-aws #7146, #8868, #7356, #8536)	outages, wasted boots	Karpenter's own timers and budgets	engine-gated release (equation 2) plus dwell; C-throughput cut node churn 50% in simulation	built in simulation (AKS NAP = Karpenter arm, tuni ng/vendor_compare .py); live Karpenter opponent next

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

#	Problem (evidence)	Size	Best tool today and its gap	Omni-Compass fit	Status
4	**CPU limits throttle apps** (CFS quota), causing latency and even OOMs (kubernetes/kubernetes #67577, #97445)	latency tails	manual tuning, "remove limits" advice	power-cap muscle must watch latency; our first live run hit this exact problem	have; live runs 3-5 found and fixed the resize permission
5	**Cold starts / scale-from-zero latency** (knative/serving #4902, #14202, #9104; kedacore/http-add-on #219)	seconds of latency per edge	Knative activator, KEDA	pre-warming decided by the engine from its state (anticipation)	**built** (omnilab/coldstart.py, held-out)
6	**GPU utilisation ~5%** (Cast AI 2026); idle GPUs scattered across nodes (volcano #3948, kueue #5243)	the most expensive silicon idle	KAI Scheduler, HAMi, nvshare, Volcano binpack	GPU power-limit muscle (have, calibrated), packing and sharing (missing)	**built** (omnilab/gpupack.py, held-out) + power limit
7	**AI training power swings**: 50-75% of TDP in milliseconds per GPU, ramps over 1000 MW/s at gigawatt scale; operators impose power and ramp-rate limits (SemiAnalysis; Uptime; arXiv 2508.14318, 2606.04869)	grid-connection risk, equipment damage	batteries, fast PSUs, manual GPU power caps	"training power smoothing" muscle: ramp-rate limit through GPU power caps, the engine's bath state B is literally a damped oscillator	**built** (omnilab/powersmooth.py, held-out; basin-only arm recorded)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Problem (evidence)	Size	Best tool today and its gap	Omni-Compass fit	Status
8	**GPU failures and stragglers**: Llama 3, 419 interruptions in 54 days on 16K H100s, one every ~3 hours; 58.7% GPU-related; slow stragglers undetected (Meta; Lablup 2605.09370)	lost training time	Meta's internal tools, checkpointing	hardware-health muscle: sense straggling, drain early	**built** (omnilab/health.py, held-out)
9	**Outages**: 54% cost more than $100,000, 1 in 5 more than $1M; power causes 45% of incidents (Uptime 2025)	direct money	SRE runbooks, AIOps	recovery and physical-SLA results in simulation: recovery 58 to 17 min	have (sim)
10	**Cooling**: industry PUE stuck at ~1.54 for six years (Uptime 2025)	~35% overhead on every watt	DCIM, DeepMind cooling AI	heat afferent have; cooling-plant muscle	**built** (omnilab/cooling.py, held-out)
11	**Energy measurement in VMs is impossible**: no RAPL/IPMI in VMs, Kepler building a model server (kepler #2487, 2026)	nobody can prove savings in cloud VMs	Kepler estimators	same gap we hit	**built** (omnilab/vmenergy.py: meter-calibrated attribution, held-out)
12	**LLM inference autoscaling**: KV cache fills memory before compute; prefill vs decode need separate	latency and GPU cost	llm-d, KServe, custom	inference muscle: scale on KV-cache use and queue, not CPU	**built** (omnilab/inference.py, held-out)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Problem (evidence)	Size	Best tool today and its gap	Omni-Compass fit	Status
	scaling (vLLM, llm-d)				
13	**Runaway AI agents**: loops and recursive calls, ~$10,000 overnight examples (Dark Reading; sandbox guides)	cost and safety	per-tool caps, early kill-switch projects	agent-containment muscle: caps, kill, audit	**built** (omnilab/containment.py, held-out); live version next
14	**Human error**: failures to follow procedures rose 10 points (Uptime 2025)	outages	runbooks	fewer manual actions: pages and human interventions to zero in simulation	have (sim)

39.1 Results of the build pass (held-out seeds 90001-90030, 30 per muscle, code frozen by SHA first)

Omni-Compass against the strongest native tool in each muscle; + toward its aim, - away from its aim, = tie / not significant.

#	Muscle	Opponent (best native)	Toward its aim	Away from its aim	Tie / n.s.
1-2	right-sizing	VPA in-place + HPA	CPU -3%, memory -11%, p99 -99%, reversals -84%, SLO minutes -57%	p95 +15%, OOM kills (few)	work done
5	cold start	KEDA HTTP	p95 -75%, p99 -58%, delayed >1 s -71%, instance-hours -8%	cold-start count (x8)	
6	GPU packing	Volcano binpack	idle powered GPU-hours -20%, energy -2%	mean wait +16% (seconds)	p95 wait, jobs, fragmentation
7	training power	vendor floor, worst-day setting	burn -9%, throughput loss -44%, 1-s swing -6%	max ramp (inside the grid's limit)	0 grid violations both

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Muscle	Opponent (best native)	Toward its aim	Away from its aim	Tie / n.s.
8	GPU health	threshold detection	goodput +10%, lost GPU-h -20%, restarts -29%, straggler hours -99%		checkpoint overhead
10	cooling	outdoor-air reset	PUE -2%, cooling -13%, inlet violations -73%		max inlet
11	VM energy	host meter split by CPU	per-VM error -37%, worst VM -34%		total
12	LLM inference	KEDA on queue	TTFT p95 -18%, SLO breaches -58%, GPU-hours -19%, preemptions -56%		TPOT, TTFT p50
13	agent containment	static caps	rogue spend -96%, time to contain -99%, peak sub-agents -59%	false stops (0.6 -> ~2.7/day), honest work -7%	forbidden actions (0 both: RBAC)

Engine vs no-engine: in every muscle the omni_no_engine arm scores close to omni. The mapping from engine state to action carries most of the effect; the evolved dynamics add smoothing. The basin-only arm (power smoothing, the bath equation alone setting the draw) cut ramps 63% but did not hold the grid limit: the human-set limit is required.

39.2 What this says

- The problems with the most money behind them are **idle capacity (1)**, **HPA/VPA coordination (2)** and **GPU idleness (6)**. Problem 2 is the cleanest proof of Omni-Compass's thesis: the Kubernetes project itself says its two autoscalers cannot share a metric, because they fight. A single engine owning both is the answer the issue tracker keeps asking for.
- The problem with the most strategic weight is **AI training power swings (7)**: it is new, it threatens grid connections, and Omni-Compass's own equation (7) is a damped second-order bath, the natural controller for ramp limits.
- The problems we already hit ourselves (4, 11) are the same ones the industry has: good evidence the benchmark is real.

39.3 Build order proposed

1. Request right-sizing muscle (VPA role) under the same engine, benchmarked against HPA + VPA "in conflict".

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

2. Training power-smoothing muscle (GPU power-cap ramp limits) with a synthetic synchronized-training power trace.
3. GPU packing / fragmentation muscle (with stand-in-gpu-operator or KWOK on the live cluster).
4. Live Karpenter opponent (kwok provider) to test problem 3 head to head.
5. Inference muscle (KV-cache and queue driven), then hardware-health (straggler drain), then agent containment.

CHAPTER 40

The Seven Organisms and the Benchmark Grid

Omni-Compass is benchmarked on seven organisms, each run native and with Omni-Compass on top of native on the same seed, the same load and the same clock. An organism is a set of muscles stepped together on one clock, each muscle from its own plant model with its own native controller, the whole fed one demand from one seed, so that the heat the machines make is load on the rooms, the body's power swing is load on every site's line, and one brain judges every step against every other muscle's cushion. On the 1,107-muscle catalog the engine that stands carries (`realms/catalog_v5.csv`) the seven are: the **spine**, the 267 muscles every real stack runs on, every one in all four realms, an organism in its own right since 16 October

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

and the base of the other six, as an operating system is the base of every program (`docs/THE_SPINE.md`); the four realms, each its own trade's families on the spine, Compute / AI / Cloud (540 muscles), Physics / Robotics / Autonomous (404), Energy / Facility / Industrial (480) and Distribution / Specialized (484); the four stacked with every duplicate of the spine kept (1,908); and the whole tower with every muscle once (1,107). Earlier catalogs' organisms and counts stay with their own results in `docs/history/`.

Every organism runs under three loads: its own load; the climb, the demand stepping by one, up and down (1 2 3 2 3 4 …), past what native can carry, so that the most each arm can do shows; and work waiting in line when the run starts. Every receipt shows work, the time over the service line (misses), the energy the max took as power given beside the work it bought, wear, and whether every knob was handed back; the reading is GAIN, STEADY or LOSS by the key at the front of this manual, judged by what each gauge is for and never by the sign of its number. The spine read beside a realm shows what that realm's trade adds to the base it stands on; the spine read alone shows whether the governor helps the machines every stack runs on before any trade is put on them.

The grid. Each organism runs at 1, 10 and 100 copies of itself on one clock and at 1, 10 and 100 paired runs, modelled and with the real cluster inside, both arms shown in every square; on GitHub's own machines the 500 tier runs too (the ladder of the Python's 500-run Monte Carlo, the founder's order of 25 October), a cell beyond a free runner's memory or time listed as pending runner capacity and never rented, while paid cloud and GPU runs stay at 1, 10 and 100 copies with at most 100 repetitions. The two axes answer two questions. Copies is the size of the body one brain governs: at 100 copies of the four stacked the law computes a force for about 190,000 muscles from one reading of one clock, and the question is whether it stays coherent, whether the decision is made inside the decision period, and whether the cluster inside it is still served on time. Runs is the number of independent paired trials, each from its own seed, and the question is statistical: how wide the interval of the paired difference is and whether it moves as the trials multiply. The grid's readings on the engine that stands are `results/grid_v5/GRID.md` and the standing block of `docs/STATE_OF_PLAY.md`, every square shown, the spine's squares filled by the conductor as they land; the number is small because the native controllers in the models are well tuned and leave little room, it is real within the model, and it is never counted in the Omni index, which is made of real stacks only.

On a GPU machine the real card is wired into each organism as one more muscle of its GPU Hardware family, a spine family, so the card is in the spine and in every organism built on it; its own power meter and its requests are counted in the organism's receipt, kept apart from the modelled plants and also added to them. Real Kubernetes is benchmarked separately on real clusters, and it is also wired into the organisms as one more muscle (`tools/run_kil.py`): at 1, 10, 100 and, on GitHub's own machines, 1,000 copies, the organism's own compute demand drives a real load generator against a real service on a real cluster, and the cluster's watts come back into the organism as heat and load. Those runs are labelled "L + S": the cluster is live software, the organism around it a model.

The seven organisms are models (evidence class S). They show how the law behaves across hundreds of kinds of machine at once and whether its effect is stable as the count and the size grow. Real Kubernetes, the real

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

database, the real broker, the real cache and the real card are the anchors measured on real software and, for the card, a real meter; their results and their losses are in the manual's Chapter 60.

CHAPTER 41

The Metrics Catalog

Every gauge Omni-Compass produces, where it comes from, and what kind of number it is. Three kinds:

- **Measured**: read from a real system (a real Kubernetes cluster, a real GPU's own meter, a real wall plug).
- **Modelled**: computed by a simulation from declared physics or recorded traces. It shows the mechanism, not a measurement.
- **Internal**: Omni-Compass's own state and decisions, recorded in its audit log on every decision, live or simulated.

Every report says which kind each number is. A modelled number is never presented as a measured one.

41.1 Service: what the customer feels

Gauge	Unit	Where	Kind
Response time, mean / 95th / 99th percentile	ms	live Kubernetes (`tools/live_reps.py`), GPU bench (`tools/gpu_reps.py`), GPU sims	measured live; modelled in sims
Failed requests	%	live Kubernetes	measured
Alert minutes: whole minutes whose 95th percentile, failed requests counted over, was over the line (the babysitting tax)	min	live Kubernetes and the cloud (`tools/live_reps.py`)	measured
Requests served / not served	count	GPU bench, GPU sims	measured / modelled
Pod start wait, total and mean	s	live Kubernetes (API server creation-to-Ready)	measured
Pending pods	pod-minutes	live Kubernetes	measured

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Gauge	Unit	Where	Kind
Backlog (SLO breach) minutes	min	site and node exchange sims, stack benchmark	modelled
95th-percentile latency factor	×	site and node exchange sims	modelled
Availability, time healthy, recovery minutes, recovered	share, min	stack benchmark (`benchmarks/stack_benchmark.py`)	modelled
SLA violations (physical, total, backlog, power, heat)	share of time	stack benchmark	modelled

41.2 Work and capacity: what the operator gets for the money

Gauge	Unit	Where	Kind
Work per energy (served requests per kJ)	req/kJ	GPU bench (the preregistered primary outcome), GPU sims	measured / modelled
Work per wall energy (whole machine)	req/kJ	GPU bench with a smart plug (`tools/wall_meter.py`)	measured
Work served	work units	site and node exchange sims	modelled
Work per kWh	units/kWh	node exchange sim	modelled
Energy per served request	J	GPU bench	measured
Energy per core-hour	Wh	live Kubernetes	declared model
CPU used by the app	cores	live Kubernetes (`kubectl top`)	measured
Utilisation (used / allocatable)	share	live Kubernetes	measured
Replicas (HPA), mean	count	live Kubernetes	measured
Pods started	count	live Kubernetes	measured
Worker nodes in service, node-hours, idle node-hours	count, h	live Kubernetes, stack benchmark	measured / modelled

41.3 Energy and power: the bill and the building

Gauge	Unit	Where	Kind
GPU energy (the device's own `power.draw`, integrated)	J	GPU bench	measured

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Gauge	Unit	Where	Kind
GPU mean power	W	GPU bench, GPU sims	measured / modelled
CPU package energy (RAPL)	J	GPU bench, where the machine exposes RAPL	measured
Whole-machine energy at the wall	J	GPU bench with a smart plug	measured
Energy on kind	Wh	live Kubernetes	**declared model** (kind has no meter)
Energy	kWh	site, node exchange and stack sims	modelled
Peak power	kW	site and node exchange sims, stack benchmark	modelled
Site-budget violation minutes (time over the building's limit)	min	site and node exchange sims	modelled
GPU power limit, mean; power-limit writes	W, count	GPU bench, GPU sims	measured / modelled
Power-cap travel	share	stack benchmark	modelled

41.4 Hardware: heat and wear

Gauge	Unit	Where	Kind
GPU temperature, peak and mean	°C	GPU bench, GPU sims	measured / modelled
Heat-over minutes	min	hardware plant sim (`hardware/plant.py`)	modelled
Thermal travel	share	stack benchmark	modelled
Machine round trips, node starts and stops, scale reversals	count	stack benchmark	modelled

Lower power and fewer temperature swings are the conditions for longer hardware life. **No hardware life extension is claimed** until real temperature, duty-cycle and wear records exist.

41.5 Battery equivalent (derived)

A battery holds a fixed amount of energy, so battery life follows directly from work per energy:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- runtime on the same charge, for the same work: × (native energy ÷ Omni-Compass energy)
- work on the same charge: × (Omni-Compass work per energy ÷ native work per energy)

Example: the modelled GPU card at +5.1% work per kJ (`results/gpu/sim/after`) does 5.1% more work on one charge. The same rule turns any measured work-per-energy result into a battery figure. On-site battery banks as an organ of the power budget are designed (`docs/DOMAIN_MAP.md`, "on-site batteries") and not yet built.

41.6 Safety and control: proof it behaved

Gauge	Where	Kind
Writes executed per arm (native 0, watch 0, Omni-Compass n)	GPU bench, live Kubernetes	measured
Settings commands the governor wrote on its own, and the share of its additions decided while the service was still inside its line (the babysitting tax; no person touches either arm)	live Kubernetes and the cloud (`tools/live_reps.py`)	measured
Every arm ended at its start setting (the reset restored it)	GPU bench, live Kubernetes switch drill	measured
Invariant violations (all, and excluding power)	stack benchmark	modelled
Security violations, contradictions, pages	stack benchmark	modelled
Freeze check: code hashes at start and end (counted runs)	GPU bench (`FREEZE.json`, `FREEZE_END.json`)	measured
SHA-256 of every raw file	every live run	measured
The seal: every Python/C++ twin unchanged since proven equal	`results/SEAL.json`, `verify.py`	checked on every build

41.7 Internal: Omni-Compass's own state, on every decision (audit log)

Field	Meaning
`E, U, I_U, S, B, B_dot`	the six-state engine: energy, coherence (health), unmet-need integral, stress, redistribution, its rate
`state_observed`, `state_projected_next`, `prediction_error`	what the device said, what the engine projected, and how far off the last projection was
`requested_cap`, `granted_cap`, `shield_bound`, `want_w`	what the engine asked for, what the shield allowed, which bound decided it, the limit written

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Field	Meaning
`admissible`	whether the engine was permitted to change anything this decision
`speed_lock` (`ratios`, `line`, `aim`, `rate`)	the speed lock's reading against the run without Omni-Compass
`convey` engaged / released	when idle CPU is conveyed to serving pods, and when it is given back
`authority`: `calm` and its scalars (`kappa, h, sigma, nu`), `execute`, `contract` per organ, and the machine organ's own view	how settled the engine is, whether it may act at all, and which organs may give capacity back this decision (Kubernetes controller; `omnicompass/nervous_system.py`)
compass readings	the direction the engine reads the whole system to be moving (`omnicompass/compass.py`)
`write`, `would_write`, `why`	every command sent (or, in watch mode, withheld) and its reason
`snapshot`, `restored`	every setting read at start, and its read-back after the reset

41.8 Where each report lives

Report	Command	Output
Live Kubernetes, paired	`benchmark-reps.yml` (commit with `[reps]`)	`LIVE_REPS.md`, `results/live/`
GPU bench on a real card	`sudo bash scripts/gpu_paired.sh`	`results/gpu/run-*/GPU_REPS.md`
GPU physics sim	`python3 tools/gpu_physics_sim.py`	`results/gpu/sim/`
CPU-then-GPU speed lock sim	`python3 tools/gpu_pipeline_sim.py`	`results/gpu/sim/pipeline/`
Site power exchange (GPU groups)	`python3 hardware/site_exchange.py`	`results/hardware/SITE_EXCHANGE_*.json`
CPU + GPU on one budget	`python3 hardware/node_exchange.py`	`results/hardware/NODE_EXCHANGE_*.json`
Full stack benchmark and every check	`python3 verify.py`	`results/`, `VERIFICATION: PASS`

All patents, copyrights and trademarks filed in the USA.

PART FIVE

The Harness and the Wiring

The universal plug, the adapters, the wire check, and the step-by-step work of wiring Omni-Compass onto a running stack.

CHAPTER 42

The Plug, the Adapters and the Wire Check

Think of a high-end car stereo: one head unit, one standard plug on its back, and an adapter harness for each make of car that matches the car's factory plug. You never cut a factory wire, and when you pull the stereo, the car works as it did. Omni-Compass is wired the same way.

42.1 The plug (one design for every muscle)

Each plug has as many channels as its muscle has knobs. Every channel declares its cover (range), its direction (which way is "more"), its units and how fast it may move. Every plug keeps the same contract (`omnicompass/compass_law.py`, `Plug`):

1. **attach** - read the knob once, before any write: the snapshot. It never moves afterwards.
2. **read** - the service reading, into the compass.
3. **write** - one value, clipped to the cover, then read back from the device.
4. **one writer** - if the knob is found at a value Omni-Compass did not write, someone else owns it: Omni-Compass stops writing and leaves that value alone.
5. **restore** - on stop, the knob returns to the snapshot (where Omni-Compass found it, not the last value it wrote). For muscles whose native controller moves the knob itself, restore hands control back.

42.2 Adapters (one per standard plug)

Omni-Compass speaks each industry's standard control interface through an adapter. Status is stated plainly:

Standard	Muscles	Adapter status
Kubernetes API	HPAs, deployments, pods, nodes	**built** (`omni_controller/controller.py`, `muscles.py`)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

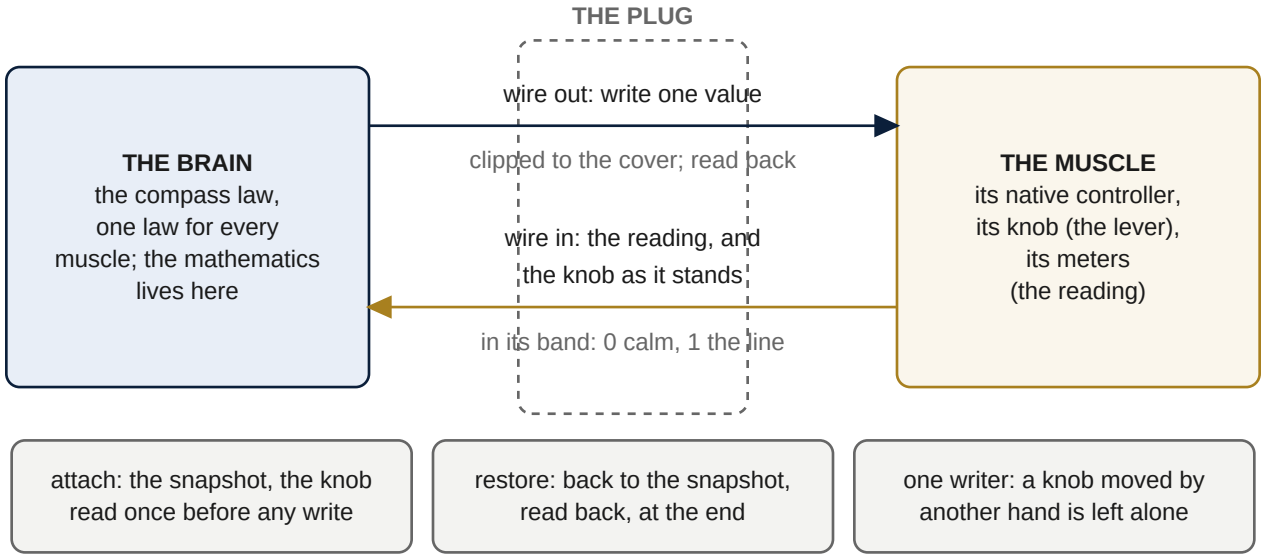

Figure 25. The two-way plug. One wire out carries the governor's write, one value per decision, clipped to the knob's cover and read back from the device; one wire in carries the muscle's reading, placed in its band, and the knob as it stands. The snapshot taken at attach, before any write, is the restore point, and a knob found where the governor did not put it belongs to another writer and is left alone. The brain holds the mathematics; the plug holds nothing but the contract.

Standard	Muscles	Adapter status
NVIDIA NVML / `nvidia-smi`	GPU clock ceiling, power limit	**built** (`omni_controller/gpu_compass.py`, two wires; `gpu_governor.py`, one wire)
Linux cpufreq, RAPL	CPU frequency ceiling, package watts	**built** (`--cpufreq-policy-root`, `--rapl-cmd`)
Site meter, building controller by command	site watts, supply-air setpoint	**built** (`--power-cmd`, `--cooling-cmd` command templates)
Cloud node groups (Karpenter, Cluster Autoscaler, MachineSet)	machines	**built** through `--node-scale-cmd` templates
Standard	**Muscles**	**Adapter status**
BACnet, Modbus, SNMP	chillers, air handlers, PDUs, UPS	designed; today reached through the command templates above

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Standard	Muscles	Adapter status
OPC UA, EtherNet/IP, PROFINET, EtherCAT, ROS 2, CAN	PLCs, drives, robots, vehicles	designed; modelled in the realm harness
IEC 61850, DNP3, OpenADR, IEEE 2030.5, SunSpec, OCPP	substations, batteries, inverters, chargers	designed; modelled in the realm harness

The engineer's job for one muscle is three things: which adapter, the address of the knob, and its safe range.

The plug contract, line by line, and why each line is there. *Attach* reads the knob once before any write and keeps that value as the snapshot. It is read once and never again, because a snapshot that moved with the knob would restore to wherever the governor last left it, and the whole point of the restore is to return to where the operator had it. *Read* takes the service reading (a response time, a temperature, a queue, an error) into the compass as a position in its band; the plug declares the band, the law does not guess it. *Write* takes one value, clips it to the cover before it leaves the plug, sends it through the muscle's own interface, and then reads the lever back from the device and records both the sent and the taken value; a device that took something other than what was sent (a clock that rounds to 15 MHz steps, a pool size the pooler capped) is recorded as it is, not as it was asked. *One writer* compares the lever as found at every read with the value last written; a lever found elsewhere has another owner, and the plug raises `ForeignWriter`, after which the governor leaves that lever alone for the rest of the run and says so in its audit and its exit code. *Restore* writes the snapshot back on stop and reads it back; a restore that does not read back is an error (exit 3), never a silent success. The same five lines are implemented for Kubernetes objects (annotations hold the snapshot on the object itself, so a watchdog can restore from the object without the governor's memory), for `nvidia-smi`, for PgBouncer's console, for Redis's `CONFIG SET`, for the consumer group and for the simulators' knobs, and `tests/test_*` prove each against a stand-in device.

42.3 Power-up order

Read-only first; then take the knobs, the least consequential first; on stop, hand them back in reverse order. In the Kubernetes controller the order is: the latency feed and the cluster's own metrics (read); the HPA target (a setting the HPA accepts and corrects within a minute); the pods' CPU limits (conveyance, in place); the machines (the slowest and most consequential, through the release gate and the verdict). On stop the machines are woken first, then the limits, then the target, so the cluster is never left with fewer machines than its pods need while a setting above them is still being handed back.

42.4 The wire check (mandatory before any write)

For the GPU it is one command, `sudo python3 tools/gpu_wire_check.py --gpu 0`, and `scripts/gpu_rented_run.sh` runs it first and stops if it fails:

Step	It proves
1 read	every meter answers: watts, temperature, utilization, limit, clock, top clock

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Step	It proves
2 snapshot	the start limit is recorded once
3 up wire	with the card busy, a ceiling below its own busy clock pulls the clock down under it; reset, the clock comes back above it
4 down wire	a lower power limit is reported back exactly; the start limit is reported back exactly
5 restore	clocks reset and the start limit read back
6 stop	the governor, stopped by its signal, hands both wires back
7 other writer	a limit set by someone else while the governor runs is left alone, and the governor exits 5

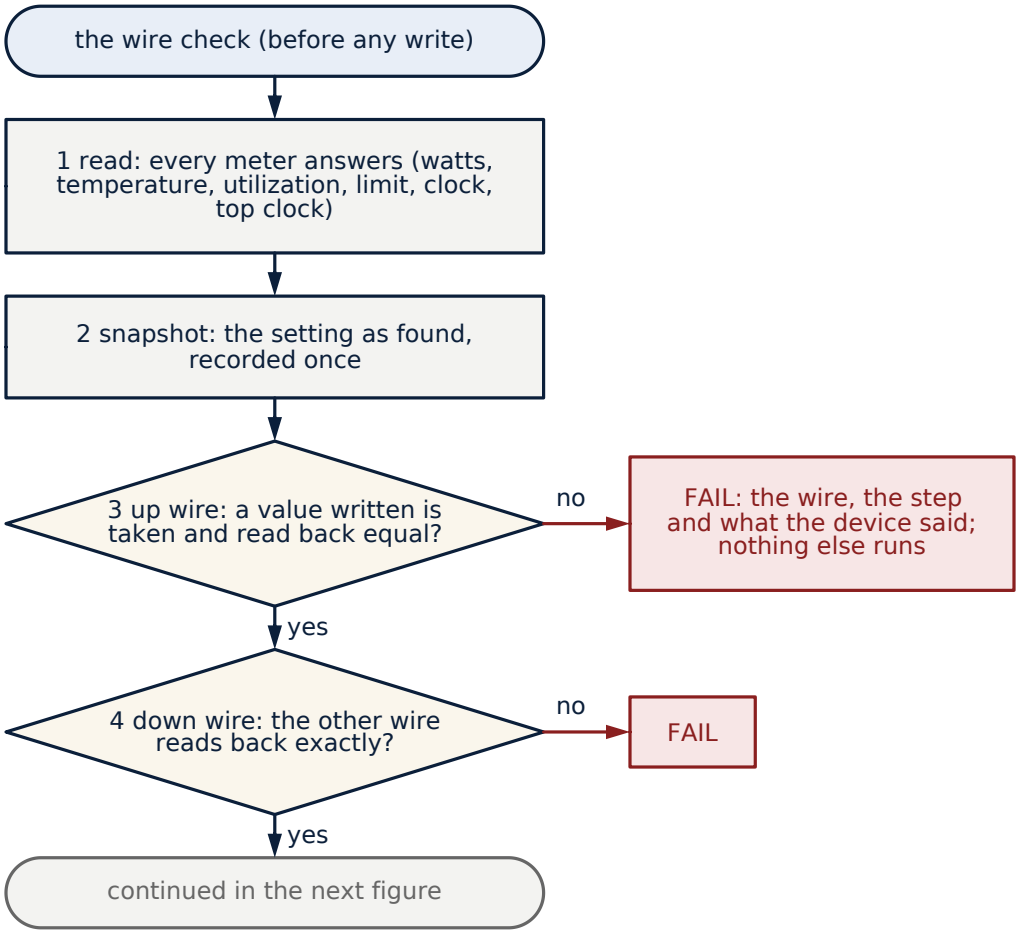

Figure 26. Flowchart: the wire check, steps 1 to 4. Before any write: every meter answers; the setting as found is recorded once as the snapshot; a value written on the up wire is taken and read back equal; the down wire reads back exactly. A step that fails stops everything with the wire, the step and what the device said; the chart continues in the next figure.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

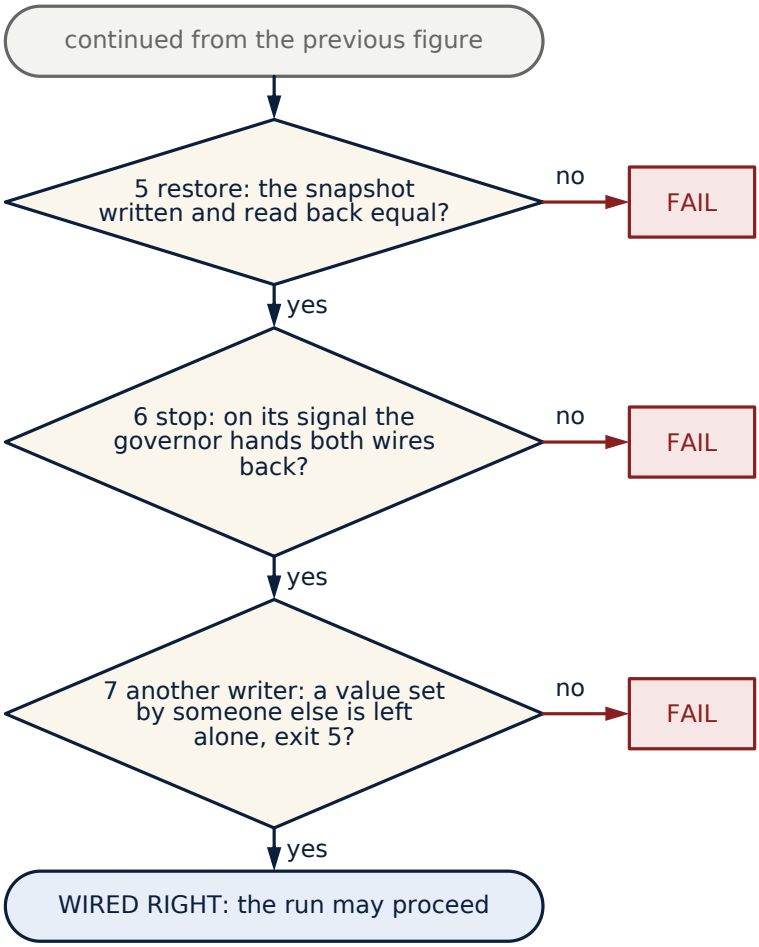

Figure 27. Flowchart: the wire check, steps 5 to 7 and the verdict. The snapshot written back reads back equal; on its stop signal the governor hands both wires back; a value set by someone else is left alone (exit 5). Only then is the muscle wired right and the run may proceed.

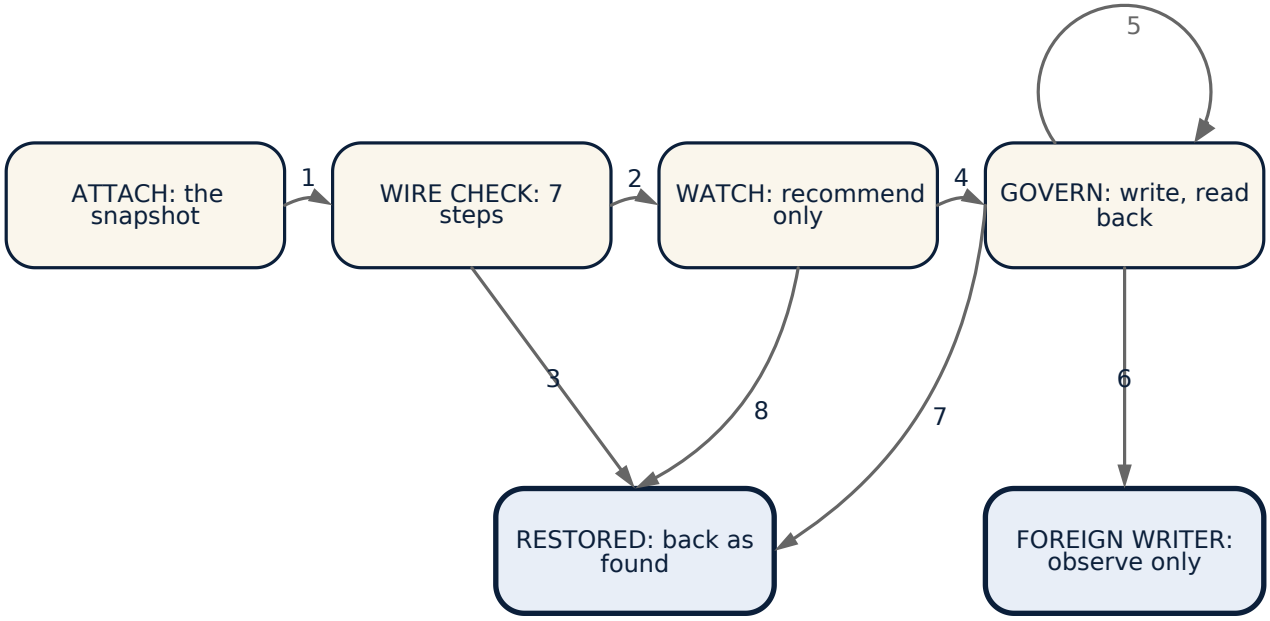
Any failure prints the wire, the step and what the device said, and nothing else runs. That turns a wiring fault from guesswork into one named line to fix.

42.5 Wired right or wired wrong

The wire check proves the wires move. It does not prove the governor reads the right thing. A correct installation leaves signatures in its own receipts; a wrong one leaves others. Check them on your first paired runs, before you believe any number, good or bad.



Check	Wired right	Wired wrong, and what to look at
Watch arm against native	equal on every gauge (watch writes nothing)	different: the probe, the load or the machine differs between arms, not Omni

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Check	Wired right	Wired wrong, and what to look at
Requests served, failed requests	equal to native	fewer served or more failed: a lever is cutting capacity; check its cover and its sign
p95 and p99 response time	at native or faster	slower: the reading or the floors are wrong (rows below)
GPU: the card's clock while busy	at or above the clock the card reaches on its own	below it: the speed floor is missing or the lid is under the card's own draw
GPU: the lid while busy	at or above the card's own busy draw	at the envelope floor while busy: the lid is sized from a curve, not from the card's own meter
GPU: credit per write (`GPU_REPS.md`)	compass decisions pace the slack, race decisions cover the bursts; fail-up is rare	fail-up in most decisions: being busy is being read as a breach, or the service line is set too low
Kubernetes: machines given back	through the release gate, one per decision, with no pod waiting	machines given back while pods wait, or none at all while the service is far inside its band: check the latency feed, `--slo-ms` and the release gate's reasons in the audit
Kubernetes: the reset	every HPA target, replica range, CPU limit and worker back to native, no record left	anything left: an earlier run or another controller wrote the same objects
Every lever after the run	at its snapshot	not at its snapshot: another writer, or a restore that failed (exit 3): restore by hand and investigate
The feed itself	fresh samples every few seconds	stale or empty: Omni reads it as blind and fails up; fix the feed, not the governor

The rule. If any row reads "wired wrong", the result of that run says nothing about Omni-Compass: fix the wiring, run the wire check and the watch arm again, and only then compare. The first real card run is the worked example: its receipts showed the card's busy clock under its own (736-768 MHz against 861-889), the lid at the 105 W floor under its own 135 W draw, and fail-up in 46% of decisions. Each of those is a row in this table.

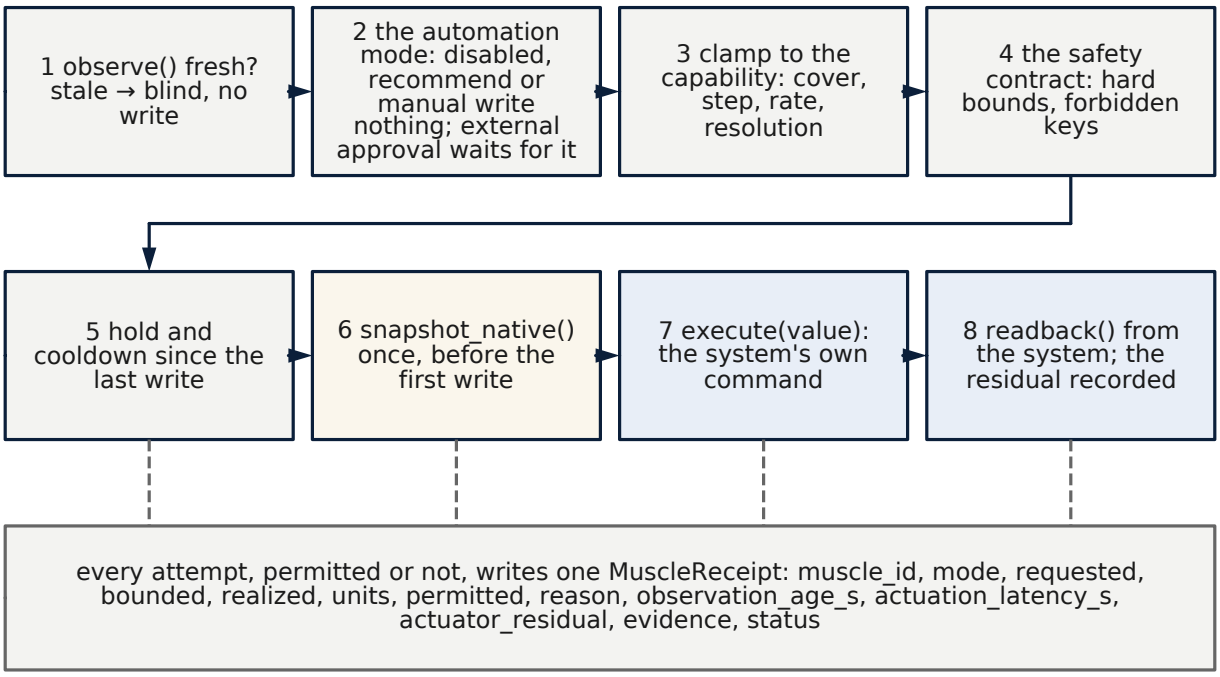
© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

1 the snapshot taken · 2 WIRED RIGHT · 3 FAIL: nothing written, the knob as found · 4 the paired trial passed · 5 every decision: clamp, gate, write, read back, receipt · 6 the knob found where the governor did not put it · 7 stop: reset, OFF, the lease · 8 stop before the trial passed

Figure 28. State machine: the life of one muscle under the plug. Attached with its snapshot, checked by the seven-step wire check, watched in recommend-only mode until the paired trial passes, then governed, one clamp, gate, write, read-back and receipt a decision; a knob found where the governor did not put it moves the muscle to observe only, and every stop restores it to the setting as found.

42.6 The wire check on the other stacks

The GPU has a one-command wire check because its wires are the hardest to get right. The other stacks carry the same proof in a different place: every Kubernetes arm records `kubectl auth can-i` receipts for what the governor's identity can and cannot do (and fails if it can do anything it must not), checks that the cluster holds nothing but the harness, and ends with the reset check that every HPA target, replica range, CPU limit and worker is back at native with no record left; every database, broker and cache arm reads the knob back after every write and hands it back at the end, and the report says "handed back: yes" or the run is invalid; every simulator arm checks that every override was handed back. The watching arm, where it is run, is the wire check of the reading: a watching governor that disagrees with native on any gauge has found a difference in the probe, the load or the machine, not in Omni-Compass.



42.7 Coding a new muscle: the muscle SDK

A muscle not in the catalog (Appendix G), or one whose native controller speaks an API no adapter covers, is coded on the muscle SDK (`omnicompass/muscle_sdk.py`, printed in full in the Source appendix), the contract every adapter obeys: **observe, bound, request, execute, read back, receipt, restore**. The SDK adds

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

a muscle and never a brain: the chain is plant telemetry → observation adapter → the same engine state → bounded authority → shield → actuator → read-back → plant, and the governing state (E, U, I[U], S, B, Ḃ) is untouched by any muscle added (Chapter 12). The governor proposes a setting; the SDK's runtime earns the authority to write it, verifies the write and writes the receipt. An engineer codes five functions and declares three contracts; everything else (the clamp, the gate, the snapshot, the restore, the receipt) is the runtime's.

The five functions (the `MuscleAdapter` protocol, or `FunctionalMuscle` for a small connector): `observe()` returns the reading with its timestamp and quality (the wire out); `snapshot_native()` records the setting as found, once, before the first write; `execute(value)` writes one setting through the system's own command or API (the wire in; **WRITES**); `readback()` reads the setting back from the system, never from memory; `restore_native(snapshot)` puts the setting back as found. The adapter owns the vendor's API; the brain never sees it.

The five functions an engineer codes: observe, snapshot_native, execute, readback, restore_native. The three contracts declared: capability, timing, safety. The runtime does the rest, in this order, for every command.

Figure 29. The muscle SDK's runtime: what happens to one command. The eight steps the runtime takes, in order, for every value the governor proposes: the observation's freshness (stale means blind, no write), the automation mode (recommend writes nothing), the clamp to the capability contract, the safety contract, the hold and the cooldown since the last write, the snapshot taken once before the first write, the execute through the system's own command, and the read-back with its residual. Every attempt, permitted or not, writes one MuscleReceipt with the fields shown.

The three contracts (`MuscleSpec`): the **capability** (`CapabilityContract`: the cover's `minimum` and `maximum`, the `resolution`, the most one write may move (`max_step`) or the most a second may move

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(`max_rate_per_s`), the `units`, whether the knob is `reversible` and whether it reads back); the **timing** (`TimingContract`: the observation and decision periods, the actuation delay, the minimum hold and the cooldown between writes, the timeout, and `stale_after_s`, past which a reading is blind); the **safety** (`SafetyContract`: the `hard_min` and `hard_max` nothing may cross, `fail_closed`, a `safe_default`, and the `forbidden` context keys, such as a security hold, under which no write is permitted). The spec also names the muscle (`muscle_id`, `plant_id`), its class (`resource_type`, one of the standard classes below), its `automation` mode and its evidence class (`Evidence`: D design, S our own models, L live software, P physical meter, C commercial).

The automation modes, from least to most authority: `disabled`; `recommend` (every command computed and receipted, nothing written: the watch level of Chapter 45); `manual`; `external_approval` (a write only with `approved=True` from your change process); `automatic`. A muscle starts at `recommend` and is promoted exactly as Chapter 45's levels promote a stack.

What the runtime does with each command (`MuscleRuntime.command`), in order: a stale or invalid observation blocks the write and marks the muscle blind (section 32.3); the mode is checked; the request is clamped to the capability (cover, step, rate, resolution); the safety contract is asked (`outside_hard_bounds`, `forbidden:<key>`); the hold and the cooldown are checked (`hold_or_cooldown`); only then is the native snapshot taken, once, and the write made, and where the capability says the knob reads back, the setting is read back and the residual (realized minus bounded) recorded. Every attempt, permitted or not, writes one receipt (`MuscleReceipt`): `muscle_id`, `mode`, `requested`, `bounded`, `realized`, `units`, `permitted`, `reason`, `observation_age_s`, `actuation_latency_s`, `actuator_residual`, `evidence`, `status`. `MuscleRegistry` holds every muscle of a body, refuses a duplicate name, answers `catalog()` (every muscle with its cover, mode, evidence and status) and `restore_all()`, which hands every muscle back in the reverse of the order they were registered.

A worked example. The power limit of one graphics card, through the card's own command, first in `recommend`:

```
import json, subprocess
from omnicompass.muscle_sdk import (
    AutomationMode, CapabilityContract, Evidence, FunctionalMuscle,
    MuscleRegistry, MuscleRuntime, MuscleSpec, Observation,
    SafetyContract, TimingContract)

def read_limit():
    # the wire out: the setting as the card reports it now
    out = subprocess.run(
        ["nvidia-smi", "-i", "0", "--query-gpu=power.limit",
         "--format=csv,noheader,nounits"],
        capture_output=True, text=True, check=True).stdout
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    return float(out.strip())

def write_limit(w):
    # the wire in: one setting, the card's own command (WRITES)
    subprocess.run(["nvidia-smi", "-i", "0", "-pl", str(int(w))],
                   check=True)

spec = MuscleSpec(
    muscle_id="gpu0.power_limit", plant_id="card-0",
    resource_type="gpu.power_limit", adapter_version="1.0",
    capability=CapabilityContract(minimum=100.0, maximum=300.0,
                                  resolution=1.0, max_step=25.0,
                                  units="W"),
    timing=TimingContract(observation_period_s=2.0,
                          decision_period_s=2.0, minimum_hold_s=10.0,
                          stale_after_s=6.0),
    safety=SafetyContract(hard_min=100.0, hard_max=300.0,
                          forbidden=("security_block",)),
    automation=AutomationMode.RECOMMEND,
    evidence=Evidence.LIVE_SOFTWARE,
    native_owner="the card's firmware")
muscle = FunctionalMuscle(
    spec, observe=lambda: Observation(read_limit()),
    execute=write_limit, readback=read_limit,
    snapshot=read_limit, restore=write_limit)
audit = open("/var/log/omni/muscles.jsonl", "a")
registry = MuscleRegistry()
registry.register(MuscleRuntime(
    muscle, audit=lambda rec: audit.write(json.dumps(rec) + "\n")))

receipt = registry.command("gpu0.power_limit", 250.0,
                           context={"security_block": False})
# recommend: permitted False, reason "recommend", nothing written;
# the receipt is in the audit
registry.restore_all()
# every muscle back as found, in reverse order; each one receipted
```

Promoted to `AutomationMode.AUTOMATIC`, the same code writes: a request of 250 W from the 300 W found is bounded to 250 and read back (residual 0); a request of 200 W ten seconds later is bounded to 225 by

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

`max_step`; a request inside the 10-second hold is refused (`hold_or_cooldown`); a request made while `security_block` is true is refused (`forbidden:security_block`) and nothing moves; `restore_all()` returns the card to the 300 W found at the start and its receipt says `restored`. These outcomes are the SDK's own tests (`tests/test_muscle_sdk.py`).

The standard classes (`STANDARD_MUSCLE_CLASSES`) name the knob a new adapter governs, so that the catalog and the receipts read the same across a company's stacks: `kubernetes.replicas`, `.cpu_request`, `.cpu_limit`, `.memory_request`, `.memory_limit`, `.hpa_target`, `.pod_placement`, `.node_pool`; `host.cpufreq`, `.cpu_quota`, `.cpuset`, `.memory`, `.io`; `gpu.power_limit`, `.clock_envelope`, `.mig`, `.admission`; `cloud.instance_count`, `.instance_size`, `.placement`, `.start_stop`, `.capacity_policy`; `storage.volume_size`, `.tier`, `.iops`, `.throughput`, `.placement`; `network.traffic_weight`, `.rate_limit`, `.bandwidth`, `.routing`; `application.concurrency`, `.worker_count`, `.queue_admission`, `.jvm_heap`, `.thread_pool`, `.batch`; `facility.cooling_setpoint`, `.rack_power`, `.site_power`. A class is a contract, not a claim that a connector for it has run live: each adapter earns its own evidence class, and Appendix G's wiring recipes say which have (`docs/wiring_recipes.csv`).

A muscle coded on the SDK is wired into a body as any other (Chapter 34): one governor per body, the muscle's reading a gauge of that body, its receipts in the body's audit; the wire check of section 42.4 applies to it unchanged (snapshot, write, read-back, restore, nothing left behind), and it enters service through the levels of Chapter 45, watched first.

CHAPTER 43

The Harness

> **Before you wire anything:** read `DISCLOSURES.md`. Omni-Compass acts only through the wires it is given; it cannot be slapped on. If your paired receipts differ from the published benchmarks in direction, the first presumption is wiring: check the installation with section 42.5 of the manual (*Wired right or wired wrong*).

This tree is the GitHub-ready kit: frozen engine + C++ twin + two plants + live stub.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

43.1 What to run

```
pip install -r requirements.txt
python verify.py --quick          # engine, C++ twins and their parity
    ↪ , soak
python k8s_controlplane/test_controlplane.py
python -m k8s_controlplane.suite  # elastic / always_on / idle_power
python tests/test_hpa_three_way.py

python tests/test_omni_controller.py
```

The machine's own power (the Linux frequency governor as native, Omni on the frequency ceiling, energy from the processor's meter; root on a machine on the metal, not a virtual one; `docs/CPU_POWER_PREREGISTRATION.md`):

```
sudo python3 tools/run_cpu_power.py --probe            # can this mach
    ↪ ine run it?
sudo bash scripts/cpu_power_run.sh                     # the three wor
    ↪ kloads, native and omni, three repetitions; one folder
python3 tools/cpu_power_abc.py A B C --out V3_CPU_POWER.md   # three r
    ↪ uns into the table
```

Fleet plant (Omni as node authority vs HPA+CA / Karpenter-lite):

```
python -m fleet.planetlab --dir fleet/traces/planetlab --scenarios 8 -
    ↪ -out /tmp/pl
```

C++:

```
cmake -S cpp -B cpp/build -DCMAKE_BUILD_TYPE=Release && cmake --build
    ↪ cpp/build -j2
./cpp/build/oc_smoke
python tests/test_cpp_compass_law_parity.py cpp/build/oc_compass_law
    ↪  # the compass law, Python against C++
python tests/test_cpp_verdict_parity.py cpp/build/oc_verdict

    ↪   # the verdict, Python against C++
python tests/test_cpp_engine_runs_parity.py cpp/build/oc_engine_runs 5
    ↪ 00   # the Python's 500 runs through the C++ harness
python tools/engine_runs.py --runs 500 --base 7 --cpp cpp/build/oc_eng
    ↪ ine_runs   # a new set, both engines, one record
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

43.2 Two plants (do not mix the tables)

Tree	What Omni is	What the energy number means
`k8s_controlplane/`	On top of HPA+CA (target / gate / park)	Pack and optional CA gate on a 20-node replica
`fleet/`	Node-pool authority; CA off	Consolidation vs CA and Karpenter-lite

Observe must match the native arm on that plant. If it does not, the run is invalid.

43.3 Engine species

Shipped `omnicompass/core.py` is the patent principal form: cubic $U(1 - U^2)$, FIG. 4 command, RK4 with held u. `omnicompass/pools.py` is actuation only (off / hold / park). It does not change the field.

43.4 The C++ twin

`cpp/` is the engine written a second time, line for line where a twin exists: the six-state core, the governor's allocation laws, the shield, the pod autoscaler's replica law, the closure, the conveyance law, the nerves, the compass and ledger, the GPU governor's rules, the compass law with the two-way plug, and the verdict. Each twin has a parity test that feeds the Python and the C++ the same inputs (`verify.py` runs them all; `tools/seal.py` lists them and what still runs in Python only). The Python's seeded runs (`tools/engine_runs.py`, 500 from the jump generator) run whole through the C++ harness too (`cpp/tools/engine_runs.cpp`: the Python's draws are its input, and the governor, the nerves, the compass law and the verdict in C++ put the mechanism on), every receipt and the SHA-256 digest identical to the Python's; the `engine-runs` workflow runs both with every set. The live engine's page, in the page's section 7b, feeds the Python's own runs into the C++ at every rebuild (`docs/engine/export_cpp_twins.py`), and its proof monitor sets the C++ engine's digest beside the Python's and the page's.

43.5 Not in this harness

Live kube-controller-manager, GPU MIG scheduler, facility cooling plant (kind runs on GitHub: `docs/K8S_COMPASS_PREREGISTRATION.md`). `omni_controller/` is observe-first against kubectl; tests use `tests/standin_cluster/kubectl`.

See `LIMITS.md`.

All patents, copyrights and trademarks filed in the USA.

CHAPTER 44

The Wiring Guide

Before you wire anything: read `DISCLOSURES.md`. Omni-Compass acts only through the wires it is given; it cannot be slapped on. If your paired receipts differ from the published benchmarks in direction, the first presumption is wiring: check the installation with section 42.5 of the manual (*Wired right or wired wrong*).

The current manual is `docs/INTEGRATION_MANUAL.md` (every stack, every level, every switch). This page is kept for reference; where the two differ, the integration manual is current.

Which knobs to wire in at all: `docs/WIRING_VERDICTS.md` gives every knob in every published result one of three words from the tables themselves: **write** (wire both ways), **watch** (wire out only: Omni reads, the native controller lives by itself) or **operator's choice** (a trade). A knob that showed nothing, or lost, stays native. **How to wire for superiority:** every knob starts in watch (wire out only); an observation run shows what native does alone; then the brain's own verdict decides on the knob, in real time, whether a notch pays before it is written (`tools/knob_verdict.py` around the engine's verdict; the manual, section 45.4); a knob that cannot prove it pays stays native, and the operator's setting is always free. Where that verdict stands today, knob by knob, is the last table of `docs/WIRING_VERDICTS.md`.

The full step-by-step manual, with the switch, the living band, parking and the pod reflex, is `docs/OPERATOR_MANUAL.md`. This page is the short version.

Three stages. Each stage adds only the permissions it needs. A stage is promoted only after its evidence is in, and the reset works at every stage:

```
kubectl -n omni-compass exec deploy/omni-compass -- touch /tmp/omni.ki
    ↪ ll
```

The switch is one human-operated switch for the whole harness (OFF restores every HPA target, replica range, CPU limit and cordon Omni-Compass changed, and records it; removing the file turns Omni-Compass back ON). It never fires by itself and never switches off one module: a failed decision is skipped, boundaries are held by the living band.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

44.1 Build the image

```
docker build -f deploy/Dockerfile -t <registry>/omni-compass:<tag> .
docker push <registry>/omni-compass:<tag>
```

What the image contains.

- The engine.
- The nervous system.
- The live controller and its levers.
- The frozen closure-law setting (`/app/law/closure.json`).

How it runs. As a non-root user, with a read-only root filesystem and no Linux capabilities.

44.2 Shadow: read-only, decides and logs, never writes

```
kubectl apply -f deploy/install/omni-compass.yaml      # set the image
    ↪  line first
kubectl -n omni-compass logs deploy/omni-compass -f
```

Proof of read-only. `scripts/pilot_shadow.sh` runs the same stage from a workstation with `kubectl auth can-i` receipts that the identity cannot write, and writes `SHADOW_REPORT.md`.

Run length. One to two weeks.

Pass condition. Zero writes, and recommendations you agree with.

44.3 Target: Omni-Compass sets each HPA's CPU target

```
kubectl apply -f deploy/rbac-target.yaml               # adds: patch h
    ↪ orizontalpodautoscalers
kubectl -n omni-compass patch deploy omni-compass --type=json -p \
  '[{"op":"replace","path":"/spec/template/spec/containers/0/args/1","
    ↪ value":"target"}]'
```

What happens. The HPAs keep scaling pods. Omni-Compass only moves their target within bounds.

The SLO reflex. Add `--latency-file` and `--slo-ms`, and the target is never tighter than native while the SLO is breached.

Pass condition. Latency never behind native, and fewer pod-hours.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

44.4 Node pool: Omni-Compass sizes the node pool

Add permissions. `patch nodes`, `create pods/eviction` (`deploy/kind/rbac-omni.yaml` is the tested example).

Set the mode. `--mode nodepool --node-scale-cmd "<your pool resize command with {n}>"`. Examples of the resize command:

- a Karpenter NodePool limit;
- a cloud node-group size;
- `scripts/kind_nodepool.sh` on kind.

What guards a release. The machine organ gives a node back only when all of these hold:

- every sense is live;
- its last order landed;
- pods are not scaling up;
- nothing is pending;
- the remaining nodes stay at or below the engine's target utilisation.

A PodDisruptionBudget on each service is required, because drains go through the eviction API.

Optional levers. Each has its own flag and permissions, and all are listed in `omni_controller/muscles.py`:

- right-sizing;
- cold start;
- batch pacing;
- agent containment;
- cooling;
- CPU frequency.

44.5 Evidence, and where it is

Evidence	File
The controller, every lever and the Unified Control Switch on real Kubernetes (kind)	`results/live/LIVE_LEVERS_2_NERVOUS.txt`
Read-only shadow on real Kubernetes: every decision logged, 0 writes	`results/live/LIVE_SHADOW_1.txt`
Least-privilege identity receipts	`rbac_omni.txt` in every live run

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Evidence	File
Native vs Omni on top vs Omni alone, paired on one machine, real Kubernetes	`results/live/LIVE_PAIRED.md`
The full wiring manual	`docs/OPERATOR_MANUAL.md`
The frozen engine's results, three runs each, read by rule	`results/live/V1_*.md`, `results/live/V3_*.md`; `docs/OMNI_V1.md`, `docs/OMNI_V3.md`
The same wiring on Azure's managed Kubernetes (the bill), a database pooler, a rented machine, the simulators, a message broker's consumer group, a cache's memory ceiling, a drone swarm's autopilot	the manual, chapter 32 (`docs/OMNI_COMPASS_MANUAL.md`)

CHAPTER 45

Before You Start, and the Eight Levels

45.1 What your system needs

You run	You need
Kubernetes (vanilla, EKS, GKE, AKS, OpenShift/OKD, Rancher, kind)	Kubernetes 1.34 or newer (in-place pod resize); metrics-server (`kubectl top nodes` works); an HPA with a CPU target on each governed service; a readiness probe and a short preStop pause on each service
A response-time feed (strongly recommended at every level)	a CSV per service, `elapsed_seconds,latency_ms,ok`, written continuously; `scripts/latency_probe.py` writes one against any HTTP endpoint
NVIDIA GPUs	a driver with `nvidia-smi`; root (or the capability to run `nvidia-smi -pl` and `-lgc`); on a VM, full GPU passthrough
CPU power control	Linux cpufreq with the schedutil governor; RAPL for package watts; usually bare metal

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

You run	You need
Site power and cooling	a command that prints site watts, and a command that sets the supply-air setpoint through your building management system

Why each requirement is there. Kubernetes 1.34 or newer is required because the conveyance muscle resizes a pod's CPU limit in place, which older versions do only by restarting the pod, and a restart is a disruption Omni-Compass never causes. metrics-server is the HPA's own eyes and the governor's: without it neither knows what the pods use. An HPA with a CPU target on each governed service is the native controller Omni-Compass sits on; a service without one has nothing for level 2 to move. A readiness probe and a short preStop pause are what make a drain invisible to clients: the Service stops sending requests to a pod before it stops, and kube-proxy sends them to another ready endpoint. The response-time feed is the one wire a cluster does not already have: Kubernetes knows what its pods use, not what its users wait; the compass needs the second, and `scripts/latency_probe.py` writes it against any HTTP endpoint every five seconds. On the GPU, root is needed only for the two `nvidia-smi` writes, and a VM must pass the whole card through or the driver refuses to lock clocks (the wire check's step 3 is where that shows).

45.2 Get the software and check it

```
git clone https://github.com/The-Omni-Compass-LLC/The-Omni-Compass-LLC
    ↪ .git
cd The-Omni-Compass-LLC
pip install -r requirements.txt
python3 verify.py                        # every check; ends with VERIF
    ↪ ICATION: PASS
```

Build the container image once:

```
docker build -f deploy/Dockerfile -t <your-registry>/omni-compass:<tag
    ↪ > .
docker push <your-registry>/omni-compass:<tag>
```

It runs as non-root, with a read-only root filesystem and no Linux capabilities.

What `verify.py` checks is worth knowing before it is run, because its last line, `VERIFICATION: PASS` or `FAIL`, is the only thing a reader has to read. It runs every test in `tests/` (the law, the plugs, the readings rule, every benchmark's own harness against a stand-in server), checks the engine's fingerprints against the preregistered registry so that a changed engine file fails before anything is measured, compares the release's files with its manifest (`tools/release_manifest.py --check`: the engine, the C++ twins, the live evidence's digests, one object that names the commit it was written at) and runs the layout check (`tools/layout_check.py`: the declared root, every link and every named path present). It takes a few

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

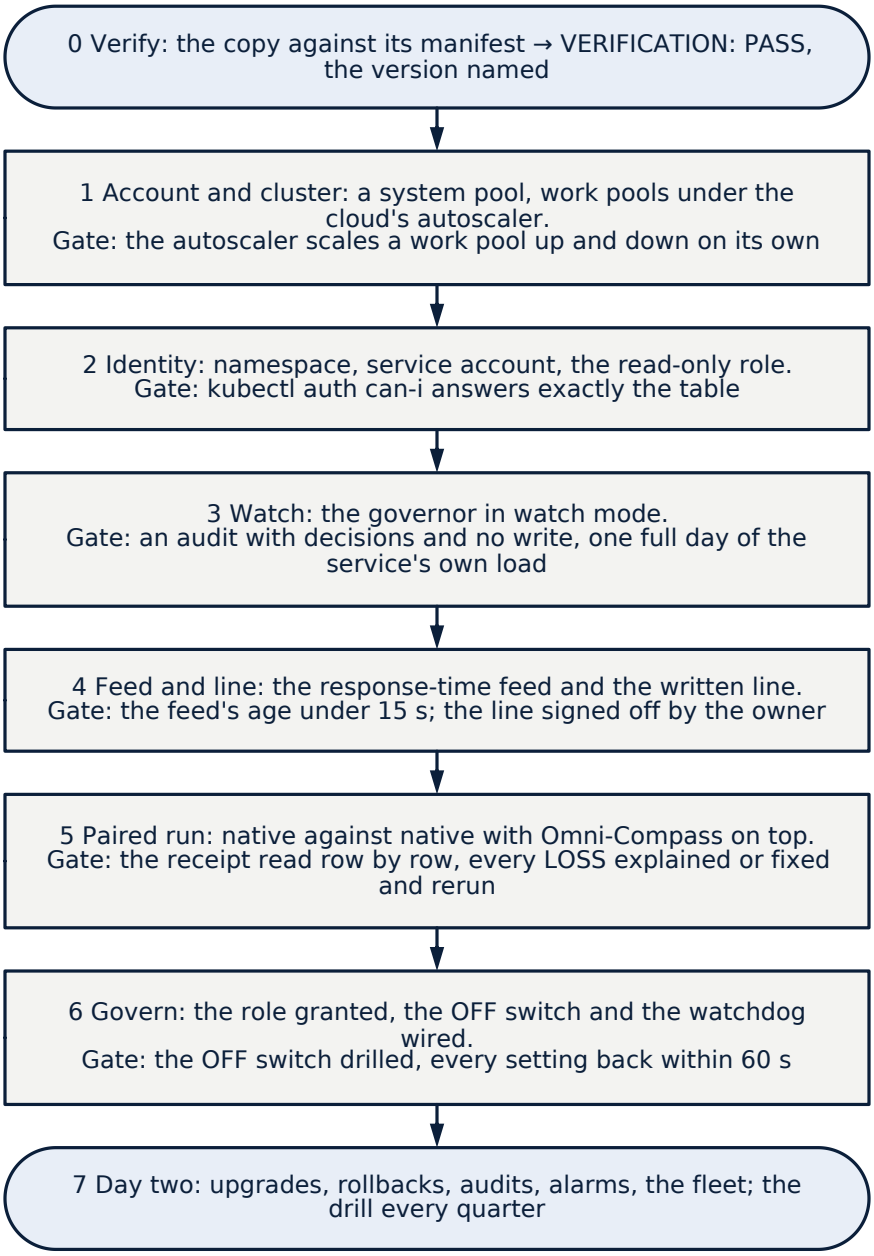

Figure 30. Flowchart: the implementer's eight phases and their gates. From the verified copy through the account and the cluster, identity, the watch, the feed and the line, the paired run and the governing grant to day two; each phase has a gate that must pass before the next begins, and the OFF switch is drilled before the governor writes.

minutes on a laptop and needs no network beyond the clone. GitHub runs the same script on every push under Python 3.12, and each run is listed under the repository's Actions tab with the commit it checked; a result in this manual is only ever cited from a commit whose run passed.

To know which engine a checkout carries, ask it:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
python3 tools/omni_version.py                  # omni-v11, omni-v10, o
    ↪ mni-v9, omni-v8, omni-v7, omni-v6, omni-v5, omni-v3, omni-v2, om
    ↪ ni-v1, or what differs
python3 tools/omni_version.py --commit <sha>   # the same question of
    ↪ any pushed commit
```

Every result table in `results/live/` cites the commit it ran on, and the three-run tools refuse to combine runs from different engines (Chapter 59). The founder's standing order is that no result is ever read across engines, and the command above is how a reader checks that for themselves.

45.3 The levels

Take them in order. Each has a pass condition; go to the next level only when it holds. The OFF switch works at every level.

The levels exist because a governor earns authority the way a new operator does: by watching first, then by touching the setting that is cheapest to undo, then the next. Level 0 touches nothing and proves the software is the software (`verify.py` checks every sealed file's fingerprint and runs every test). Level 1 watches a live cluster for as long as the operator likes and logs every decision it would have taken, so the operators can read those decisions against what they would have done; nothing passes level 1 until they agree with its readings. Level 2 moves the HPA target, which the HPA itself corrects within a minute if the governor is wrong, and raises replica floors ahead of bursts; it is the first level that can show a gain and the first that can show a loss, and the paired receipts of Chapter 57 are its pass condition. Level 3 moves machines, the slowest lever, through the release gate and the verdict; it is where the bill moves and where the most care is spent. Level 4 hands Omni-Compass the replica decision itself, with the HPA kept as the fast reflex upward; it is an option, not a step on the way, and the benchmarks in this manual do not use it. Levels 5 to 7 are the GPU, the CPU and the site, each with its own wire check and its own pass. An installation may stop at any level and run there indefinitely; most will stop at level 3.

Level 0 - Evaluate without touching anything.

```
python3 verify.py
python3 tools/run_scale.py --runs 10 --scale 1 --out results/scale/eva
    ↪ l     # the seven organisms, modelled
python3 tools/run_gpu_card.py results/sim/gpu_two_wire/eval
    ↪        # the two-wire card, modelled
```

Pass: `VERIFICATION: PASS`. Nothing in your systems is touched.

Level 1 - Watch (read-only).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

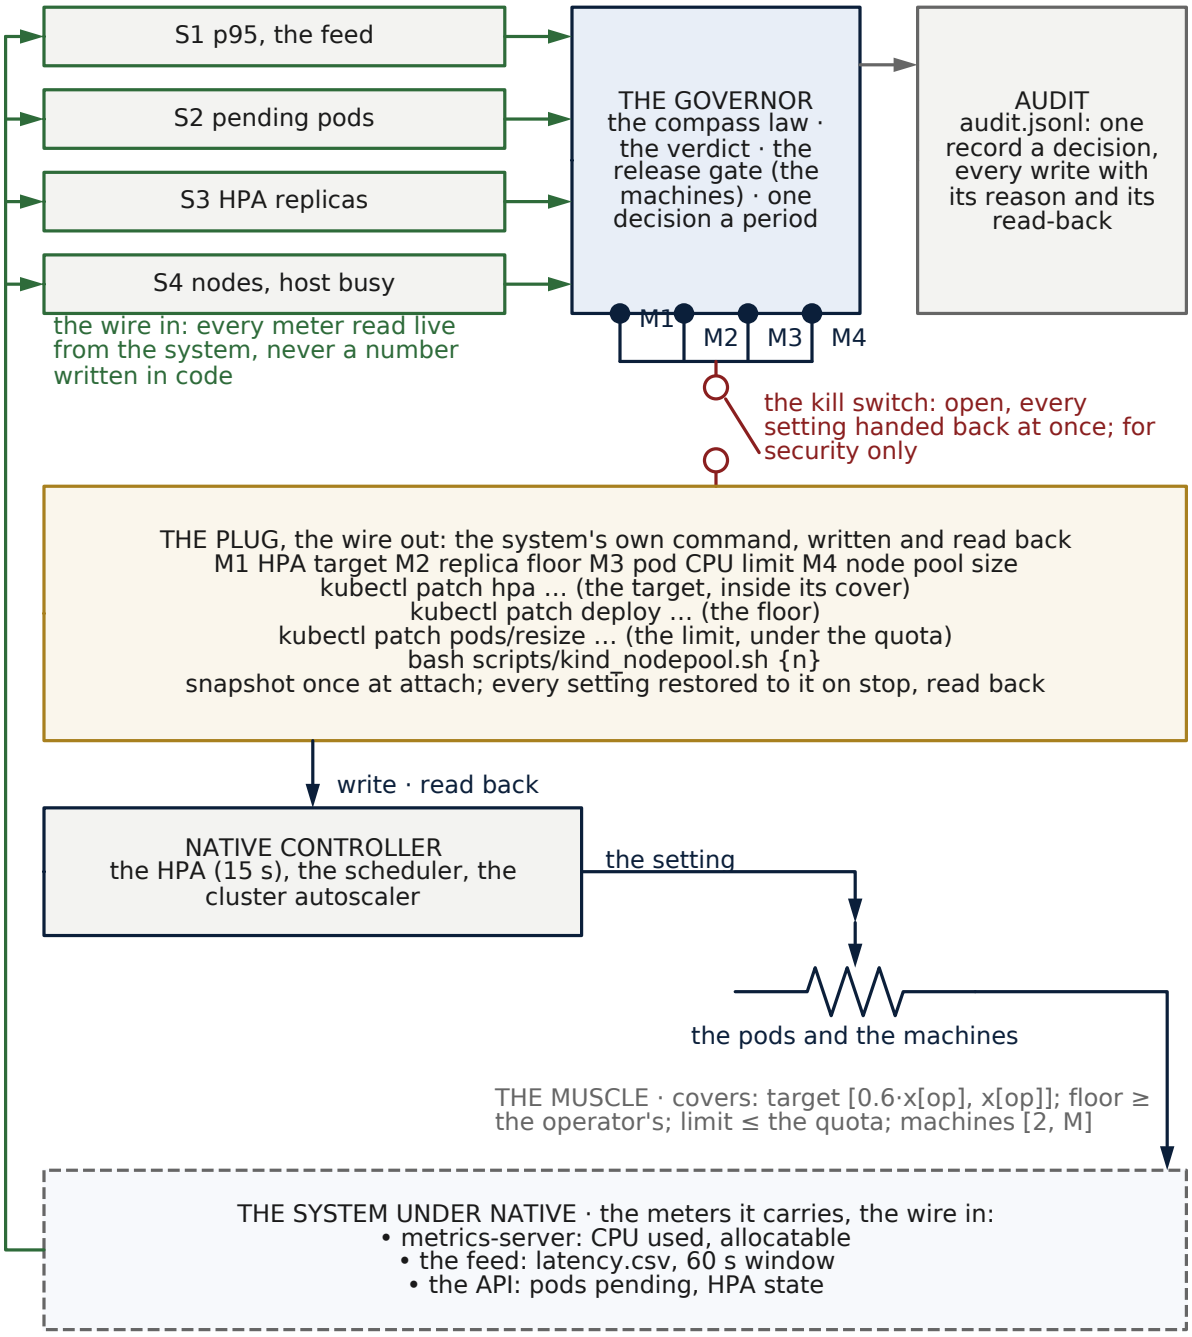

Figure 31. Wiring schematic: Kubernetes in the cluster, levels 2 to 4. The schematic is read top to bottom as an electrical drawing: the governor (the control unit) with its sense terminals S1, S2, … on the left and its motor terminals M1, M2, … on its lower edge; the motor bus through the kill switch into the plug, the system's own command written and read back; the plug into the native controller; the native controller setting the muscle, drawn as a potentiometer with its cover; the system under native carrying the meters; and the meters back along one bus, the wire in, to the sense terminals.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The audit stands beside the governor. Here the senses are the response-time feed, the pods waiting for a place, each autoscaler's replicas, and the machines with the host's busy share; the motors are the autoscaler's target, the replica floor, the pod CPU limit and the node pool size, each through kubectl's own patch and resize commands. Level 2: the target and the floor; level 3: the machines through the release gate and the verdict; level 4 (--strict-replicas): the replica decision itself. The HPA keeps its own 15-second check underneath. Nothing is ever deleted or evicted; a parked machine is emptied by the autoscaler's own scale-down.

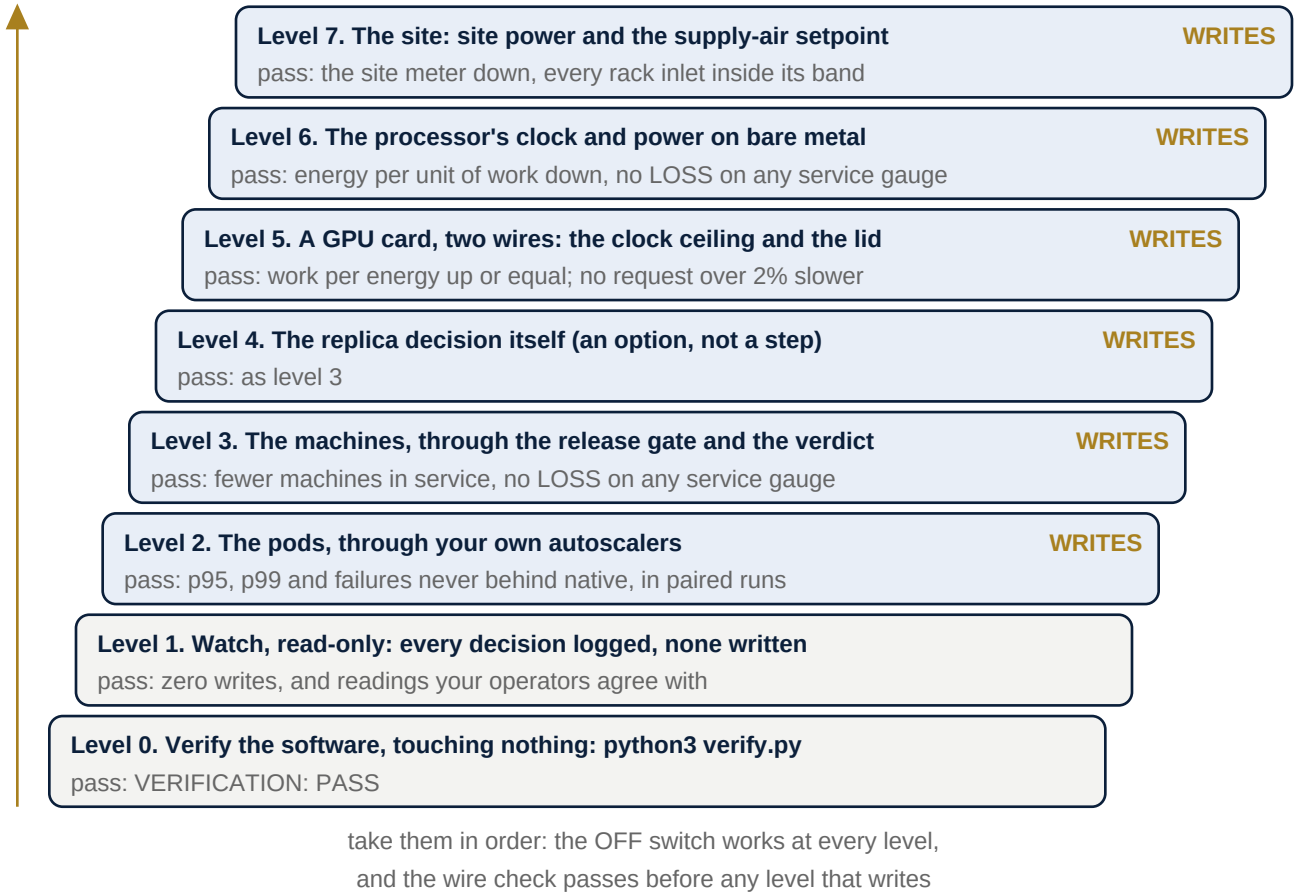

Figure 32. The eight levels of an installation, taken in order, each with its pass condition. Levels 0 and 1 write nothing; from level 2 the governor writes, and the wire check must pass before any level that writes. An installation may stop at any level and run there indefinitely.

```
kubectl apply -f deploy/install/omni-compass.yaml     # set the image
    ↪ line; it runs --mode observe
kubectl -n omni-compass logs deploy/omni-compass -f
```

The install file grants a read-only identity; `scripts/pilot_shadow.sh` records `kubectl auth can-i` receipts that show it cannot write. Every decision it would take is logged with its reason. Pass: zero writes, and readings your operators agree with.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Level 2 - The pods, on top of your autoscalers. WRITES.

1. Grant `patch horizontalpodautoscalers` and `patch pods/resize` (`deploy/rbac-target.yaml`).
2. Run with `--mode target --latency-file <feed> --slo-ms <your p95 target>`.
3. Optional pod muscles, one at a time:

Muscle	Switch	What it does
convey	`--latency-file` and `--cap-deployments ns/name`	gives each machine's idle CPU to the serving pods on it
rightsize	`--rightsize-deployments ns/name`	each pod's CPU request follows its measured use times (1 + headroom), in place
coldstart	`--coldstart-deployments ns/name` `--coldstart-signal ns/configmap`	scales a service to zero while no work waits, wakes it when work arrives
batch	`--batch`	admits held Jobs labelled `omnicompass.io/batch=true` when there is load and power headroom
batch pace	`--batch-pace`	pauses Jobs labelled `omnicompass.io/pausable=true` under power or heat stress, resumes them after
rollout guard	`--rollout-guard ns/name`	pauses a rollout while change is not permitted
contain	`--contain-namespaces ns` `--contain-cpu-m <m>`	holds an agent namespace to a CPU budget
security hold	`--security-configmap ns/name`	key `hold: "true"` blocks every expansion

Your HPAs keep scaling as before; Omni-Compass sets their targets and raises floors ahead of bursts. Pass: p95, p99 and failed requests never behind native, over paired runs (Chapter 57).

Level 3 - The machines. WRITES.

1. Grant `patch nodes` and `patch pods` (`deploy/kind/rbac-omni.yaml`).
2. Run with `--mode nodepool --active-nodes-only --closure /app/law/closure.json --node-scale-cmd "<command with {n}>"` and `--node-restore-cmd "<command>"` for the OFF switch. For the compass law on the same levers, use `--law compass` (reads the mean response time of the latency window between a tenth of `--slo-ms` and `--slo-ms`, held at `--compass-center 0.4`; p95 at the SLO, a blind feed or a

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

waiting pod adds capacity at once; the HPA target never goes above the operator's; machines go back one at a time through the release gate).

Your platform	The park/wake command
any cluster, bare metal, kind	`bash scripts/kind_nodepool.sh {n}`
Karpenter / EKS Auto Mode	the NodePool CPU limit at `{n}` times node CPU, parked nodes kept
Cluster Autoscaler node group	the group's desired size, scale-down through parking
OpenShift / OKD	the worker MachineSet replicas, parked

A machine is given back only when every sense is live, the last order landed, pods are not scaling up, nothing waits for a place, and the remaining machines stay inside the band. Pass: fewer machines in service, with no LOSS on any service gauge.

Level 4 - Omni-Compass decides; Kubernetes is the muscle. WRITES. Add `--strict-replicas`: Omni-Compass decides each service's replica floor and when to shrink; the HPA stays as the fast reflex upward. Pass: as level 3.

Level 5 - A GPU box, two wires. WRITES.

```
sudo python3 tools/gpu_wire_check.py --gpu 0                    # must
    ↪  end: WIRED RIGHT
# watch: computes both wires and writes neither
sudo python3 -m omni_controller.gpu_compass --mode watch --gpus 0 --au
    ↪ dit /var/log/omni/gpu.jsonl \
     --latency-file <feed> --slo-ms <p95 target> --floor-w <your lowes

    ↪ t watts>
# govern: writes the clock ceiling and the power limit
sudo python3 -m omni_controller.gpu_compass --mode cap --gpus 0 --audi
    ↪ t /var/log/omni/gpu.jsonl \
     --latency-file <feed> --slo-ms <p95 target> --floor-w <your lowes
    ↪ t watts>

# OFF: clocks reset, power limit back to the start, read back
sudo touch /tmp/omni-gpu-kill
```

Every `--interval` seconds (default 2) it reads the card's own meters and the response times, and:

- **learns the card on its own** first: while the ceiling is at the top and the card is busy, its busy clock and busy draw; until 15 such readings are in, neither wire moves;
- **races while work waits**: at 95% utilization or more, the ceiling to the top and the lid to the start limit;

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **paces the slack**: the mean response time of the last 5 s, between a tenth of `--slo-ms` and `--slo-ms`, held at the compass's center (0.4); the ceiling moves in whole 15 MHz steps, never under the card's own busy clock, and the lid never under the card's own busy draw plus 10%, never over the start limit;
- **asks the card first (the verdict)**: before the ceiling may go one step lower, a paired trial measures the card's own time on each request (the workload's `service_ms`) at the top and at that step; the step is allowed only if it adds at most `--allow` (2%). Where no step passes, the ceiling stays at the top: the card runs as it does alone, and the audit says so (`verdict_state: left native`);
- **fails up** when p95 reaches `--slo-ms`, a request fails, the feed goes blind or the card reports a heat slowdown.

One law, no profiles: down gain 0.0125, center 0.4, floor at the card's own busy clock, allowance 2% (GPU preregistration, amendment 8). The workload must write `service_ms` (the card's own time per request) in its latency file, as `tools/gpu_workload.py` does; without it no step is ever allowed and the card stays native. Pass: work per energy up or equal; requests served equal; no request more than 2% slower at the median, p95 and p99 at native or within 2%; every row of section 42.5 reads "wired right".

Level 6 - CPU clock and power. WRITES. On bare metal, add to the controller: `--cpufreq-policy-root /sys/devices/system/cpu/cpufreq --cpufreq-require-schedutil --rapl-cmd "<prints CPU package watts>"`. The OFF switch writes every policy's recorded maximum back exactly. Pass: energy per unit of work down, no LOSS on any service gauge.

Level 7 - Site power and cooling. WRITES. `--power-cmd "<prints site watts>" --site-limit-w <limit>` brings site power stress into the engine; `--cooling-cmd "<sets {c}>" --cooling-min-c 18 --cooling-max-c 27 --cooling-restore-c 22` lets it hold the supply-air setpoint in its band. CPU and GPU sharing one power budget (`hardware/node_exchange.py`) and GPU groups sharing a site budget (`hardware/site_exchange.py`) run as models today. Batteries are designed as an organ, not yet wired.

45.4 Wiring for superiority: watch first, then the brain's own verdict on every knob

The founder's order of 9 October 2026 fixes the order of wiring. Every knob is wired out first and in last, and the wire in is connected only by a measurement the brain makes on the knob itself. The steps, for any stack:

1. **Wire out, everything.** Every muscle's readings reach the brain, one wire out per muscle. Nothing is written. This is watch mode (section 1.3): where every installation starts, and where any knob returns the moment it stops paying.
2. **Run the observation.** With the stack together and under its real or replayed demand, let the brain watch for at least one full cycle of that demand. In watch mode the brain learns the band of every reading, where the native controllers hold them, and which readings leave calm and when. Nothing is decided yet; the audit says what the brain saw.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

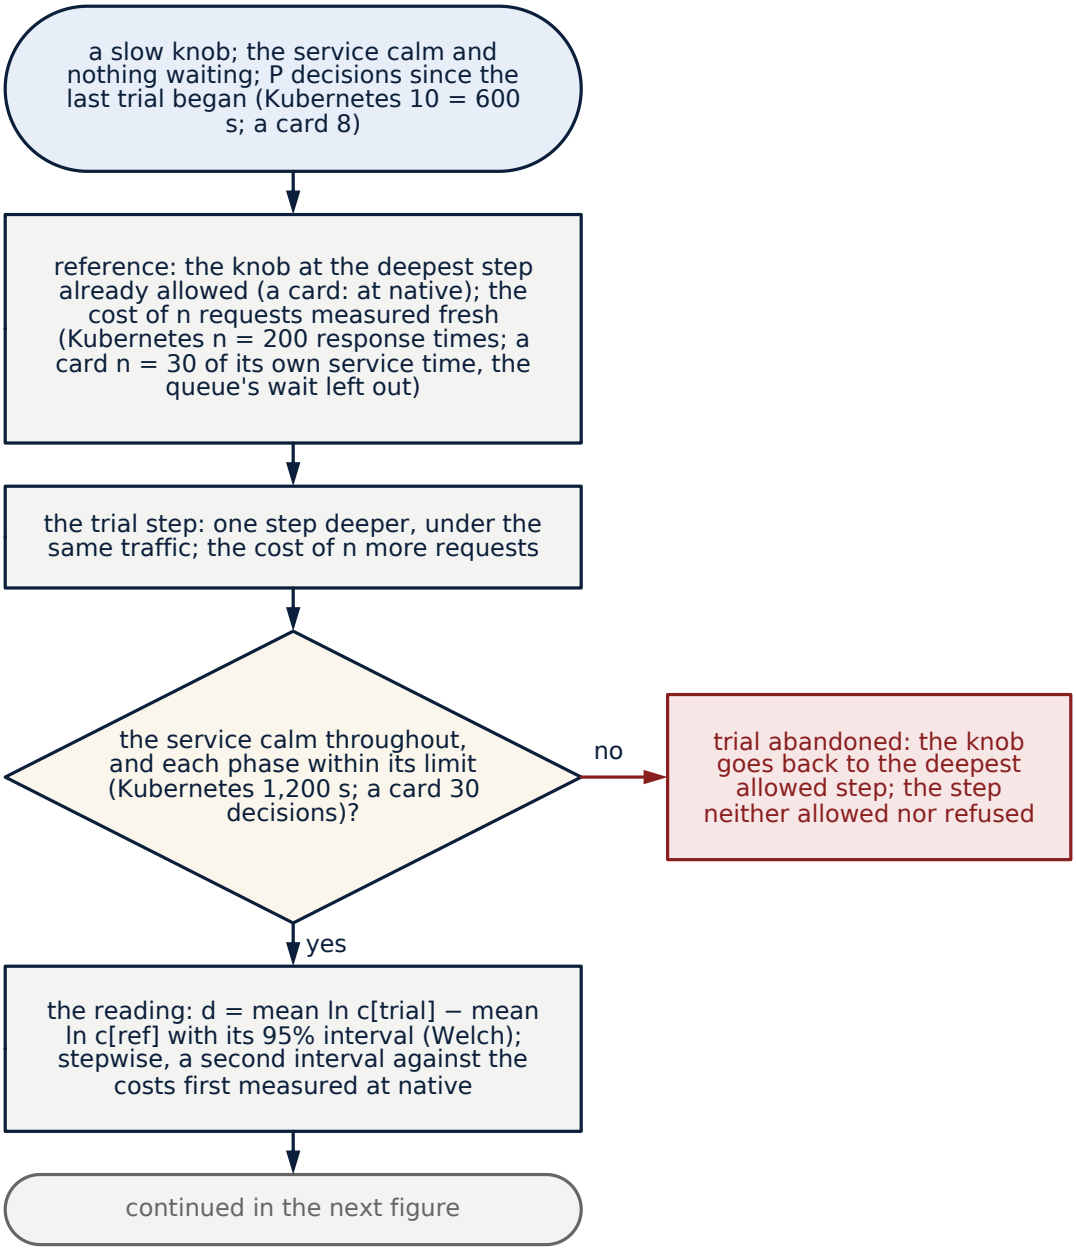

Figure 33. Flowchart: the verdict's trial on one step, from the reference to the reading. While the service is calm and nothing waits, and P after the last trial began (600 s on Kubernetes, 10 decisions at a 60 s beat, the factory's through a cloud, 60 at its 10 s on site; 8 decisions on a card), the reference is measured fresh at the deepest step already allowed (on a card, at native): n requests (200 response times on Kubernetes; 30 of a card's own service time).

One step deeper, under the same traffic, n more are the trial. A phase that sees the service leave calm or outlasts its limit (1,200 s on Kubernetes, 20 decisions at a 60 s beat, 120 at 10 s; 30 decisions on a card) is abandoned: the knob goes back, the step neither allowed nor refused. The reading is the 95% interval of the change in log cost. Continued in the next figure.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

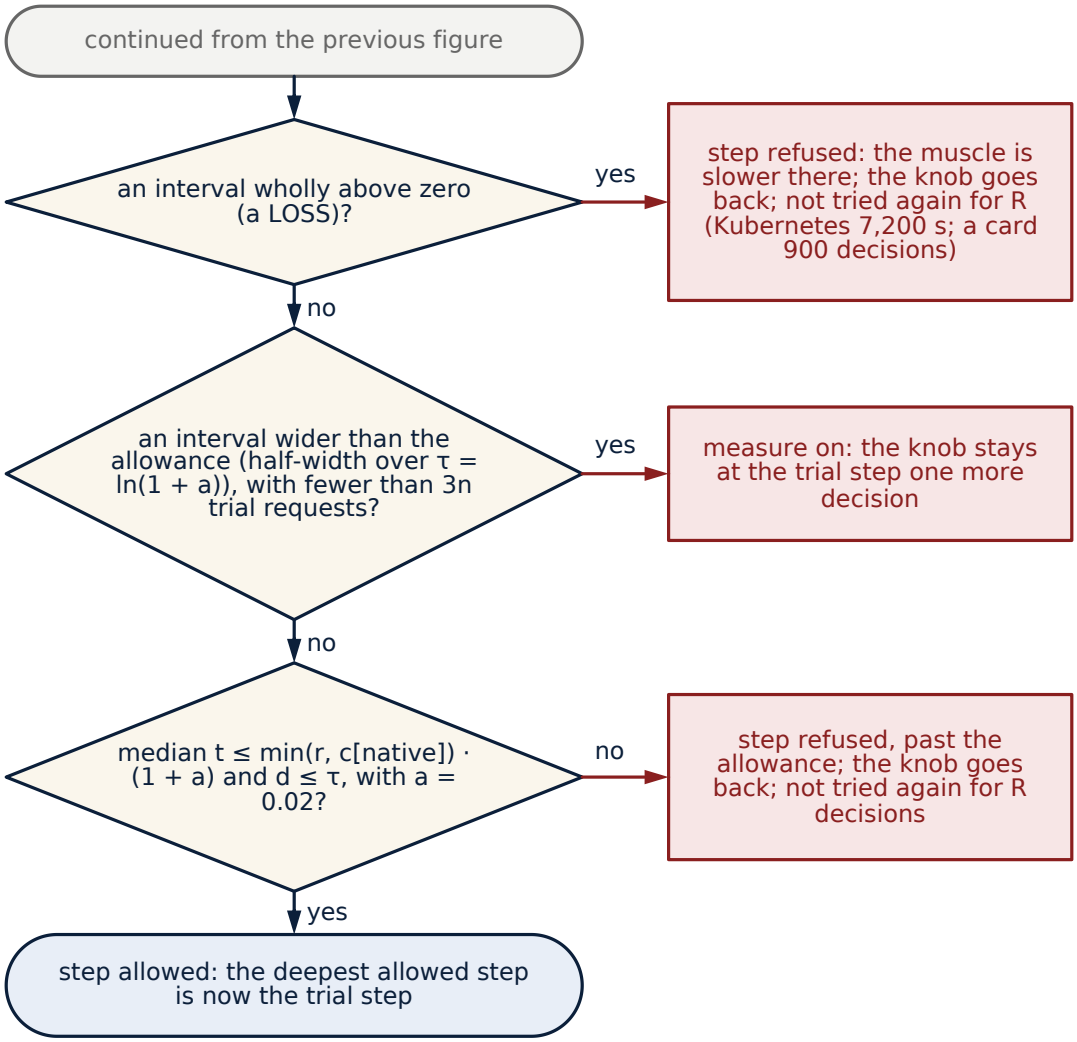

Figure 34. Flowchart: the verdict's trial on one step, from the reading to the step allowed or refused. An interval wholly above zero is a LOSS: the step is refused, the knob goes back, and the step is not tried again for R (7,200 s on Kubernetes, 120 decisions at a 60 s beat, 120 at 10 s; 900 decisions on a card). An interval wider than the allowance with fewer than 3n trial requests measures on. Otherwise the step is allowed only if the trial's median is within the allowance of the reference and of native and the mean change is within it too; else it is refused, past the allowance. An allowed step moves the deepest allowed step one deeper.

3. **Let the verdict decide each knob, one trial at a time.** Switch the knobs the operator is willing to have moved into verdict mode. A knob still writes nothing until the brain has run a paired trial on it (section 1.2; `omnicompass/verdict.py`; on the live stacks `tools/knob_verdict.py` around it): the knob is held at the operator's setting for a reference, then one notch away, under the same traffic, and the step is allowed only if the muscle's own cost did not rise under the declared objective. The objective is the operator's one declaration per knob: the resource reading (the service, the resource and the CPU weighed together, the default and the index's own reading) or the service reading (work and speed alone). A

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

refused step is not retried for a set time; an allowed step widens the allowance by one notch, and the next trial probes the next. The compass then moves the knob by its law inside the allowance, never outside.

4. **Keep checking.** The trials recur. A knob whose last step stops paying when the demand changes is refused on its recheck and the allowance narrows back; a knob that never passes a trial stays native for good, which is the right answer for that knob and costs nothing. New noise in the system is answered the same way: the compass reacts inside the allowance within its time constant, and the allowance itself is re-earned by measurement.
5. **Read the verdicts, muscle by muscle.** The audit carries the state of every knob every second (`verdict_phase`, `verdict_direction`, `allowed_low`, `allowed_high`, the cost sample) and the arm's record sums it; the wiring page (`docs/WIRING_VERDICTS.md`, section 16.6b) is the same judgement made from the published tables after the fact. An operator who wants one knob wired both ways and another watched only sets the objective on the first and leaves the second in watch.

What this gives: no knob is ever written on faith. Where Omni-Compass can beat the native controller on the muscle's own gauges, it will have proved it on that muscle before it moved it; where it cannot, the muscle lives by itself and Omni reads it. The organism's superiority is then the sum of the knobs that earned it, not one turn of a single dial for the whole system. On the five live stacks of Chapter 46 this is built and declared (the amendments of 9 October in the Redis, Kafka, PostgreSQL, MySQL and YCSB preregistrations); the counted runs on it were dispatched on 10 October, three runs a stack and objective, the expectation written before them (`docs/RERUN_2026-10-10.md`). On the Kubernetes controller the verdict already guards the machines (section 1.2). Inside the modelled realms the organism still takes one directive for every muscle; making the verdict per muscle there is the next engine, Omni v4 (`docs/OMNI_V4_PLAN.md`), designed and not built, because every result must be run again on a new engine.

CHAPTER 46

Stack by Stack

Every wiring below is the same plug (Chapter 42): one wire in (the stack's own meter), one wire out (one setting the stack already accepts), a snapshot taken once before the first write, every write read back, everything restored on OFF. Native is always the stack's own controller left as shipped; omni is that controller with Omni-Compass on top.

Stack	Levels	Notes
Vanilla Kubernetes, kind, Rancher	1-7	as written

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

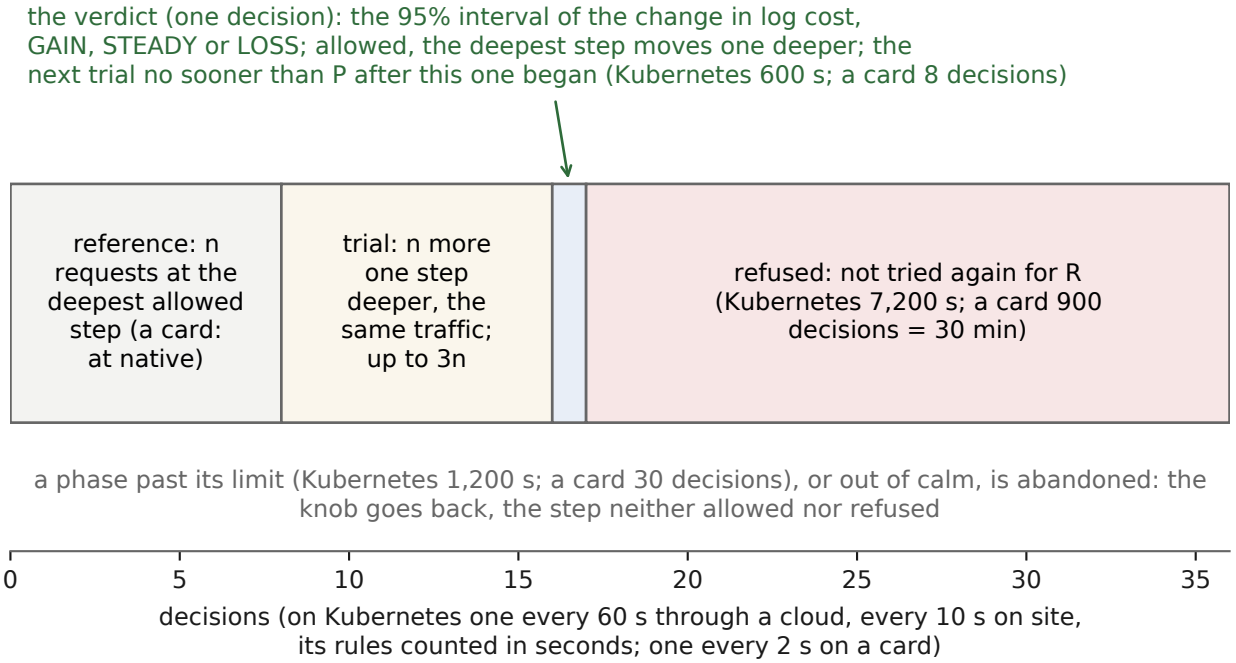

Figure 35. Timing diagram: a give-back trial from reference to verdict, in decisions. The reference (n requests at the deepest allowed step; on a card, at native), the trial (n more at one step deeper under the same traffic, measuring on up to 3n while the interval is wider than the allowance), the verdict in one decision, and, on a refusal, the quiet period in which the step is not tried again (7,200 s on Kubernetes, 120 decisions at a 60 s beat, 120 at 10 s; 900 decisions on a card, 30 min).

A phase that outlasts its limit (1,200 s on Kubernetes; 30 decisions on a card), or sees the service leave calm, is abandoned: the knob goes back, the step neither allowed nor refused.

Stack	Levels	Notes
Amazon EKS	1-5	machines via Cluster Autoscaler node group or Karpenter; CPU power control is not exposed on EC2 VMs; GPUs on bare-metal or full-GPU instances
Google GKE, Azure AKS	1-5	the provider's node-pool size as the park/wake command; on AKS the managed cluster autoscaler stays native and deletes the machines Omni-Compass idles (10.1)
Red Hat OpenShift / OKD	1-5	the same permissions through a Role; machines via the worker MachineSet

All patents, copyrights and trademarks filed in the USA.

Stack	Levels	Notes
NVIDIA GPU servers without Kubernetes	5	the two-wire GPU governor alone
Bare-metal CPU servers	6	cpufreq and RAPL through sysfs
Slurm / HPC	5 on the GPU nodes	a job-level Slurm connector is not built
Building management	7	through your BMS's command line or API, in the command templates
PostgreSQL behind PgBouncer (any database behind a pooler with a console)	one knob	the pool size through the pooler's own admin console (10.2)
A power grid's substation tap changer (pandapower, SimBench)	one knob	the tap position, one whole tap per move (10.3)
Buildings with batteries (CityLearn)	one knob a building	the battery's charge and discharge inside the simulator's own limits (10.3)
Robot arms (MuJoCo Menagerie)	one knob an axis	the joint speed where the axis has slack; never on an axis at its takt (10.3)
A rented cloud machine running the big organisms	the whole harness	the detached run: rent, run, collect, delete (10.4)
A message broker's consumer group (Apache Kafka)	one knob	the consumer count inside [1, partitions], read from the consumers' own records; the rebalance paid on every move (10.5)
A cache's memory ceiling (Redis)	one knob	`maxmemory` through the cache's own console, grown only while the cache is full (10.6)
Drone swarms (gym-pybullet-drones; PX4 and ArduPilot next)	one knob a drone	the cruise override inside the autopilot's limits; a separation wall; collisions void the cell (10.7)
A database's storage-engine cache (MongoDB under YCSB)	one knob	the WiredTiger cache size through the server's own console, grown only while the cache is full (10.8)

46.1 Managed Kubernetes on Azure: the bill as the gauge

On Azure Kubernetes Service the muscle is the same as on kind (Chapter 45, levels 1 to 3) and one thing is new: the bill is real. The workflow `aks-metered` builds a fresh cluster for every arm the same way: a system pool of one machine, tainted so no workload lands on it (Azure's add-ons and the load generator live

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

there; it is never measured and never governed), and one or several **work pools** under Azure's own cluster autoscaler, every pool labelled `omni-role=work`, every pool starting full. Native is that autoscaler alone. Omni on top is the same autoscaler with Omni-Compass idling the machines it gives back, which the autoscaler then deletes on its own schedule. The bill counts every work machine that exists, every 15 seconds, priced at Azure's list price for its family (`tools/live_reps.py`, `POOL_PRICES`); each cluster is deleted when its arm ends, so nothing keeps billing.

Sizing the fleet to the lever. The smallest saving a fleet can show is one machine. On 4 workers one machine is 25% of the fleet, so only a saving of about 30% or more can clear the noise; on 15 workers about 10%; on 96 about 3%. The expected machine saving under Omni-Compass is a few percent, so the 4-worker runs (`results/live/V1_AKS_STEADY.md`, `V1_AKS_BURST.md`) cleared the noise on no gauge, which is the honest reading of a fleet too small for the lever, not a result against it. A new subscription allows 200 vCPUs in a region but 10 per machine family, so one family gives five 2-vCPU workers; the way past it is **several families at once**: eight pools of four to five workers each make a fleet of 39 (`worker_pools` input, `size:max,size:max,...`; `pool_prices` names each family's price). The app's replica ceiling is raised with the fleet (`hpa_max`: nine 200-millicore pods fit one 2-vCPU worker, so 9 × workers lets the fleet fill), the same in both arms. The preregistered design is in `docs/K8S_COMPASS_PREREGISTRATION.md`, "The fleet that can show one machine"; the account setup, click by click, in `docs/AZURE_SETUP.md`.

In the cloud, the work the bill buys. In a public cloud every machine that exists is billed, whether it carries work or not. The cloud runs the whole engine at the max, as on site (`dial max`, the `dial` input of `aks-metered` and its default; the founder's order of 31 October struck the tune-down on the machines alone of 14 October): the governor moves the service's pod target inside its autoscaler's cover, conveys the processor a machine can spare, and parks a machine the cloud already made only after its own trial shows the response time holds, waking it on a breach; the cloud's own autoscaler, native's machine controller, stays in every arm and alone adds machines. The set must show that the engine holds: no judged gauge LOSS against native, the work per dollar read beside the bill; the benefit is made at the software end and at the chip and comes through the wire. A smaller bill is never the aim; a company that wants a cut turns the dial down (`dial save`, a changed tune, its receipts its own). The bill is shown beside the work it bought, never ruled. In the cloud, as everywhere, the governor's fast checks (the scheduling floor, the pod reflex, and the conveyance every 15 seconds whichever check falls due) run every 5 seconds, three times as fast as the HPA's own 15-second check, and its full decision every 60 seconds, the factory beat through a cloud (omni-v24, which decides every 10 seconds on site; omni-v17 to omni-v23 decided every 60 seconds everywhere, omni-v16 every 15 seconds, the HPA's own pace, and every engine before it every 60 seconds), the beat a dial from 5 to 120 seconds. Through v6 a shorter decision period was not a free setting: the give-back trial's phase (`max_trial`, 20 decisions), the breach cool-down (`--slo-clear`), cruise (`--cruise-after`) and the trial spacing counted in decisions, so at 5 seconds a trial would have lasted 100 seconds, too short for the 200 response times it measures, and no machine would ever have been given back (`docs/K8S_COMPASS_PREREGISTRATION.md`, "The decision period in the cloud"). v7 states every one of them in seconds (`--slo-clear-s 180`, `--cruise-after-s 120`, `--strict-window-s 300`,

All patents, copyrights and trademarks filed in the USA.

The audit stands beside the governor. The senses are the probe's feed, the pods waiting and the machines in service; the only motors park a machine (a PreferNoSchedule taint), wake it (the taint removed) and mark its pods first to go; no autoscaler is moved, no processor conveyed, no power capped. A machine is parked only after its own trial (the response time holds within 2%) and woken on a breach: at the next decision (15 s) for a response time over the line, at the next fast check (5 s) for a waiting pod. No cloud credential: the governor holds a Kubernetes service account that can read, taint and annotate, nothing more.

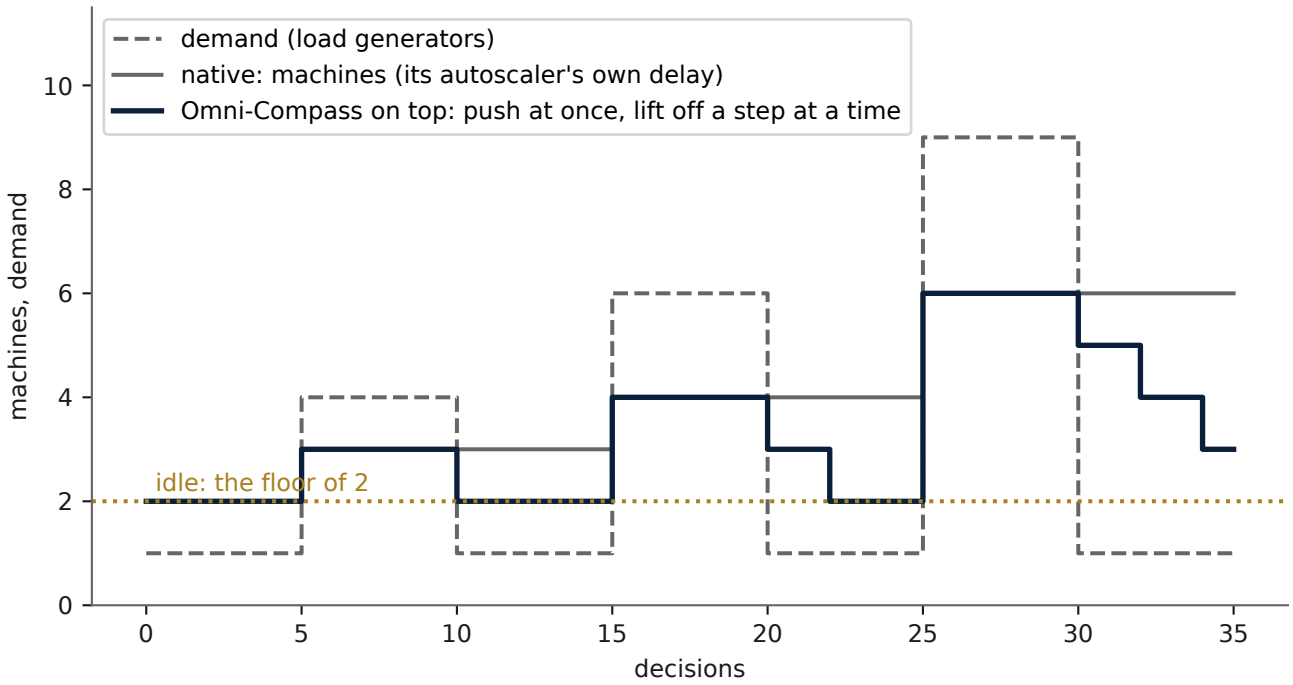

Figure 37. Modelled trace: one pedal over a burst, machines against demand (class S: the rules of the pedal drawn over the burst 1 4 1 6 1 9, five decisions a step). Native's autoscaler adds a machine when pods cannot be placed and removes one after its own delay; with Omni-Compass on top the push adds capacity at once at the wall and the lift off gives it back one machine at a time through the gate and the trial, never below the floor of 2.

`--verdict-every-s 600`, `--verdict-recheck-s 7200`, `--verdict-trial-s 1200`) and converts each to decisions at the running period, n = max(1, round(seconds / period)), so at 60 seconds every count is v6's (the cruise wait never under two readings, omni-v17: at 90 and 120 seconds its 120 had rounded to one decision, and a single reading with a pod waiting put every machine in service; `docs/OMNI_V17.md`, section 3); the compass's step on the HPA target and its coasting are scaled by period / 60, so the target moves the same amount a minute, and a pool gives back at most one machine a minute at any period (`docs/OMNI_V7.md`, section 4). The default period stayed 60 seconds, because the governor core still advanced its own state one fixed step per decision, and other counts were still written in decisions. omni-v16 (`docs/OMNI_V16.md`) puts every one of them in seconds: the brain's blending of each reading, 1 − (1 − 0.339)^k a step with k = period / 60 s, so 0.339 a minute at any period; its inner time, k of its macro interval a step; its dwell and waits; the machines it adds or removes, up_max and down_max over the last

All patents, copyrights and trademarks filed in the USA.

minute's steps (the C++ twin identically); the compass's damping, critical at the minute, and its smoothing, 0.3 a minute; the edge's window, narrowing, forgetting and wobble, per minute; the additions past the scheduling floor, one step a minute; a command's minute to land; the host's busy share over a minute; the heat law's 0.86 a minute; one batch job a minute; the conveyance every 15 s whichever check falls due; and a loop that keeps its own schedule, skipping a missed slot. At 60 s every value is the one before, so the model gate reads omni-v15's decisions exactly (4,578 audit records, none different); the period changes only how often the governor looks. With that, the founder first set the heartbeat, the full decision, at 15 s (omni-v16, the morning of 22 October: "15 sec all over heart beat"), and the same afternoon, having read the reads of the cluster each pace buys (about 86,400 a day at 5 s against 39,700 at 60 s), made it a dial with the main engine at 60 s (omni-v17, `docs/OMNI_V17.md`): the default `--interval` is 60 s and `--floor-interval` 5 s in the governor, every rig and every install file; any beat may be set (5, 15, 30, 60, 75, 90, 120 s and every value between), each shown beside native with what it buys and what it costs (`results/model_gate/V17_LADDER.md`; on the live engine page, the page's section 1j, `#s-dial`), and three runs read every beat against native and against 60 s (`docs/PACE_PREREGISTRATION.md`, amendment 3). The cushion each muscle keeps is set in seconds by its own climb, wobble and reaction time, so it is the same at any pace; a longer period would not widen it, only leave the governor blind for longer between looks. In the cloud v7 also made the whole rule one flag, `--give-back-only`, enforced in the governor itself: every actuator but the node pool off, the replica ceiling 0, the dial at the tune-down (`docs/OMNI_V7.md`, section 5); the founder's order of 31 October struck that rule, and nothing passes the flag since.

What the Azure runs taught us. Three lessons, each recorded as an amendment to the preregistration before the fleet was dispatched again. First, a fleet is sized by the lever, not by the budget: a 4-worker fleet cannot show the few-percent machine saving the law makes, so its honest reading is "inside the noise", and running it again would not change that. Second, a new subscription's allowance is per machine family, so the fleet that can show one machine is built from nine families at once, each pool at its own list price, and the bill prices each pool separately. Third, a cloud region can refuse a new cluster for hours at a time (Azure's capacity for new control planes in its region, on both control-plane tiers); the harness therefore checks the subscription's allowances before it builds anything, so a refusal costs cents and not a cluster, and every refusal is recorded with its time.

46.2 A database behind its connection pooler

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

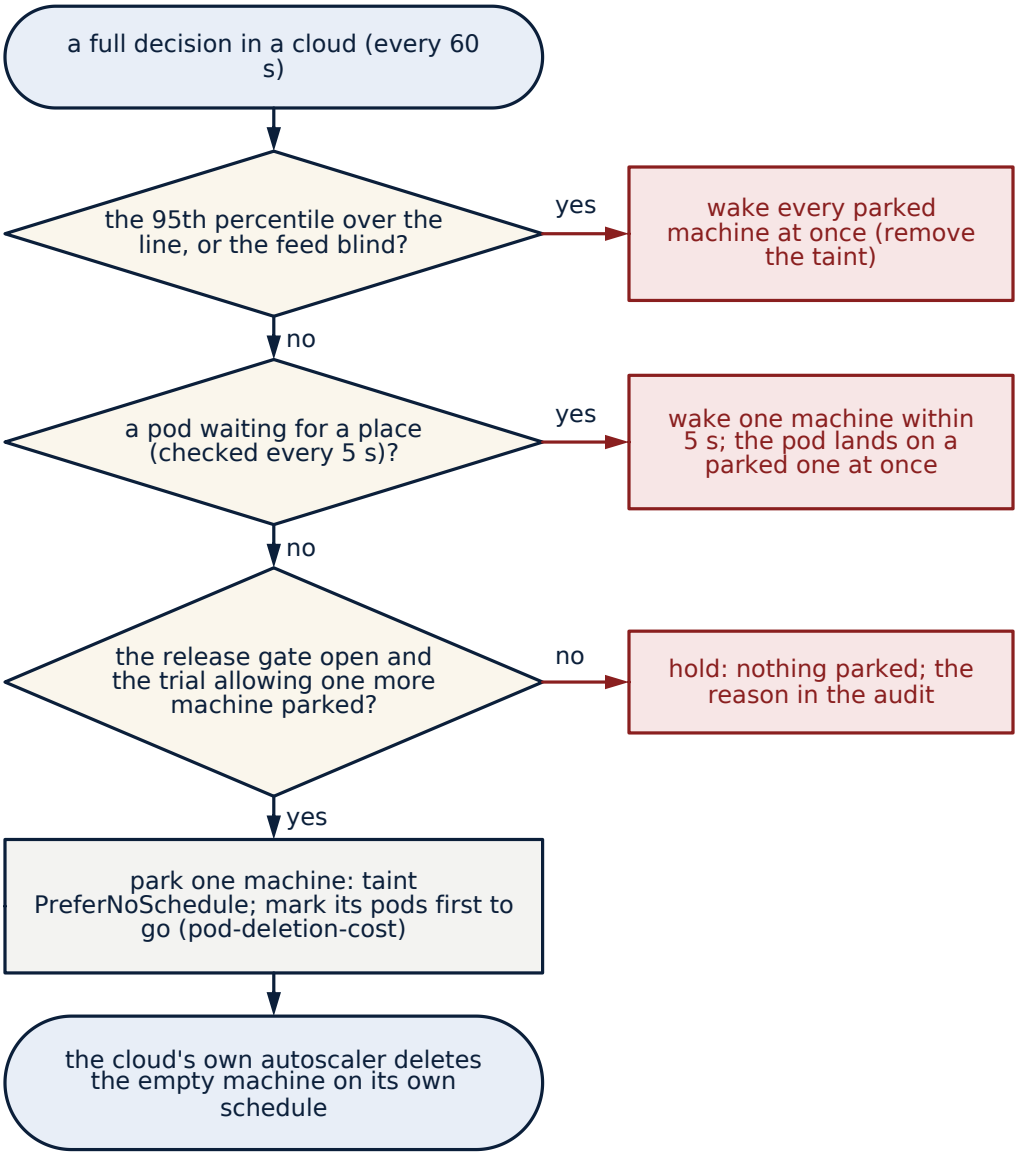

Figure 38. Flowchart: parking and waking a machine in the cloud. At every full decision: a 95th percentile over the line, or a blind feed, wakes every parked machine at once; a pod waiting for a place, checked every 5 s, wakes one machine within 5 s while the pod lands on a parked one at once; otherwise, only with the release gate open and the trial allowing it, one machine is parked (a PreferNoSchedule taint, its pods marked first to go), and the cloud's own autoscaler deletes it once empty, on its own schedule.

PostgreSQL is wired through PgBouncer, the pooler most of its deployments already run (`docs/POSTGRES_PREREGISTRATION.md`, `tools/run_pgbench.py`). Nothing models the database. The wire in is the pooler's own report (`SHOW STATS`, `SHOW POOLS`): once a second, the time a transaction spent in the server plus the time clients waited for one, over the transactions completed. The wire out is one setting through the pooler's own admin console, `SET default_pool_size`, inside the cover [2, 90]: never under two server connections, never within ten of PostgreSQL's connection limit. The compass

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

holds that reading at 40% of a 50 ms line. Where the time was spent decides the direction: waiting for a server grows the pool; time inside the server shrinks it by one, so fewer backends fight for the same cores; calm gives back one idle server a second, and only one the pooler itself shows idle. At 95% of the line the knob is handed back to the pooler's own setting at once. If the knob is found at a value Omni-Compass did not write, it stops writing (one writer). At the end of every omni arm the pool size is restored to the snapshot and read back. The same plug fits any pooler or proxy with a console and a pool-size setting (PgBouncer, Pgpool-II, ProxySQL, the application's own pool).

What the database taught us. The first untouched run on this stack was a loss, and it stays in the preregistration as it came (`docs/POSTGRES_PREREGISTRATION.md`, "The first untouched run, and amendment 1"): on the read-only workload the pooler's own clock read 0.11 ms a transaction against a 50 ms line, so the law gave back one idle connection a second until the pool stood at its floor of two, while the users' 95th percentile went from 4 ms to 3.9 s. The pooler could not see the time a client spent behind its own schedule waiting to send, so its clock said calm while the users waited; the preregistration had said so in one line without drawing the consequence. Amendment 1, declared before any counted run, made the reading the larger of two: the pooler's service time, or the share of its clients queued for a server, so a pool too small for the offered rate shows at the pooler as clients waiting and the knob fails up to the operator's setting at once; and it held the dwell when lifting off only, never when pushing. The counted runs are three new untouched runs on the amended rule; the first run is not counted and is not hidden. The result the same in all three of our runs is a resource held, not speed, and its cost the same in all three of our runs is the host's CPU: the compass's own reads of the pooler's console every second are CPU the native pooler never spends, and they are counted against it.

What the cost turned out to be (amendment 2, 8 October). The record had explained the +14% to +28% of host CPU as "PgBouncer queuing clients behind a smaller pool", without a measurement. Measured, it was ours. The pooler's own log of one counted workload holds 7,956 logins to its admin console, one for every `psql` process the harness launched to take a reading (about two a second in both arms for the sampler, four more a second plus three per write in the omni arm for the brain); one launch costs about 52 ms of CPU on a machine of the runner's class, because psql loads libpq, OpenSSL, GSSAPI and LDAP and connects before it runs one command; and a paired repetition of `select` with a per-process meter put +55.9 CPU-seconds on those launches against a +52.8 s difference in the host total, with PgBouncer at +1.2 s and PostgreSQL at −4.7 s. The second cost in the table, the median latency +15% to +17%, was the take-back rule giving back one idle server a second whenever the pooler's service time read calm, which against a 50 ms line it always did, so the pool was shrunk into a queue the pooler itself was reporting. Amendment 2, declared before the second counted set (`docs/POSTGRES_PREREGISTRATION.md`): the harness speaks the pooler's wire protocol over one connection held for the whole arm, in both arms, so no process is launched for a reading; the queue line: a server is taken back only while the pooler's clients waited for one under one percent of its time in the last second and a transaction was served, and while they waited one percent or more servers are added back, one for every percent of waiting, up to the pooler's own setting (the one-percent line the two other database tests already use), so the pool probes down to the smallest size that serves without waiting and gets its servers back the moment anyone waits; and the harness records its own CPU beside the host's. The engine's 40 files

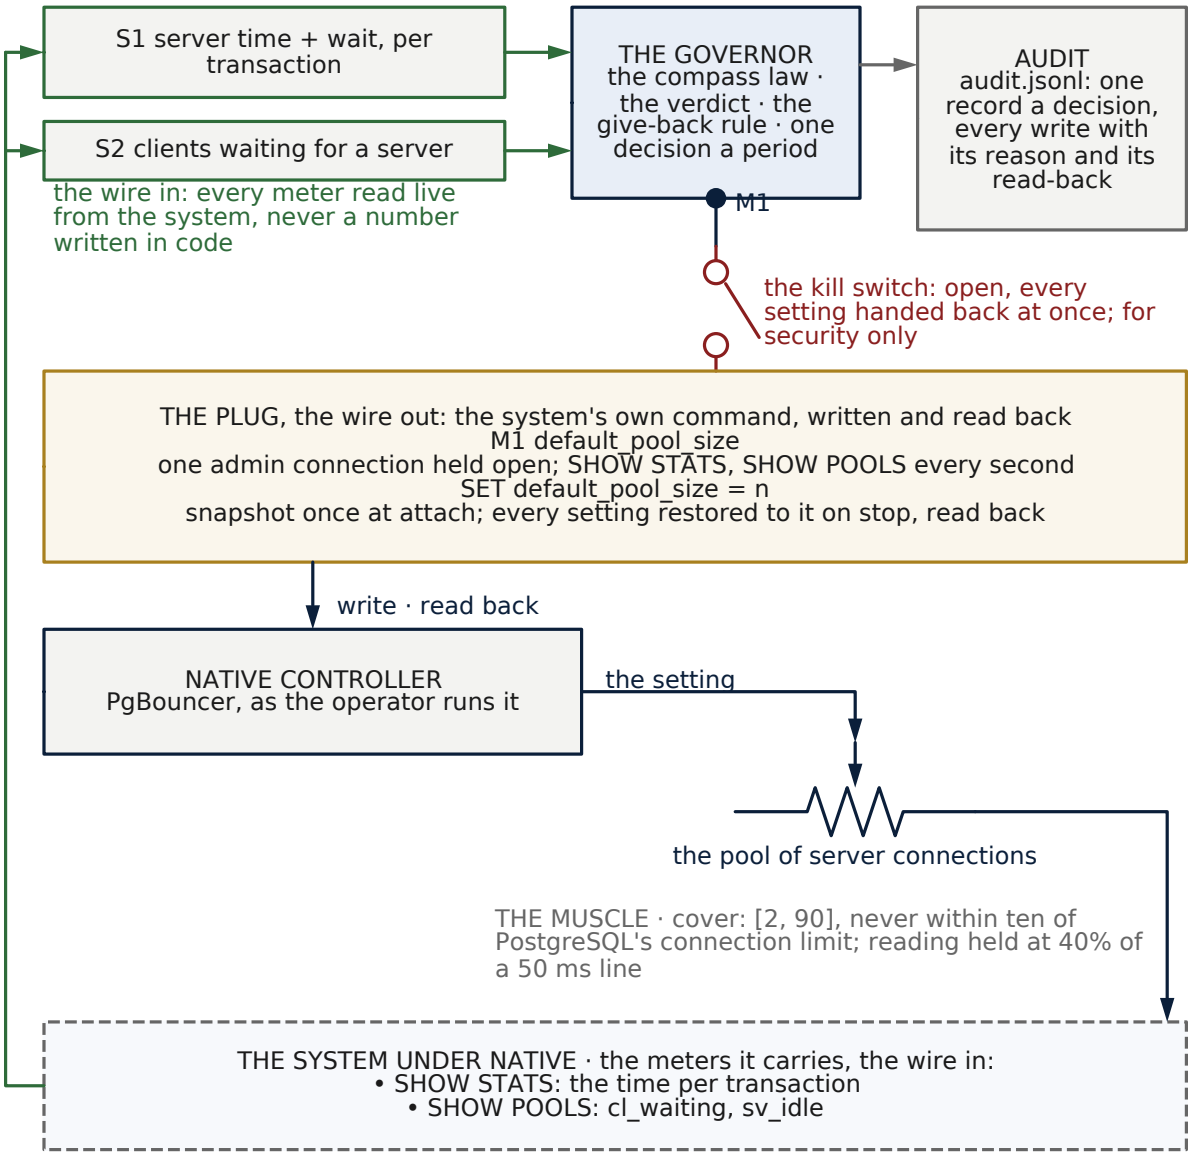

Figure 39. Wiring schematic: a database behind its connection pooler. The schematic is read top to bottom as an electrical drawing: the governor (the control unit) with its sense terminals S1, S2, … on the left and its motor terminals M1, M2, … on its lower edge; the motor bus through the kill switch into the plug, the system's own command written and read back; the plug into the native controller; the native controller setting the muscle, drawn as a potentiometer with its cover; the system under native carrying the meters; and the meters back along one bus, the wire in, to the sense terminals.

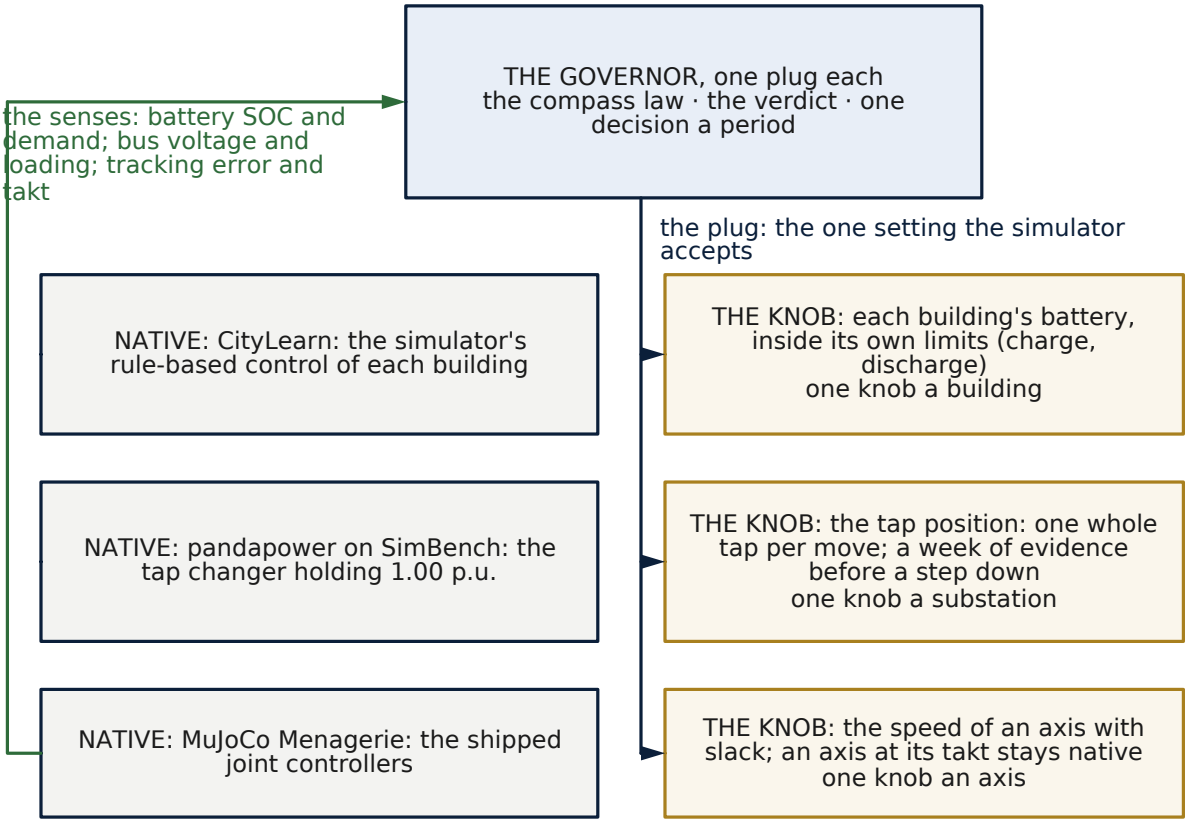

The audit stands beside the governor. The senses are the server time plus the wait per transaction and the clients waiting for a server; the one motor is default_pool_size, written over one admin connection held open. Up: a server for every percent of clients waiting; down: one idle server, only while clients waited under 1%; at 95% of the line the pool goes back to the pooler's own setting at once. One writer; the restore read back at the end.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

are untouched (`tools/omni_version.py` prints omni-v3). The second set's table replaces the first when it lands, and the first moves whole to `docs/history`.

46.3 Independent simulators, each with its own native controller

Three published simulators are wired the same way, and the simulator's own controller is always native:

The simulator's own controller is native in every cell; the plug writes the one setting it accepts, reads it back and restores it at the end. Receipts are class S: statements about the simulator's model, never about hardware.

Figure 40. Wiring schematic: three independent simulators, each on its own native controller. One plug for each: CityLearn's rule-based control of each building, pandapower's tap changer on SimBench, and the shipped joint controllers of the MuJoCo Menagerie. The governor writes the one setting each simulator accepts, reads it back and restores it at the end; the senses come back along one bus. Receipts here are class S: statements about the simulator's model, never about hardware.

- **CityLearn** (`tools/run_citylearn.py`): every district the simulator ships; the knob is each building's battery charge and discharge inside the simulator's own limits; the native arm is the simulator's own rule-based control.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **pandapower on SimBench grids** (`tools/run_pandapower.py`): the knob is the substation tap changer, one whole tap per move and a week of evidence before stepping down; the native arm holds the tap at 1.00 per unit as the grid ships.
- **MuJoCo Menagerie robot arms** (`tools/run_mujoco.py`): the knob is the joint speed of an axis that has slack; the paired physics trial written before the run leaves an axis at its takt native, so UR5e and iiwa 14 have nothing for Omni-Compass to move and the Gen3 and Panda do.

Each is preregistered (`docs/CITYLEARN_PREREGISTRATION.md`, `docs/PANDAPOWER_PREREGISTRATION.md`, `docs/ROBOTICS_PREREGISTRATION.md`), each runs A, B and C as separate GitHub runs, and each table is made by rule (`tools/citylearn_abc.py`, `tools/pandapower_abc.py`, `tools/mujoco_abc.py`). These are evidence class S: statements about the simulator's model, never about hardware.

What the simulators taught us. Three things a referee should weigh. First, a deterministic simulator makes the three-run rule stricter, not looser: MuJoCo and pandapower reproduce to the digit on any machine, so their A, B and C must agree to the digit and any difference is a finding about the harness, while PyBullet reproduces only to a part in a thousand across machines, which the swarm table discloses as an amendment and tolerates by that much and no more. Second, a knob that cannot pay is left alone by the physics, not by a rule of thumb: the robot arms' paired trial showed that two of four arms gain nothing from a speed override and left them native, the cooling model showed that a cap on cooling power can never remove less heat and so is never a lever, and a battery's reserve is spent only at the wall because every round trip through the cells costs the efficiency loss (`docs/MECHANISM_OF_ACTION.md`, 9.6). Third, a gain in one gauge is often a loss in another, and the simulators show both: the grid's losses rise in the four grids with their own generation while the energy drawn falls everywhere; the buildings' bills rise in the 2023 districts while their peaks fall; the Panda's copper loss rises while its torque falls. The tables carry every one of those rows, and the index carries none of them, because they are models.

46.4 The big organisms on a rented machine

The whole tower and the four stacked at 100 copies (about 110,700 and 190,800 modelled muscles) with a real cluster inside are also run on rented eight-core machines, **detached** (`.github/workflows/big-organism-detached.yml`), so that the cluster has more cores under it than GitHub's four-core runner gives: `start` rents one Azure machine, installs the tools, starts every repetition of every organism under `nohup` and leaves the machine running on its own; `collect` (every two hours on the clock, or by hand) copies the files back when every repetition has finished, publishes one artifact per cell and deletes the machine; `survey` lists which machine sizes and quotas a subscription may rent, region by region, and rents nothing. A machine older than `max_hours` is collected as it is and deleted, so nothing runs forever on the bill. The commit to run is an input, so a run is always tied to one engine. **The clock rule** (Chapter 57) and the rig's protocol (3 from 13 October, 4 from 18 October) decide the window for each size on each machine: the window is set from the heavier arm's step, timed on the machine before either arm, so the organism keeps its clock (the tower at 100 copies on 14 October: 2,880 s windows on three

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

machines, ten repetitions in all; the stack follows on the same three machines). No 1,000-copy run is started from 12 October; earlier engines' 1,000-copy runs on this workflow stand as they were run, in their own tables.

The same workflow carries a second test. With the input `test=robust` the machine runs the robustness harness's long scenario instead of an organism (`scripts/kind_paired.sh` with `ROBUST=long`, exactly as the GitHub job runs it), with the window stretched to whatever `duration_s` asks and the wandering load schedule repeated to fill it; the 24-hour run of section 60.15 uses it, one paired repetition on each of three rented eight-core machines of three families (the start job tries the size it is given and falls back through the eight-core sizes the subscription may rent when the allowance refuses it; the four-core size asked for was refused because the tower's machine held its family's allowance, and the preregistration records what was rented), collected and deleted at 60 hours at the latest. The cells it writes are named `robust-long-x<window>-<repetition>` beside the organisms' `six-<organism>-x<copies>- <repetition>`, and the collect job gathers both. The `max_hours` input is the machine's own limit, written into the machine at start, so a collect that finds a machine past its limit takes what is there and deletes it, whichever job started it.

Three things a reader should know about any detached result. The machine is one Azure virtual machine rented for this run alone, not a GitHub runner shared with a queue of other jobs, so its size is known (the table names it) and it is not cut off at six hours; that, and not only the job limit, is why the big organisms are run there. The files come back exactly as the machine wrote them, copied cell by cell with the machine's own log beside them, and the archive bot stores them under the collect run's number with a SHA-256 list of every file, so the start run and the collect run are both cited in the table. And the machine is deleted after the collect, so a result cannot be re-read from the machine, only from the archived files; the preregistration says this before the first start.

46.5 A message broker's consumer group

Apache Kafka is wired as an operator runs it (`docs/KAFKA_PREREGISTRATION.md`, `tools/run_kafka.py`): one broker as shipped, a topic of eight partitions, a consumer group at the operator's count of two. Nothing models the broker. The wire in is the group's own end-to-end latency: each message carries its production time, each consumer records when its handling ended, and the reading is the mean over the messages consumed in the last second; a second with nothing consumed while messages wait reads as the line (someone is waiting and no one is taking), and nothing consumed with nothing waiting reads as calm. The wire out is the count of consumers in the group, which is what an operator changes, inside the cover [1, 8]: never fewer than one, never more than the topic has partitions. The compass holds the reading at 40% of a 500 ms line with a response time of 3 s, because a consumer added or removed shows only after the group rebalances. Slow service with messages waiting adds consumers in proportion to the force; calm with nothing waiting gives back one idle consumer a second after a five-second dwell; at 95% of the line every consumer the topic can use starts at once. The rebalance that every move costs is paid by Omni-Compass and counted in the gauges. At the end of every omni arm the count is handed back to the operator's and read back.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The result (Chapter 60) is the shape this wiring predicts: the queue kept short, no message lost, at the cost of consumers running, which reads power given by rule and stands beside the gain.

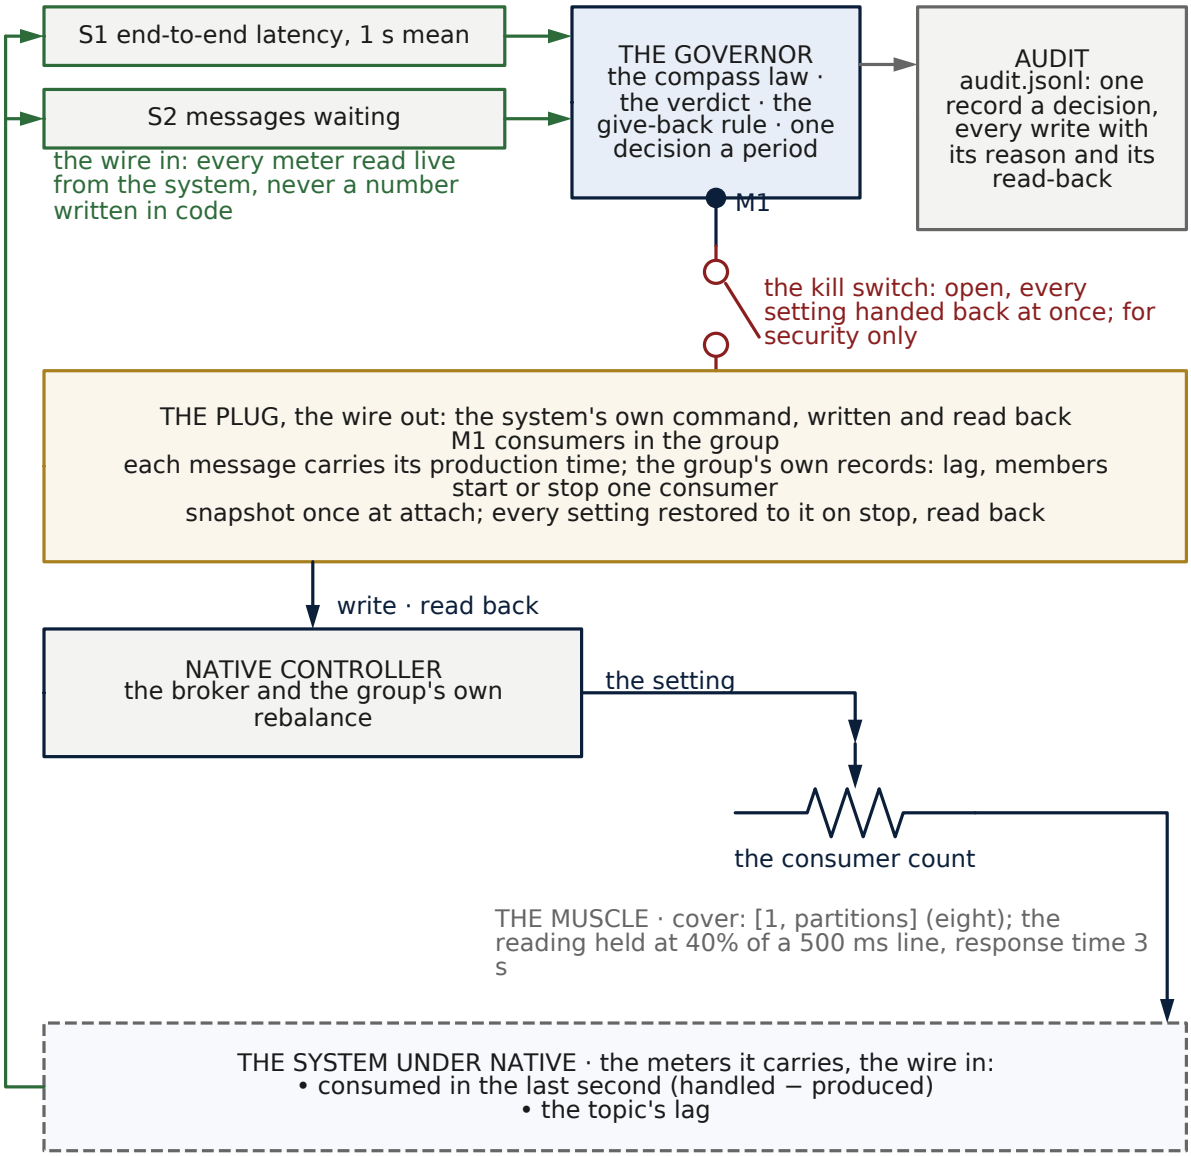

Figure 41. Wiring schematic: a message broker's consumer group. The schematic is read top to bottom as an electrical drawing: the governor (the control unit) with its sense terminals S1, S2, … on the left and its motor terminals M1, M2, … on its lower edge; the motor bus through the kill switch into the plug, the system's own command written and read back; the plug into the native controller; the native controller setting the muscle, drawn as a potentiometer with its cover; the system under native carrying the meters; and the meters back along one bus, the wire in, to the sense terminals.

The audit stands beside the governor. The senses are the end-to-end latency and the messages waiting; the one motor starts or stops one consumer. Slow with messages waiting: consumers added in proportion to the force; calm with nothing waiting: one idle consumer given back a second after a five-second dwell; at 95% of the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

line every consumer the topic can use. The rebalance every move costs is paid by Omni-Compass and counted in the gauges.

46.6 A cache's memory ceiling

Redis is wired as Ubuntu ships it, with the two settings an operator sets for a cache, a memory ceiling of 64 MB and the allkeys-lru eviction rule (`docs/REDIS_PREREGISTRATION.md`, `tools/run_redis.py`). The application in front of it is ours and declared: 1,500 requests a second from 32 threads on a Zipf working set that widens and narrows one notch at a time; a miss costs a declared 5 ms trip to the store behind the cache and a write-back. The wire in is the application's own request latency, the mean over the last second (a hit about 0.3 ms, a miss about 5.5 ms). The wire out is one setting through Redis's own console, `CONFIG SET maxmemory`, inside the cover [16, 512] MB. The compass holds the reading at 40% of a 2 ms line. Its direction rule carries the do-no-harm gate in the form this stack needs: misses grow the ceiling by notches of 8 MB **only while the cache is full** (memory used at 90% of the ceiling or more), because a miss in a cache with room to spare is a cold miss that no ceiling can mend; calm with nothing evicted in the last second gives back one notch a second, after a five-second dwell since the last growth; at 95% of the line with the cache full a quarter of the cover is added at once. One writer: a ceiling found at a value Omni-Compass did not write stops it. At the end of every omni arm the ceiling is handed back to the operator's 64 MB and read back. The memory the compass holds for a wide working set is the resource this benchmark trades and reads power given by rule; the gain is the hit rate and the work inside the line. The result (section 60.7) is exactly that shape: on all three untouched workloads the work inside the line and the hit rate rose 14% to 27% and the ceiling held rose from 64 MB to 200 to 270 MB, with the host's CPU inside the noise and every ceiling handed back.

46.7 Drone swarms: the autopilot's cruise

In gym-pybullet-drones (University of Toronto, MIT License; `docs/SWARM_PREREGISTRATION.md`, `tools/run_swarm.py`) every Crazyflie 2.x flies its shipped position controller along the planner's path at the planner's cruise: that is native. The wire in is each drone's tracking error, the distance between the drone and the point its autopilot was told to be at, on a band from 0 to a declared safe error of 0.25 m. The wire out is one knob a drone, the cruise override: the fraction of the planner's cruise the carrot moves at, never under 1.0 (the planner's own) and never over 2.0 (a quarter of the autopilot's own speed limit), moving by at most 0.01 a control tick. With slack the compass spends it as speed; as the error grows it eases; at 95% of the safe error the cruise is the planner's at once. Two guards belong to this stack: a **separation wall** (a drone with another within 0.5 m flies the planner's cruise, whatever the error reads) and the **paired physics trial** before the counted missions, which asks the simulator's own figures whether a faster mission costs less energy at all and keeps the error under the safe error; where it does not, the override is left native for that cell and the cell reads "nothing for Omni to move". Energy is a declared model from the simulator's own motor constants, said to be a model wherever it is printed; a collision voids the cell. At every landing and at the end of the run the override is handed back and read back.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

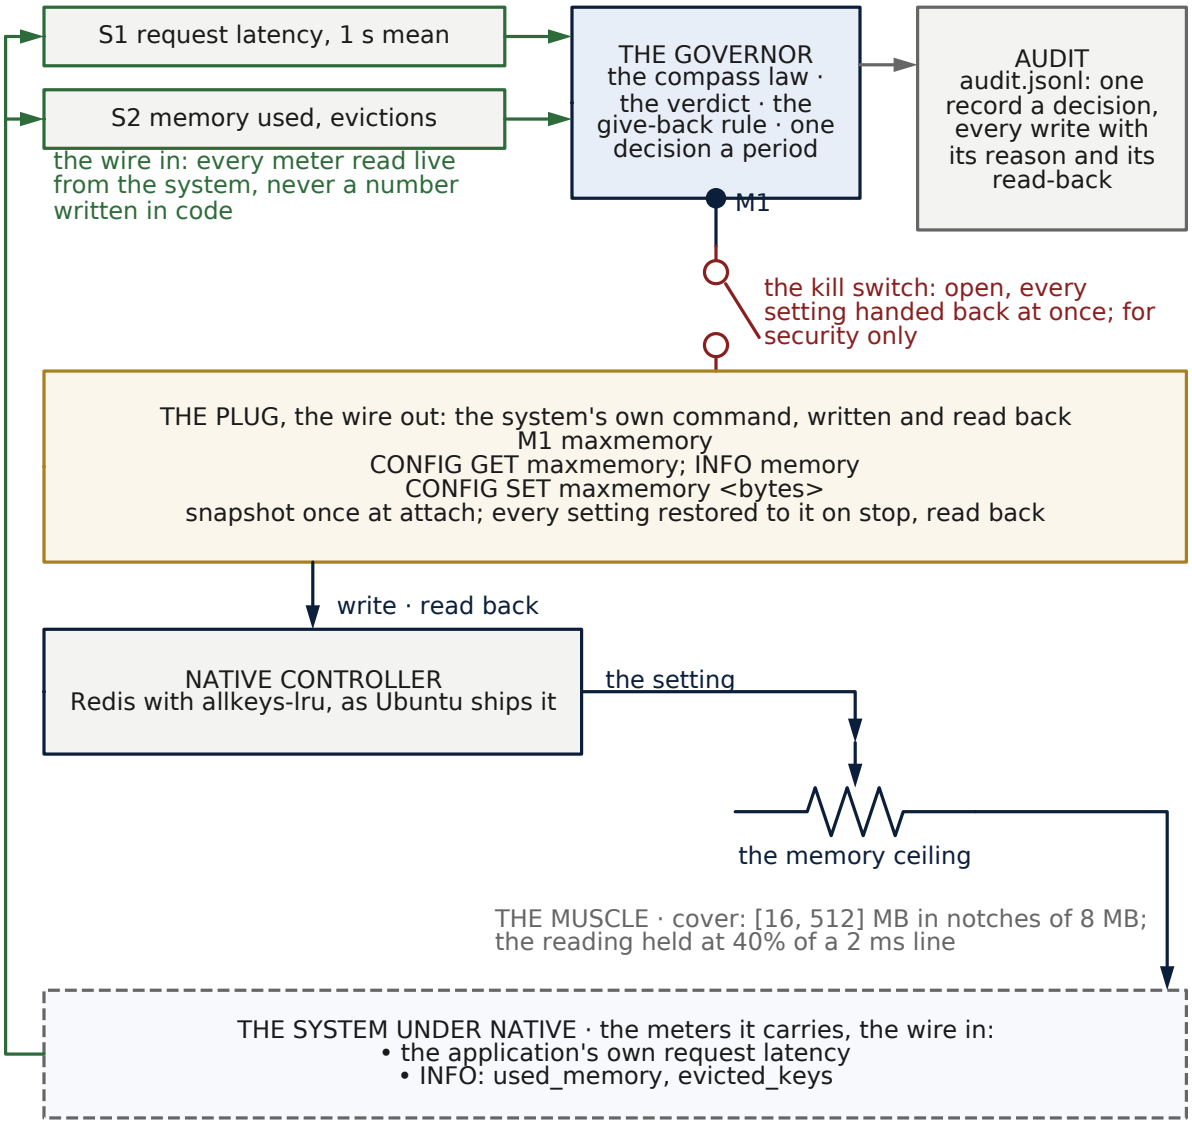

Figure 42. Wiring schematic: a cache's memory ceiling. The schematic is read top to bottom as an electrical drawing: the governor (the control unit) with its sense terminals S1, S2, … on the left and its motor terminals M1, M2, … on its lower edge; the motor bus through the kill switch into the plug, the system's own command written and read back; the plug into the native controller; the native controller setting the muscle, drawn as a potentiometer with its cover; the system under native carrying the meters; and the meters back along one bus, the wire in, to the sense terminals.

The audit stands beside the governor. The senses are the request latency and the memory used with the evictions; the one motor is maxmemory, written with CONFIG SET. Misses grow the ceiling only while the cache is full (used ≥ 90% of the ceiling); calm with nothing evicted gives one notch back a second after a five-second dwell; at 95% of the line with the cache full, a quarter of the cover.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

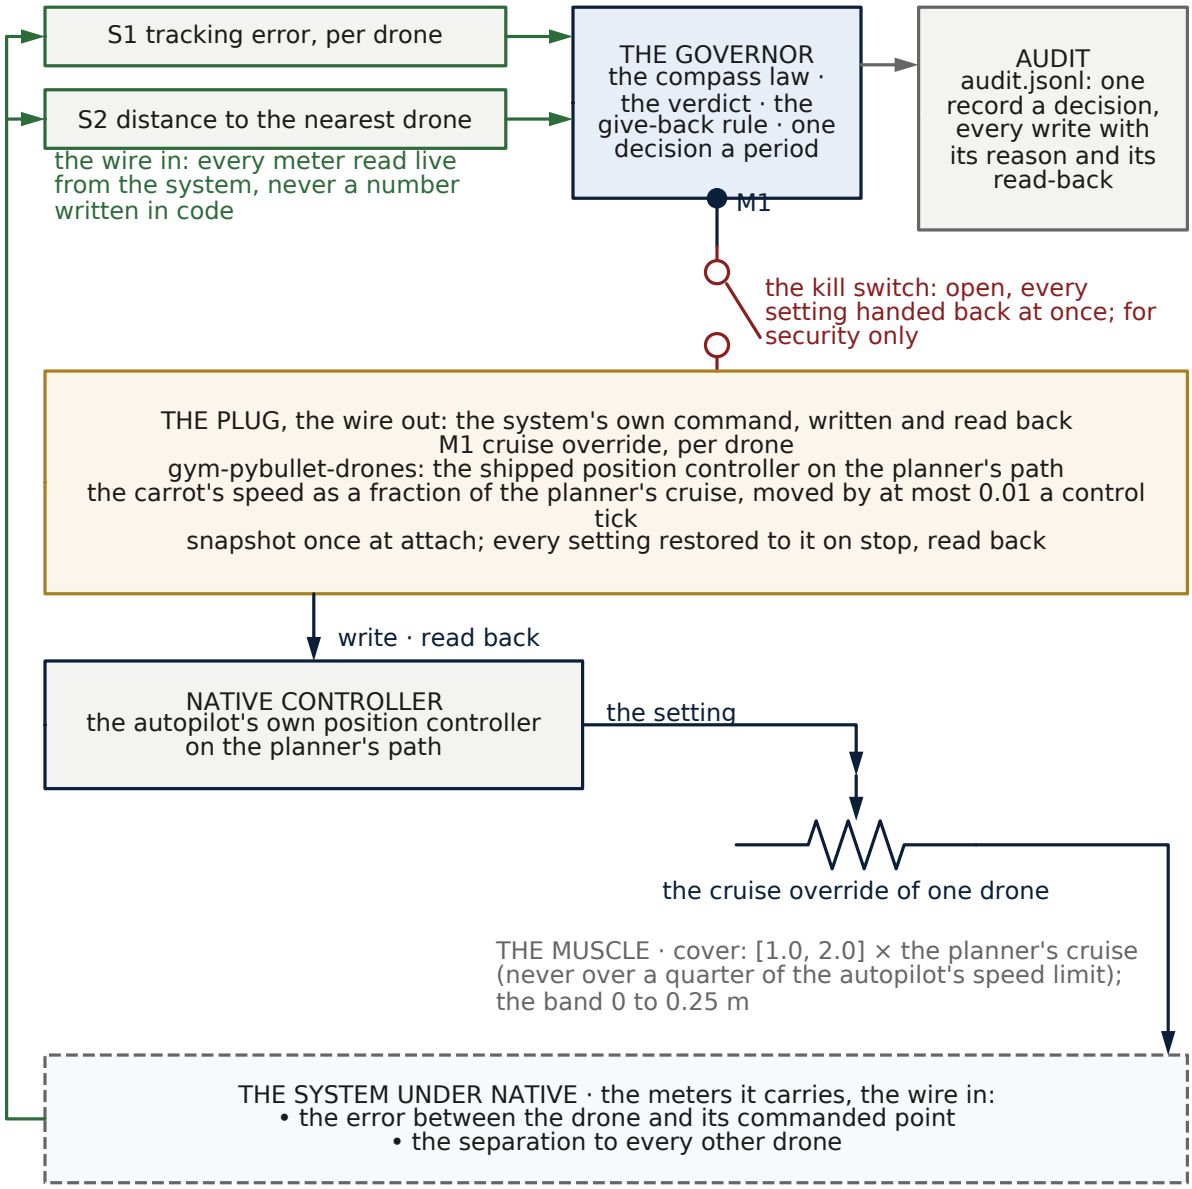

Figure 43. Wiring schematic: a drone swarm's cruise override. The schematic is read top to bottom as an electrical drawing: the governor (the control unit) with its sense terminals S1, S2, … on the left and its motor terminals M1, M2, … on its lower edge; the motor bus through the kill switch into the plug, the system's own command written and read back; the plug into the native controller; the native controller setting the muscle, drawn as a potentiometer with its cover; the system under native carrying the meters; and the meters back along one bus, the wire in, to the sense terminals.

The audit stands beside the governor. The senses are each drone's tracking error and its distance to the nearest drone; the one motor is the cruise override of one drone, a fraction of the planner's cruise moved by at most 0.01 a control tick. With slack the compass spends it as speed; as the error grows it eases; at 95% of the safe error the planner's cruise at once. The separation wall: a drone within 0.5 m of another flies the planner's cruise whatever the error reads. A collision voids the cell.

46.8 A database's storage-engine cache

MongoDB is wired as an operator runs it (`docs/YCSB_PREREGISTRATION.md`, `tools/run_ycsb.py`): the 8.0 series from its publisher's own signed repository, its configuration as shipped but for the one setting an operator sets for the storage engine, the WiredTiger cache, at 512 MB. The questions are asked by YCSB, the published cloud-serving benchmark, running its own core workloads as the project ships them, with the key space stepping one notch at a time through the cache and past it, so the working set fits the operator's cache at the low notches and outgrows it at the high ones. The wire in is the server's own mean read latency over the last second, from its `serverStatus` operation latencies, differenced. The wire out is one setting through the server's own console, `setParameter wiredTigerEngineRuntimeConfig cache_size`, inside the cover [256 MB, 2,048 MB]: the server's own floor at one end, a quarter of the machine at the other. The compass holds the reading at 40% of a 1 ms line (written as 2 ms before the first smoke run and set at 1 ms on the tuning workload's figures, as the preregistration reserved; see below). The direction rule is the cache's: slow reads grow the cache by notches of 64 MB only while the cache is full (bytes in it at 90% of its size or more), because slow reads in a cache with room to spare are not the cache's to mend; calm with no page evicted in the last second gives back one notch a second after a five-second dwell; at 95% of the line with the cache full a quarter of the cover is added at once. One writer, read-back and the hand-back at the end are the plug's, as everywhere. *Amendment 1 (8 October, declared before the second counted set): the give-back gate is now the cache's miss share, pages read into it under one percent of the pages requested from it in the last second, the MySQL test's gate, and growth is gated on missing the same way; the first set's audits showed that "no page evicted" is satisfied by every cold cache while it fills, so every burst and c arm gave four notches back in its first five seconds, before its first eviction, and then sat at the floor of the cover evicting for the rest of the arm. The memory the first set credited was that artefact, and the second set is expected to credit less, perhaps nothing beyond the noise.* Disclosed before the run: on a machine where the data files fit in the operating system's own page cache, a storage-engine cache miss is a read from memory and a decompression, not a disk read, so the gain available to this knob is smaller than it would be on a machine whose data does not fit in memory; the result will say what it is. The same plug fits any store whose engine exposes a cache size at run time (InnoDB's buffer pool, RocksDB's block cache) and any store that does not can only be sized at restart, which is not a knob Omni-Compass moves.

What the smoke runs taught, and why they are in the record. A benchmark of a cache is only a benchmark if the working set reaches the cache. Three smoke runs of the tuning workload, one repetition each and none counted, were needed before the harness asked the question it was built to ask, and each is written in the preregistration with its run number and its figures. The first failed before an arm ran, on two harness faults (a relative file path handed to a program that runs from its own directory; a server log copied as a file the upload step could not read). The second ran end to end and showed the design did not touch the cache at all: YCSB's shipped request distribution is zipfian, which concentrates almost every request on a few thousand hot records whatever the key space, so at the top notch of 1.5 million records the cache held 36 MB of its 512 MB, both arms answered inside the line with a p95 of 0.20 ms, and omni, seeing calm and nothing evicted, gave memory back to the floor of the cover. That would have read as a free memory saving for Omni-Compass, and it would

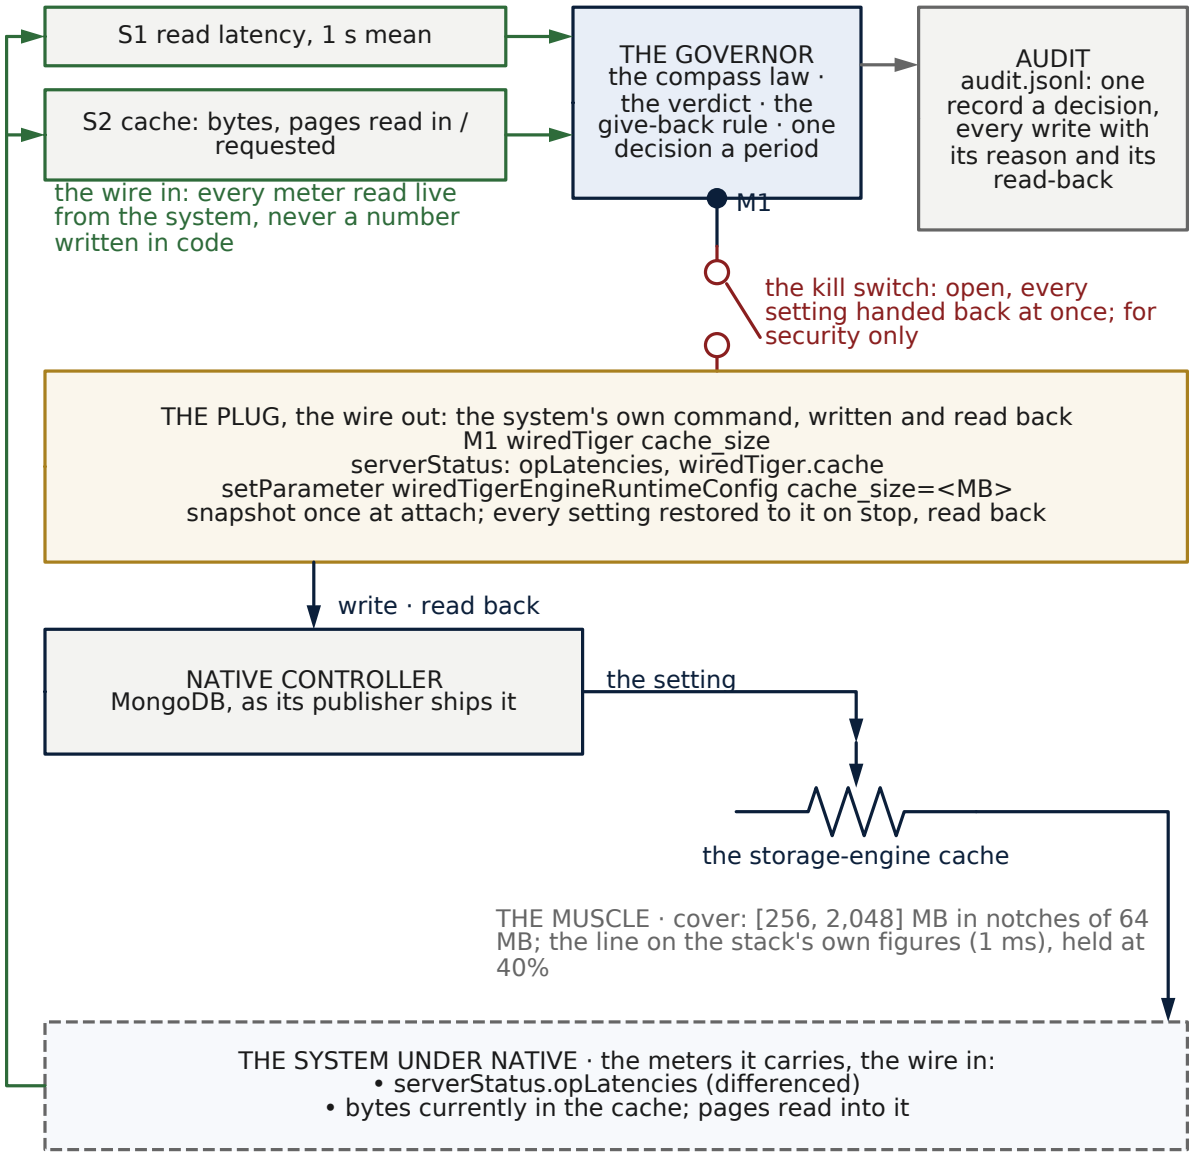

Figure 44. Wiring schematic: a database's storage-engine cache. The schematic is read top to bottom as an electrical drawing: the governor (the control unit) with its sense terminals S1, S2, … on the left and its motor terminals M1, M2, … on its lower edge; the motor bus through the kill switch into the plug, the system's own command written and read back; the plug into the native controller; the native controller setting the muscle, drawn as a potentiometer with its cover; the system under native carrying the meters; and the meters back along one bus, the wire in, to the sense terminals.

The audit stands beside the governor. The senses are the read latency and the cache's bytes with its pages read in against pages requested; the one motor is the WiredTiger cache size, written through setParameter. Grow only while the cache is full (≥ 90%) and missing (pages read in ≥ 1% of pages requested); give one notch back after a five-second dwell only while the miss share is under 1%; at 95% of the line with the cache full, a quarter of the cover.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

have been worthless: a knob with nothing to do had moved to its floor. The requests were changed to a uniform draw over the notch's key space so the working set is the key space, the one departure from YCSB as shipped, and said so. The third smoke still held 38 MB, and the per-notch figures the runner now prints showed why: the dataset was loaded with ordered keys but the run phase used YCSB's default hashed keys, so every read asked for a record that did not exist and was answered from the index alone, which fits in a few megabytes. The run phase now names ordered keys too. Nothing in the rules, the gauges or the workloads changed across the three. The fourth smoke reached the cache: native held 336 to 481 MB of its 512 MB across the notches and read 453,000 pages into it, and its per-notch figures set the line. The server's mean read latency ran 0.15 to 0.24 ms while the cache held the working set and 0.23 to 0.33 ms while it did not, with a p95 never above 0.42 ms; against a 2 ms line every one of those readings sat in the bottom quarter of the band, under the 0.4 center, so the compass could only ever read calm, the same fault as a Kubernetes line set at ten times the service's normal response. The line was set at 1 ms, the one change the preregistration had reserved for the tuning workload, with the center unchanged, so that a hit is calm and a full cache reading past 0.4 ms is slow; the one repetition's whole-arm figures (work inside the line −1.9%, cache held −31%, pages read +32%, host CPU +8%, p95 equal) are recorded and not counted. The point for a referee is the method: a result that flatters the governor is the first thing to suspect, the suspicion is pursued to a harness cause, the cause is written down with the run that showed it, a band is set on the tuning case's own figures and never on an untouched one, and the counted runs begin only when the harness provably asks the question.

46.9 A database's buffer pool, resized online in the server's own chunks

MySQL is wired as an operator runs it (`docs/MYSQL_PREREGISTRATION.md`, `tools/run_sysbench.py`): the 8.0 series from Ubuntu's own package, its configuration as shipped but for the settings an operator sets for InnoDB, the buffer pool at 512 MB (MySQL's own default is 128 MB, and the preregistration says why 512 MB is the operator's setting here), the chunk the server resizes in at its shipped 128 MB, one pool instance, and the performance schema on. The questions are asked by sysbench, the standard OLTP benchmark Ubuntu ships as its own package, running its published scripts as shipped at a fixed offered rate, with the number of tables in use stepping one notch at a time through the pool and past it. The wire in is the server's own mean statement latency over the last second, from the performance schema's statement summary, differenced. The wire out is one statement through the server's own console, `SET GLOBAL innodb_buffer_pool_size`, inside the cover [128 MB, 2,048 MB] and always in whole chunks, because that is how the server itself moves the pool. Two things about this knob differ from the MongoDB cache and the plug carries both. The server resizes asynchronously and reports its progress in its own status variable, so the plug waits for the resize to complete before reading back, and a pool found mid-resize is the server still carrying out Omni-Compass's own write, not a foreign hand. And a shrink evicts pages while the resize runs, so the dwell after any move is ten seconds rather than five. The compass holds the reading at 40% of a 0.6 ms statement line (written as 1 ms, set on the tuning workload's smoke runs, as the MongoDB line was: a hit reads 0.14 to 0.22 ms across GitHub's runners and a full pool missing a third of its reads 0.05 to 0.06 ms more, so the center sits at 0.24 ms, above the hits and under the misses); the direction rule is the cache's with one difference the smoke runs forced: slow statements grow the pool by chunks only

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

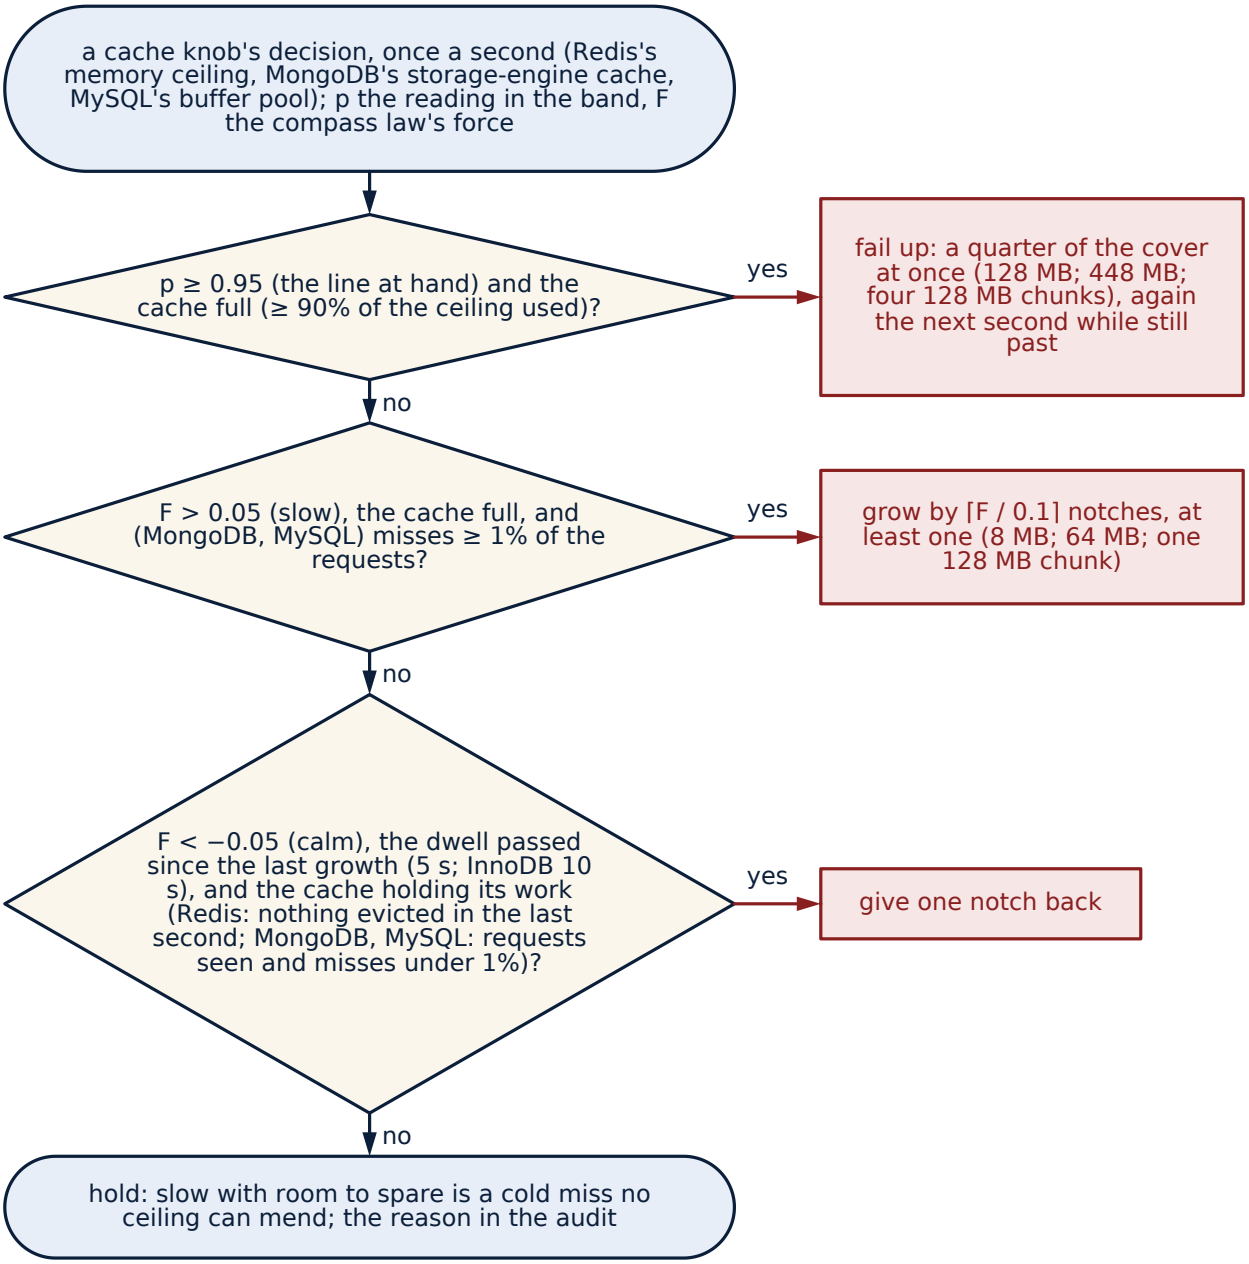

Figure 45. Flowchart: the direction rule of a cache knob (Redis, MongoDB, MySQL), once a second, tested in this order. With the reading at 95% of the line or more and the cache full (90% of its ceiling used), a quarter of the cover is added at once (128 MB; 448 MB; four 128 MB chunks), again the next second while still past. Slow (the compass law's force over 0.05) with the cache full, and for MongoDB and MySQL with misses at 1% of the requests or more, the knob grows by ⌈F / 0.1⌉ notches, at least one (8 MB; 64 MB; one 128 MB chunk).

Calm (the force under −0.05), the dwell passed since the last growth (5 s; 10 s for InnoDB) and the cache holding its work (Redis: nothing evicted in the last second; MongoDB and MySQL: requests seen and misses

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

under 1%), one notch is given back. Otherwise the knob holds, because a slow read in a cache with room is a cold miss no ceiling can mend.

while the pool is full, at 95% of the line with the pool full four chunks are added at once, and calm gives one chunk back after the dwell only while the pool's misses are under one percent of its read requests, because InnoDB keeps stale pages resident, so neither "pages free" nor "no page read from disk" ever says that a pool holds its working set, and the miss share does (amendment 2 of 8 October, declared before the third counted set: the pool also grows only while it is missing, one percent or more, the same line the other way, because the second set's audits showed 36 of read_write's 82 grows bought chunks while the pool missed under one percent of its reads, for slow writes the pool cannot mend; and no chunk is given back in a second with no read request). The work-inside-the-line gauge uses a transaction line, the statement line times the statements a transaction as sysbench's script ships it (one for a point select, fourteen for the read-only mix), and says so. One writer, read-back and the hand-back at the end are the plug's, as everywhere. The same disclosure as MongoDB's holds and is made before the run: on a 16 GB machine with a 1.4 GB dataset a pool miss is a read from the operating system's page cache, not from disk.

What the first counted set taught about this knob. Three runs of five workloads (`results/live/V3_SYSBENCH.md`, 8 October) read every gauge inside the noise, and 15 of the 45 omni arms did not read the operator's pool back at the end. The audits show the server still "withdrawing blocks" of a shrink the law had asked for when the arm ended: InnoDB withdraws the last blocks of a shrink only when the pages the load has pinned are released, so under load the withdrawal does not finish, and the server ignores a new `innodb_buffer_pool_size` while a resize is in progress, so the restore the plug issued at that moment was dropped. Every following arm began from a fresh server at the operator's setting, so no other arm was affected, and the decision loop never wrote during a resize (its writes are gated on the status); only the restore was. The plug now waits for the resize the server is carrying out (the load has stopped by then, so a stalled withdrawal finishes), writes the snapshot, and writes once more if the server ignored the first write; the receipt of that restore (what was in flight, the seconds waited, the writes, the final read-back) is in every omni arm's record and the table counts the arms. The rows of the first set stand as they are, hand-back NO included, in `docs/history/V3_SYSBENCH_set1.md`; the preregistration carries the finding and the amendment; and the second counted set, run on the amended plug the same afternoon with nothing else changed, handed the pool back on all 45 omni arms and is the result in section 60.7. The lesson is general and is the reason section 32.2 exists: a knob the device applies on its own time has to be handed back on the device's time, and the proof of the hand-back is the read-back, not the write.

All patents, copyrights and trademarks filed in the USA.

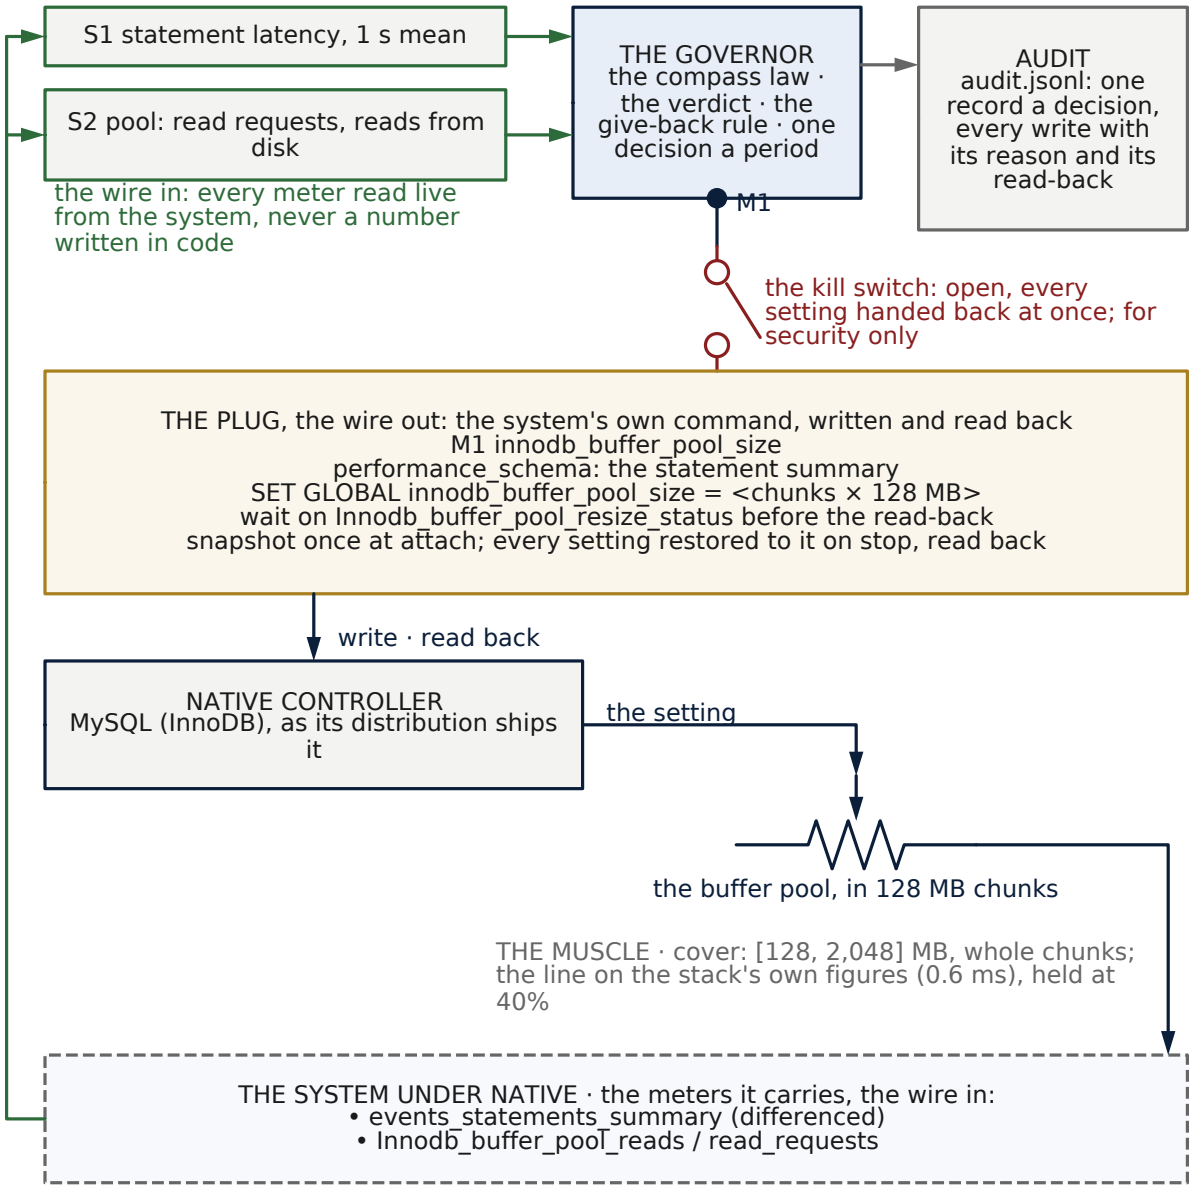

Figure 46. Wiring schematic: a buffer pool resized online in the server's own chunks. The schematic is read top to bottom as an electrical drawing: the governor (the control unit) with its sense terminals S1, S2, … on the left and its motor terminals M1, M2, … on its lower edge; the motor bus through the kill switch into the plug, the system's own command written and read back; the plug into the native controller; the native controller setting the muscle, drawn as a potentiometer with its cover; the system under native carrying the meters; and the meters back along one bus, the wire in, to the sense terminals.

The audit stands beside the governor. The senses are the statement latency and the pool's read requests against reads from disk; the one motor is innodb_buffer_pool_size, in whole 128 MB chunks. The server resizes on its own time: the plug waits for the resize before reading back, and the dwell after a move is ten seconds; the hand-back waits for the server too, writes again if ignored, and records what it waited for.

46.10 The machine itself: the kernel's frequency governor under the processor's meter

The lowest level a governor can sit on is the machine it runs on. Linux already has a controller for the processor's clock, the frequency governor (`schedutil`, or the processor driver's own), choosing the clock every few milliseconds under a ceiling the operator sets once; and the processor has its own energy meter (RAPL) ticking in microjoules. Omni-Compass sits on top of the governor exactly as it sits on the HPA: the governor keeps running, and Omni moves one knob, the frequency ceiling of every CPU, through the kernel's own files (`tools/run_cpu_power.py`, `docs/CPU_POWER_PREREGISTRATION.md`).

The reading is the service's own mean latency, held at 40% of a 20 ms line by the compass law; calm gives one notch of the ceiling back (5% of the top clock), a slow service raises it by notches, the wall puts the top on at once. Every notch down is tried on the machine itself first (section 45.4): the brain's verdict around the engine's own, eight cost samples at the deepest notch already allowed and eight one notch further, allowed only if the cost does not rise within 2%. The cost is the index's own reading for one machine (package power × latency / work inside the line), so a notch that saves less energy than it costs in speed is refused and the ceiling stays where the operator left it; a second declared objective, energy per request inside the line with the line as the guardrail, is run beside it. The snapshot of every CPU's governor and ceiling is taken once; the ceiling is handed back and read back at the end; a ceiling found at a value Omni did not write stops it; the master switch and the lease hand back if Omni dies.

The meter is the processor's own counter, class P with the caveat that it is the processor's calibrated counter and not an external meter; a smart plug on the wall socket (`WALL_METER`) adds the whole machine, read by the harness only. GitHub's own machines are virtual and expose neither the governor nor the meter: the workflow proves it with the probe on every dispatch. The benchmark runs on a machine on the metal as root, in one command (`sudo bash scripts/cpu_power_run.sh`): the founder's own tower or laptop on Linux, a rented bare-metal server, or a self-hosted runner on either. Three runs make the table (`tools/cpu_power_abc.py`). Nothing in the engine changes.

46.11 The data center under the servers: cooling, power and batteries

Under every cluster in this book stands a building. Its native controllers are older and more conservative than any autoscaler: the building management system holds the supply-air temperature through the cooling units' own loops, the chilled-water plant runs its own sequence, the uninterruptible power supply holds its reserve, the power distribution units meter every rack, and every server's management controller and every card's firmware enforce their own power limits. Omni-Compass sits on top of them exactly as it sits on the HPA. They keep running; it moves only the settings they already accept, and only inside the band the operator writes down.

What it may set, and what it never sets.

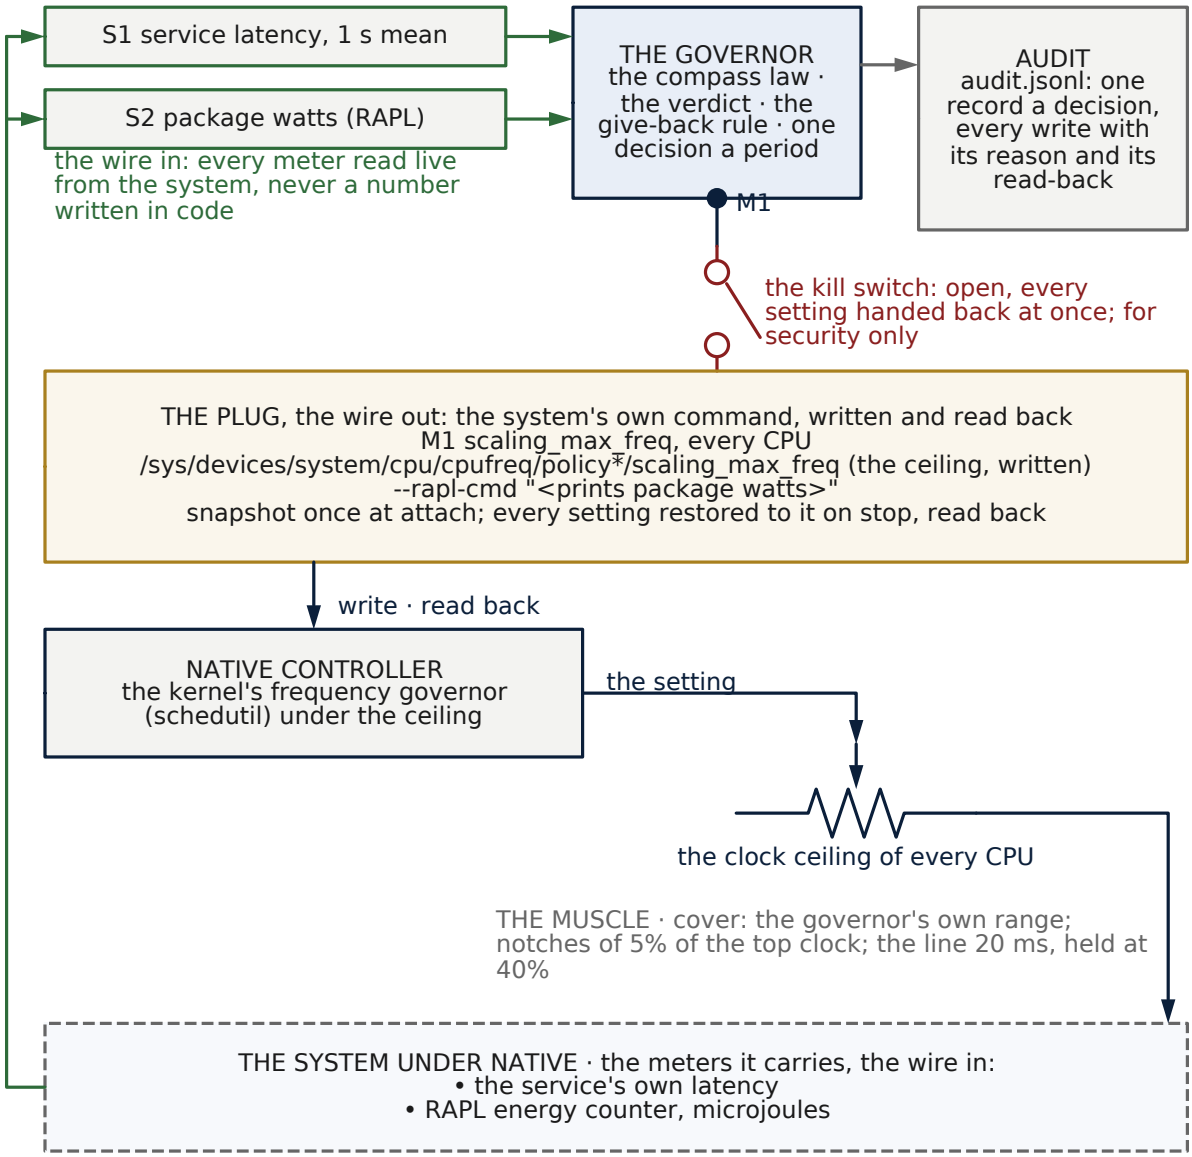

Figure 47. Wiring schematic: the machine's frequency governor under the processor's meter. The schematic is read top to bottom as an electrical drawing: the governor (the control unit) with its sense terminals S1, S2, … on the left and its motor terminals M1, M2, … on its lower edge; the motor bus through the kill switch into the plug, the system's own command written and read back; the plug into the native controller; the native controller setting the muscle, drawn as a potentiometer with its cover; the system under native carrying the meters; and the meters back along one bus, the wire in, to the sense terminals.

The audit stands beside the governor. The senses are the service's latency and the package watts from RAPL; the one motor is scaling_max_freq, the ceiling of every CPU's frequency policy. Every notch down is tried on the machine first: eight cost samples at the deepest notch allowed and eight one further, allowed only if package power × latency / work inside the line does not rise within 2%. A snapshot of every policy, restored exactly.

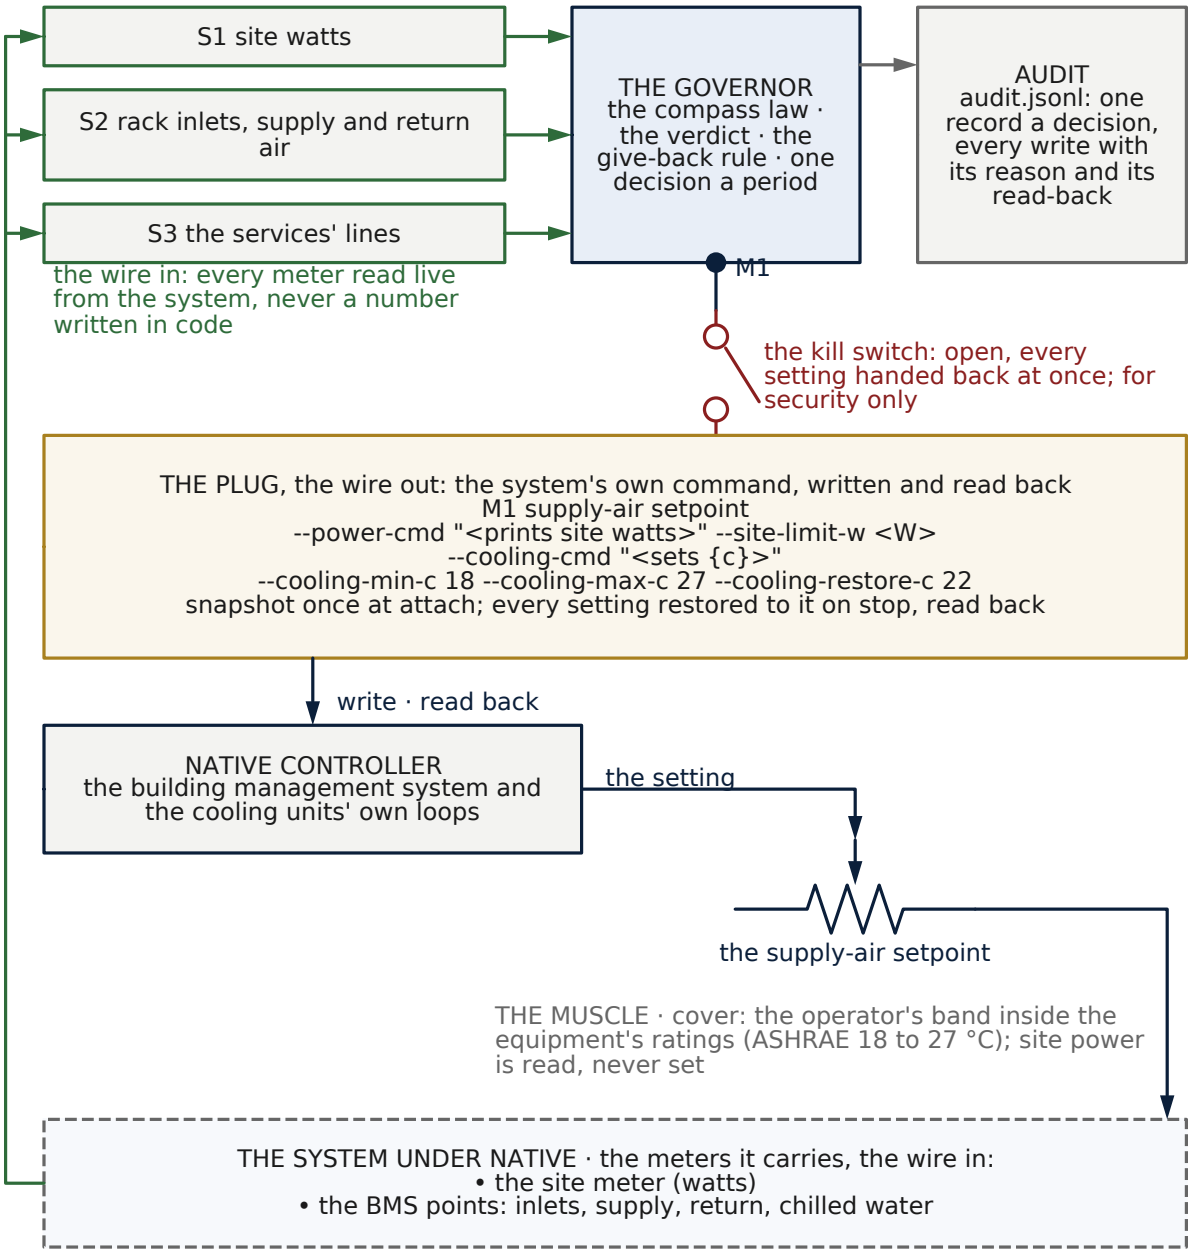

Figure 48. Wiring schematic: the data center under the servers. The schematic is read top to bottom as an electrical drawing: the governor (the control unit) with its sense terminals S1, S2, … on the left and its motor terminals M1, M2, … on its lower edge; the motor bus through the kill switch into the plug, the system's own command written and read back; the plug into the native controller; the native controller setting the muscle, drawn as a potentiometer with its cover; the system under native carrying the meters; and the meters back along one bus, the wire in, to the sense terminals.

The audit stands beside the governor. The senses are the site watts, the rack inlets with the supply and return air, and the services' lines; the one motor is the supply-air setpoint, inside the operator's band. Warmer while every reading is cool, colder as heat rises; a step allowed only where the paired trial at the site meter shows the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

site's energy no higher for the same work, every inlet inside its band and no LOSS on any service gauge. A reserve held for an outage (the UPS) is never a lever. Modelled today (class S); no live facility has run yet.

Muscle	Native controller	The knob Omni-Compass may hold	Switch	Status
Cooling	the building management system and the cooling units' own loops	the supply-air setpoint, inside the operator's band	`--cooling-cmd "<sets {c}>" --cooling-min-c --cooling-max-c --cooling-restore-c`	built (level 7)
Site power	the site's own limit and its breakers	none: site watts are read, and the site limit enters the engine as a stress	`--power-cmd "<prints site watts>" --site-limit-w <limit>`	built (level 7)
Servers' processors	the kernel's frequency governor and the processor's own limits	the clock ceiling and the power limit	section 46.10	built (level 6)
Cards	the card's firmware	the clock ceiling and the power limit	level 5	built
Uninterruptible power and batteries held as reserve	the UPS's own reserve	**none, ever**: a reserve held for an outage is never a lever (the physics criterion)		native by design
Batteries held for shifting energy	the site's dispatch	the charge window		designed as an organ, not yet wired

How the cooling muscle moves. The setpoint is moved by the heat state between the operator's minimum and maximum: a warmer setpoint while every reading is cool, which saves the chiller's energy, and a colder one as heat rises. The band must sit inside what the equipment is rated for; for most data-center equipment that is the 18 to 27 °C inlet range of the ASHRAE thermal guidelines, and inside any narrower limit the equipment's own warranty sets. The restore value is the operator's own setpoint, handed back and read back on OFF, at the end of every run, and by the lease if the governor dies.

The do-no-harm gate at the site meter. A warmer setpoint saves chiller energy only up to the point where the servers' own fans spend the saving: fan power rises steeply with inlet temperature. That is why the cooling

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

knob is judged at the site meter and not at the chiller: a step is allowed only where the paired trial shows the site's energy for the same work no higher, every rack inlet inside its band, and no LOSS on any service gauge. Where it does not, the setpoint stays the operator's, and the result says so.

Wiring it, in order.

1. **Watch.** Give Omni-Compass read access to the building management system's points (supply and return air, every rack inlet, the chilled-water temperatures) and to the site meter, and let it watch at least one full cycle of the site's demand. Nothing is written.
2. **Write the band.** The minimum, the maximum and the restore value of the supply-air setpoint, inside the equipment's ratings, signed off by the facility's engineer; the site limit in watts.
3. **The wire check** (section 42.4). The cooling command must read back the setpoint it wrote; a building schedule that rewrites the setpoint is another writer, and Omni-Compass stops writing that lever by itself (section 32.2).
4. **One hall first.** A test hall or a single row, paired against its own native weeks, before any other hall.
5. **Keep the switches in reach.** The master switch and the kill file work at the facility level exactly as at every other level.

What is measured, and what is modelled. The facility muscles are modelled today (class S): the data-hall cooling family of the catalog, the power distribution family, and the site budget shared by groups of cards, which held out with no minute over its budget (`docs/REGISTER.md`: the families of rows 29 and 38 of its catalog table, and row 20 of its benchmark table). No live facility has run yet. A class P result needs a building management system's point list, read access, a site meter and a test hall; until a facility pilot has produced its own paired receipts, this section is a wiring instruction, not a claim of savings.

CHAPTER 47

The Integration Manual

Before you wire anything: read `DISCLOSURES.md`. Omni-Compass acts only through the wires it is given; it cannot be slapped on. If your paired receipts differ from the published benchmarks in direction, the first presumption is wiring: check the installation with section 42.5 of the manual (*Wired right or wired wrong*).

Which knobs to wire in at all: `docs/WIRING_VERDICTS.md` gives every knob in every published result one of three words from the tables themselves: **write** (wire both ways), **watch** (wire out only: Omni reads, the native controller lives by itself) or **operator's choice** (a trade). A knob that showed nothing, or

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

lost, stays native. How to wire for superiority, step by step (watch first, the observation run, the brain's own verdict on each knob, the recheck): the manual, section 45.4.

How to wire Omni-Compass into your own systems yourself, from watching only to running your stack from the top. This manual ships in the box with the code and the license. Nobody from Dubra Software Inc. / The Omni-Compass LLC needs to be on site.

Read section 47.1 once, then take the levels in section 47.4 in order. Each level has a pass condition; go to the next level only when it holds. The OFF switch (section 47.2) works at every level.

47.1 What is in the box

Item	Where
The engine, nervous system, safety shield, compass and conveyance law	`omnicompass/`
The Kubernetes controller and its muscles	`omni_controller/controller.py`, `omni_controller/muscles.py`
The GPU governor (one GPU box, no Kubernetes needed)	`omni_controller/gpu_governor.py`
Container image recipe; install and permission files	`deploy/Dockerfile`, `deploy/install/omni-compass.yaml`, `deploy/rbac-*.yaml`, `deploy/pilot/`
Proof tools: paired tests on your own stack, the GPU test, our own models	`scripts/`, `tools/`, `hardware/`
Every check the code must pass	`python3 verify.py` (ends with `VERIFICATION: PASS`)
The C++ engine: every law twinned in C++20, proven equal to the Python	`cpp/` (build: `cmake -S cpp -B cpp/build && cmake --build cpp/build`)
The seal: the fingerprints that lock each Python law to its C++ twin	`results/SEAL.json`, `python3 tools/seal.py --check`
Metrics: every gauge and where it comes from	`docs/METRICS_CATALOG.md`
How it compares with what you run today	`docs/COMPARISON.md`
The license and notices	`LICENSE`, `NOTICE`

License, in short (the `LICENSE` file governs): you may download, run, modify and test Omni-Compass free of charge only to evaluate it and to reproduce its published results, including in shadow or test mode on systems you own or control (`LICENSE`, section 1). Every other use, commercial or not (running it for your

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

business or in production, selling it, hosting it, or building it into a product or service), needs a signed, paid Omni-Compass Enterprise License from Dubra Software Inc. / The Omni-Compass LLC. The copyright, patent and trademark notices, the `LICENSE`, the `NOTICE` and `DISCLOSURES.md` stay with every copy.

47.2 The rules Omni-Compass keeps on your system

1. **One OFF switch for the whole harness, in a human hand.** `python3 tools/omni_switch.py off` turns every Omni-Compass governor on the machine off at once: each returns every setting it changed to the value it recorded before it acted, reads each back and exits, and no governor starts again until `python3 tools/omni_switch.py on` (`omnicompass/master.py`; the switch file is `OMNI_MASTER_OFF`, by default `/tmp/omni-compass/OFF`; set it, and `OMNI_REGISTRY`, to a directory only the governors' user can write, `docs/THREAT_MODEL.md`). Each governor also has its own switch for one muscle at a time: creating its kill file (or setting `OMNI_KILL=1`).
   - Kubernetes controller: `--kill-file` (default `/tmp/omni.kill`).
   - GPU governor: `--kill-file` (default `/tmp/omni-gpu-kill`), or send it SIGTERM.
2. **It records before it acts.** Every original setting is written down first (annotations on the Kubernetes objects, the `snapshot` line in the GPU audit), so the OFF switch always knows what to restore.
3. **It watches before it writes.** Every level starts in watch mode: it decides and logs, and writes nothing.
4. **It never goes blind and keeps acting.** If a reading fails (nvidia-smi, metrics, the response-time feed), it returns what it changed to the recorded setting at once and gives nothing back until it can see again.
5. **Service first.** While response time is over your target, and for a few decisions after (`--slo-clear`), it may not cap power or pack tighter than your own settings.
6. **Every change is read back.** No new order goes on top of one that has not landed.
7. **The living band.** No organ is driven below 5% or above 95% of its range; machines are marked idle, never switched off by Omni-Compass; it never evicts or moves a pod.
8. **Everything is logged.** Every read, decision, write and its reason goes to the audit log (`--audit`).

47.3 Before you start: what your system needs

You run	You need
Kubernetes (any: vanilla, EKS, GKE, AKS, OpenShift/OKD, Rancher, kind)	Kubernetes 1.34 or newer (in-place pod resize); metrics-server (`kubectl top nodes` works); an HPA with a CPU target on each service to be governed; a readiness probe and a short preStop pause on each service

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

You run	You need
A response-time feed (strongly recommended at every level)	a CSV per service, `elapsed_seconds,latency_ms,ok`, written continuously; `scripts/latency_probe.py` writes one against any HTTP endpoint
NVIDIA GPUs	driver with `nvidia-smi`; root (or the capability to run `nvidia-smi -pl`); on a VM, full GPU passthrough (container or "pod" GPU rentals usually block power-limit changes)
CPU power control	Linux cpufreq with the schedutil governor (`/sys/devices/system/cpu/cpufreq`); RAPL for package watts (`/sys/class/powercap/intel-rapl`); usually bare metal only, since cloud VMs rarely expose these
Site power and cooling	a command that prints site watts, and (for cooling) a command that sets the supply-air setpoint through your building management system

Build the image once:

```
docker build -f deploy/Dockerfile -t <your-registry>/omni-compass:<tag
    ↪ > .
docker push <your-registry>/omni-compass:<tag>
```

It runs as non-root, with a read-only root filesystem and no Linux capabilities.

47.4 The levels, from watching to running the stack

47.4.1 Level 0. Evaluate without touching anything

```
pip install -r requirements.txt
python3 verify.py                       # every check; ends with VERIF
    ↪ ICATION: PASS
python3 tools/gpu_physics_sim.py        # the GPU governor against a m
    ↪ odelled NVIDIA card
python3 hardware/node_exchange.py       # CPU and GPU on one power bud
    ↪ get, modelled
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Pass condition: `VERIFICATION: PASS`. Nothing in your systems is touched.

47.4.2 Level 1. Watch (read-only)

```
kubectl apply -f deploy/install/omni-compass.yaml     # set the image
    ↪ line; it runs --mode observe
kubectl -n omni-compass logs deploy/omni-compass -f
```

- The install file grants a read-only identity. `scripts/pilot_shadow.sh` records `kubectl auth can-i` receipts that show it cannot write.
- Every decision it would take is logged with its reason; nothing is written.

Pass condition: zero writes, and readings your operators agree with.

47.4.3 Level 2. The pods, on top of your autoscalers

1. Grant `patch horizontalpodautoscalers` and `patch pods/resize` (`deploy/rbac-target.yaml`).
2. Run with `--mode target --latency-file <feed> --slo-ms <your p95 target>`.
3. Optional pod muscles, one at a time:

Muscle	Switch	What it does
convey	on with `--latency-file` and `--cap-deployments ns/name`	gives each machine's idle CPU to the serving pods on it (default: always); `--convey-on 0.5 --convey-off 0.25` engages it only while response time is over half the target
rightsize	`--rightsize-deployments ns/name`	each pod's CPU request follows its measured use × (1 + headroom), in place
coldstart	`--coldstart-deployments ns/name --coldstart-signal ns/configmap`	scales a service to zero while no work waits, wakes it the moment work arrives
batch	`--batch`	admits held Jobs labelled `omnicompass.io/batch=true` when there is load and power headroom
batch pace	`--batch-pace`	pauses Jobs labelled `omnicompass.io/pausable=true` under power or heat stress, resumes them after
rollout guard	`--rollout-guard ns/name`	pauses a rollout while change is not permitted, undoes one past its deadline when rollback is authorised

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Muscle	Switch	What it does
contain	`--contain-namespaces ns --contain-cpu-m <m>`	holds an agent namespace to a CPU budget with a quota
security hold	`--security-configmap ns/name`	key `hold: "true"` blocks every expansion

Your HPAs keep scaling as before. Omni-Compass sets their targets and raises floors ahead of bursts.

Pass condition: p95, p99 and failed requests never behind than your own, over paired runs (section 47.6).

47.4.4 Level 3. The machines

1. Grant `patch nodes` and `patch pods` (`deploy/kind/rbac-omni.yaml`).
2. Run with `--mode nodepool --active-nodes-only --closure /app/law/closure.json --node-scale-cmd "<command with {n}>"`.

Your platform	The park/wake command
any cluster, bare metal, kind	`bash scripts/kind_nodepool.sh {n}`: close machines to new work and mark them first to go; open again, warm machines first
Karpenter / EKS Auto Mode	the NodePool CPU limit at `{n} × node CPU`, parked nodes kept, not consolidated away
Cluster Autoscaler node group	the group's desired size, scale-down through parking, not deletion
OpenShift / OKD	the worker MachineSet replicas, parked, not deleted

A machine is given back only when every sense is live, the last order landed, pods are not scaling up, nothing waits for a place, and the remaining machines stay inside the band.

Pass condition: fewer machines in service and less energy, with no LOSS on any service gauge.

47.4.5 Level 4. Omni-Compass decides; Kubernetes is the muscle

Add `--strict-replicas`: Omni-Compass decides each service's replica floor and when to shrink; your HPA stays as the fast reflex upward; the node law sizes the machines.

Pass condition: as level 3.

47.4.6 Level 5. A GPU box (with or without Kubernetes)

The GPU governor runs on any Linux machine with NVIDIA GPUs:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
# watch: decides and logs, writes nothing
sudo python3 -m omni_controller.gpu_governor --mode watch --gpus 0,1,2
    ↪ ,3 --audit /var/log/omni/gpu.jsonl \
     --latency-file <feed> --slo-ms <p95 target>
# cap: writes the power limits
sudo python3 -m omni_controller.gpu_governor --mode cap   --gpus 0,1,2
    ↪ ,3 --audit /var/log/omni/gpu.jsonl \
     --latency-file <feed> --slo-ms <p95 target>
# OFF
sudo touch /tmp/omni-gpu-kill
```

What it does, every `--interval` seconds (default 2):

- reads each GPU's own meter: power draw, temperature, utilization, power limit;
- the engine sets a power cap; the shield keeps it above `--min-share` × the start limit (0.70) and above draw × (1 + `--headroom`);
- a busy card (smoothed utilization at or over `--util-gate`, 0.5) gets its full limit back at once;
- a response-time breach or a failed reading returns the start limit at once.

Speed lock (optional). Keep every response-time gauge at least `--speed-gain` (1%) faster than without Omni-Compass, and spend any speed won elsewhere on watts:

```
python3 tools/gpu_baseline.py baseline.json native-run/latency.csv
    ↪  # a run without Omni-Compass, other days
sudo python3 -m omni_controller.gpu_governor --mode cap --baseline-fil
    ↪ e baseline.json --latency-file <feed> ...
```

Prove it on your card: `sudo bash scripts/gpu_paired.sh` runs native, watch and Omni-Compass back to back on the same machine and prints the table and verdict (`docs/GPU_RUN_GUIDE.md`).

Pass condition: work per energy up, and requests served and p95 inside the guardrails.

47.4.7 Level 6. CPU clock and power

Add to the Kubernetes controller, on bare metal:

```
--cpufreq-policy-root /sys/devices/system/cpu/cpufreq --cpufreq-requir
    ↪ e-schedutil \
--rapl-cmd "<prints CPU package watts>"
```

The CPU frequency ceiling follows the engine's cap inside the nervous system's envelope; the OFF switch writes every policy's recorded maximum back exactly. GPUs can be wired the same way from the controller: `--gpu-query-cmd "nvidia-smi --query-gpu=power.draw,temperature.gpu`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

`--format=csv,noheader,nounits" --gpu-power-cmd "nvidia-smi -pl {w}" --gpu-max-w <max>`.

Pass condition: energy per unit of work down, no LOSS on any service gauge.

47.4.8 Level 7. Site power, cooling, batteries

Organ	Switch	Status
site power stress	`--power-cmd "<prints site watts>" --site-limit-w <limit>`	wired: power stress enters the engine; batch pace and caps respond
cooling setpoint	`--cooling-cmd "<sets {c}>" --cooling-min-c 18 --cooling-max-c 27 --cooling-restore-c 22`	wired: warmer supply air while cool, colder as heat rises
CPU + GPU on one power budget	`hardware/node_exchange.py` (the conveyance law over CPU and GPU organs)	**modelled only (class S).** The live levers exist (levels 5 and 6); the exchange between them has not run on hardware
GPU groups sharing a site budget	`hardware/site_exchange.py`	**modelled only (class S)**
on-site batteries as an organ	designed (`docs/DOMAIN_MAP.md`)	**not built**

47.5 Stack by stack

Stack	Levels available	Notes
Vanilla Kubernetes, kind, Rancher	1-6	as written
Amazon EKS	1-5	nodes via Cluster Autoscaler node group or Karpenter NodePool (level 3 table); CPU power control is not exposed on EC2 VMs; GPUs on bare-metal or full-GPU instances
Google GKE, Azure AKS	1-5	as EKS, with the provider's node-pool size as the park/wake command
Red Hat OpenShift / OKD	1-5	OpenShift is Kubernetes underneath; grant the same permissions through a Role; machines via the worker MachineSet

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Stack	Levels available	Notes
NVIDIA GPU servers without Kubernetes	5	the GPU governor alone
Bare-metal CPU servers	6	cpufreq and RAPL through sysfs
Slurm / HPC schedulers	5 on the GPU nodes	a Slurm connector for job-level decisions is not built
Building management (cooling, power meters)	7	through your BMS's command line or API, wrapped in the command templates
Azure AKS, the bill as the gauge	1-3	Azure's managed cluster autoscaler stays native and deletes the machines Omni-Compass idles; one or several work pools (`worker_pools`), the replica ceiling raised with the fleet (`hpa_max`); a fleet of 4 cannot show a saving of one machine, 39 can (manual, section 46.1; `docs/AZURE_SETUP.md`)
PostgreSQL behind PgBouncer, or any pooler with a console	one knob	the pool size through the pooler's own admin console, cover [2, 90], one writer, restored on OFF (manual, section 46.2; `docs/POSTGRES_PREREGISTRATION.md`)
Apache Kafka, or any consumer group an operator sizes	one knob	the consumer count inside [1, partitions], the group's own end-to-end latency as the reading, the rebalance paid on every move, handed back on OFF (manual, section 46.5; `docs/KAFKA_PREREGISTRATION.md`)
Redis, or any cache with a console and a memory ceiling	one knob	`maxmemory` through the cache's own console, cover [16, 512] MB, grown only while the cache is full (a cold miss is not the ceiling's), one writer, restored on OFF (manual, section 46.6; `docs/REDIS_PREREGISTRATION.md`)
Drone swarms (gym-pybullet-drones; PX4 and ArduPilot next)	one knob a drone	the cruise override inside the autopilot's limits, a separation wall, the paired physics trial, collisions void the cell (manual, section 46.7; `docs/SWARM_PREREGISTRATION.md`)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

Stack	Levels available	Notes
MongoDB, or any store whose engine exposes its cache size at run time	one knob	the storage-engine cache through the server's own console, cover [256, 2,048] MB, grown only while the cache is full, one writer, restored on OFF (manual, section 46.8; `docs/YCSB_PREREGISTRATION.md`)
MySQL, or any store whose engine resizes its buffer pool online	one knob	the InnoDB buffer pool through the server's own console (`SET GLOBAL innodb_buffer_pool_size`), cover [128, 2,048] MB in the server's own 128 MB chunks, grown only while the pool is full, the plug waiting for the server's asynchronous resize before reading back, one writer, restored on OFF (manual, section 46.9; `docs/MYSQL_PREREGISTRATION.md`)
A rented cloud machine running the big organisms	the whole harness	`big-organism-detached`: start, collect, survey; the clock rule sets the window (`.github/workflows/big-organism-detached.yml`)
Independent simulators (CityLearn, pandapower, MuJoCo)	one knob each	the simulator's own controller is native; preregistered, A/B/C (manual, section 46.3)
The machine itself: Linux's frequency governor under the processor's meter	one knob	the frequency ceiling of every CPU through the kernel's own files, cover [half the top clock, the top], the governor still running under it; every notch down tried on the machine first by the brain's verdict; energy from RAPL and a wall plug where fitted; root on a machine on the metal, never a virtual one (manual, section 46.10; `docs/CPU_POWER_PREREGISTRATION.md`; `sudo bash scripts/cpu_power_run.sh`)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

47.6 Proving it on your own system

1. **Paired runs.** Run your service the same way twice, once as you run it today and once with Omni-Compass on top, back to back on the same machines, order rotated, at least 5 times (10 for a result you publish). `scripts/kind_paired.sh` and `tools/live_reps.py` do this and print each gauge with its 95% interval. A change is proven only when its interval excludes zero.
2. **The switch drill,** after every run: turn Omni-Compass OFF, check every setting is back at its recorded original and no `omnicompass.io/*` annotation remains, turn it ON.
3. **Read the results** with `docs/METRICS_CATALOG.md`: every gauge says whether it is measured or modelled.

47.7 Reading the log

Line	Meaning
`gate: a sense is blind`	a reading failed; nothing is given back until it returns
`gate: pods scaling up`	pods first, machines after
`decision failed (n in a row)`	the cluster could not be reached; nothing was written. Turn it OFF for native at once
`convey: <machine> idle CPU to its k serving pod(s), limit c`	that machine's idle CPU now reaches the work on it
`convey: response time calm, operator's limit`	the pods are back at your own CPU limit
`busy gate: utilization u, the limit read at start`	a busy GPU got its full power limit back
`speed lock: worst ratio r vs line 0.99 (spend / hold / release)`	the speed lock's reading and what it did
`response-time reflex: the limit read at start`	response time went over target; full power at once
`reset: the limit read at start`	the OFF switch restored this setting

47.8 What is shown, and of what kind

Claim	Evidence	Kind
On real Kubernetes, Omni v1 (an engine that no longer stands;	`results/live/V1_ALL_FOUR.md`, `V1_STEADY.md`,	measured on kind; read by the three-run rule

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Claim	Evidence	Kind
omni-v25's record is `results/OMNI_INDEX.md`), three runs of ten pairs each: more work inside the response line (up 42% to 48%), the 95th percentile down 56% to 69% (faster answers), machines in service down where a paired trial allowed it (steady down 1.5% to 3.4%, batch down 15% to 24%), each GAIN in all three of our runs	`V1_WANDERING.md`, `V1_FAULTS.md`, `V1_BATCH.md`, `V1_FAIRNESS.md`	(`docs/OMNI_V1.md`)
On a real database, Omni v3 (an engine that no longer stands; omni-v25's record is `results/OMNI_INDEX.md`), its last counted set: on `tpcb_hot` the connections held open for the same work cut 7% to 13%, GAIN in all three of our runs, with the host's CPU STEADY (the first counted set's 61% to 63% cut and its CPU cost, up 14% to 27%, power given, traced to the harness's own launches, are kept in `docs/history/V3_PGBENCH_set1.md`)	`results/live/V3_PGBENCH.md`	measured on GitHub's machines
On Azure's bill, 4 workers: no difference beyond the noise on any gauge (the fleet is too small for the lever)	`results/live/V1_AKS_STEADY.md`, `V1_AKS_BURST.md`	a real bill
Energy on Kubernetes	declared model on kind, no meter	modelled
GPU: more work per energy within the speed guardrail	the run of 2 October on an earlier card controller, obsolete; the runs on rented cards since (`results/gpu/`): on one A10 on omni-v23 the energy for each request served down 0.8% to	the card's own meter

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Claim	Evidence	Kind
	1.8%, GAIN in all three of our runs (`results/gpu/V23_A10_CAP_FULL_ABC.md`)	
CPU and GPU on one power budget: more work, never over the budget	`results/hardware/NODE_EXCHANGE_*.json`	modelled
Safety: OFF switch restores everything; watch mode writes nothing	every live run's switch drill; `verify.py`	measured / checked

47.9 Python, C++ and the seal

Omni-Compass exists in two languages. The laws are twinned: each has a Python version and a C++20 version that give the same answers, proven by a parity test on every build.

Law	Python	C++	Proven by
core engine (six-state equations)	`omnicompass/core.py`	`cpp/src/core.cpp`	500 frozen fixtures
governor (allocation laws)	`omnicompass/adapter.py`	`cpp/src/governor.cpp`	`tests/test_cpp_governor_parity.py`
safety shield	`omnicompass/shield.py`	`cpp/src/shield.cpp`	`tests/test_cpp_shield_parity.py` (plus adversarial cases)
HPA replica law	`fleet/harness.py`	`cpp/src/hpa.cpp`	`tests/test_cpp_hpa_parity.py`
closure law (machines)	`omnicompass/closure.py`	`cpp/src/closure.cpp`	`tests/test_cpp_closure_parity.py`
conveyance law (the conserved budget)	`omnicompass/conveyance.py`	`cpp/src/conveyance.cpp`	`tests/test_cpp_conveyance_parity.py` (identical to the last bit)
nervous system (authority per organ, living band)	`omnicompass/nervous_system.py`	`cpp/src/nervous_system.cpp`	`tests/test_cpp_twins_parity.py`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Law	Python	C++	Proven by
compass and ledger (composite storage)	`omnicompass/compass.py`, `omnicompass/storage.py`	`cpp/src/compass.cpp`	`tests/test_cpp_twins_parity.py`
GPU governor rules (shield limit, busy gate, speed lock, window, baseline)	`omni_controller/gpu_governor.py`	`cpp/src/gpu_rules.cpp`	`tests/test_cpp_twins_parity.py`

The seal (`results/SEAL.json`) holds the SHA-256 fingerprint of every file of every twin, written only after all parity tests pass (`python3 tools/seal.py`). `verify.py` fails if any sealed file changes afterwards, and names it. So the Python and the C++ cannot drift apart unnoticed. What stays in Python is the plumbing that talks to Kubernetes, nvidia-smi and sensors (`omni_controller/controller.py`, `muscles.py`, the device I/O of `gpu_governor.py`) and the model harnesses; every decision they take goes through the twinned laws. The seal lists them as Python only.

Keep this manual with the code. When Omni-Compass changes, this manual, the C++ twin and the seal change in the same commit.

CHAPTER 48

Running the GPU Benchmark

48.1 Running the GPU test yourself, step by step

> **Before you wire anything:** read `DISCLOSURES.md`. Omni-Compass acts only through the wires it is given; it cannot be slapped on. If your paired receipts differ from the published benchmarks in direction, the first presumption is wiring: check the installation with section 42.5 of the manual (*Wired right or wired wrong*).

There are three ways to get real-machine numbers:

- **Your own tower:** a machine you control, with a smart plug measuring the whole machine at the wall (section A).
- **GitHub's GPU machines:** they run the test from the repository with one click (section B).
- **A rented cloud GPU:** sections 48.1.4 to 48.1.9.

48.1.1 Your own tower, measured at the wall

You need:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- an NVIDIA graphics card (a GeForce RTX works);
- Linux on that machine (a spare drive or a USB boot is fine);
- a smart plug that reports watts, for example a Shelly Plus Plug or any plug running Tasmota, which cost about $20 to $30.

Plug the tower into the smart plug, and connect the plug to your home Wi-Fi with its own app. Note its IP address, shown in the app or on your router's device list. Then on the tower:

```
python3 tools/wall_meter.py shelly2:192.168.1.50 --once       # print
    ↪ s the tower's watts right now
sudo WALL_METER=shelly2:192.168.1.50 bash scripts/gpu_paired.sh
    ↪           # trial run
sudo WALL_METER=shelly2:192.168.1.50 PHASE=confirm bash scripts/gpu_pa
    ↪ ired.sh    # the real test
```

Use `shelly1:` for older Shelly plugs and `tasmota:` for Tasmota plugs. The table then adds whole-machine energy at the wall and requests served per wall kilojoule. The plug is read by the test only; Omni never sees it, so its number is independent of Omni.

48.1.2 GitHub's own GPU machines

1. **One-time setup, by an owner of the Omni-Compass organisation on GitHub:**
   1. Go to **Settings → Actions → Runners → New runner → New GitHub-hosted runner**.
   2. Choose the image **NVIDIA GPU-Optimized Image for Linux** and a GPU size.
   3. Name its label `gpu-t4`, or set the repository variable `GPU_RUNNER` to the label you chose.

GPU runners are billed per minute on paid plans.

2. **To run:** go to **Actions → gpu-bench → Run workflow**, then choose `smoke` or `confirm`.
3. **Results:** each repetition runs on its own GPU machine. The results are pooled into one table, shown on the run's summary page, and every raw file is committed back to the branch under `results/gpu/github-<run id>/`.

If GitHub's machines don't allow changing the GPU power limit, the job stops in its first minute and says so.

48.1.3 A rented cloud GPU

This costs roughly $10 to $25 in rented GPU time. You type a handful of commands; the machine does the rest. The same test on Lambda from one GitHub button (it rents the machine, checks the keys first at no cost, brings the results back and always gives the machine back) is `docs/LAMBDA_SETUP.md`.

48.1.4 Rent the right kind of machine

The test changes the GPU's power limit, so you need a machine where you are the full administrator of the GPU:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Use a virtual machine (VM) or a bare-metal server.** Lambda Cloud "on-demand instances" are VMs; so are the GPU instances on AWS, Google Cloud and Azure.
- **Avoid "container" or "pod" rentals.** Their GPUs usually block power-limit changes. This is common on the cheapest per-hour marketplaces.
- **Any single NVIDIA data-center GPU works:** A10, L4, A100, H100, L40S. One GPU is enough.
- **Choose an image that already has PyTorch.** On Lambda that is the default "Lambda Stack" image.

You don't have to guess whether a machine allows it. In its first minute the test checks, and stops with *"cannot set the power limit (run as root)"* if the machine doesn't allow it. If you see that, shut the machine down (you pay only for the minutes used) and rent a different kind.

48.1.5 Connect to it

The rental site shows a command like `ssh ubuntu@123.45.67.89`. Paste it into Terminal (Mac) or PowerShell (Windows).

48.1.6 Get the code

On the rented machine (the repository is public while the benchmarks run; if it is private, use a read-only fine-grained token in the URL):

```
git clone https://github.com/The-Omni-Compass-LLC/The-Omni-Compass-LLC
    ↪  the-omni-compass
cd the-omni-compass
git log --oneline -1       # the commit you are about to test; write i
    ↪ t down
pip install -r requirements.txt

nvidia-smi                 # should show your GPU
```

48.1.7 The whole test, one command (about 36 hours)

```
sudo nohup bash scripts/gpu_rented_run.sh > run.log 2>&1 &
tail -f run.log            # Ctrl+C stops watching; the test keeps run
    ↪ ning
```

It runs, in order, and stops at the first failure:

1. the machine check (one copy only, nothing else on the card, the card's default limit and clock range restored);
2. the **wire check**, which must end `WIRED RIGHT` (manual, section 42.4);
3. the smoke test, about 40 minutes, never counted;

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

4. the preregistered counted run on compute-bound work: 10 repetitions × native / watch / Omni, 600 s each, about 6 hours;
5. the second preregistered counted run on AI token generation (memory-bound), the same design, about 6 hours (`SKIP_DECODE=1` skips it); each is its own result, never pooled. Both are packed into one file as soon as they finish: `results/gpu/omni-gpu-<stamp>-confirmations.tar.gz`;
6. **an operator's power cap underneath** (70% of the card's default limit): the cap alone vs the cap with Omni-Compass on top, at the usual load and fully loaded (more work from the same watts), about 3 hours (`SKIP_CAP=1` skips it);
7. **the GPU fault drill**, about 10 minutes: the governor killed outright, the master switch pulled, the response feed blind; every check must pass (`SKIP_DRILL=1` skips it). Everything so far is then packed into `results/gpu/omni-gpu-<stamp>-partial.tar.gz`;
8. the seven organisms with this card inside, each as **1, 10 and 100 copies** on one clock (5, 3 and 2 repetitions; no 1,000 copies, the founder's order of 12 October, amendment 13), at least 16 hours (60 paired repetitions, each arm 240 steps of 2 s); a size whose step needs longer than 2 s gets a longer step, measured on the machine and stated in the receipt (`SKIP_HIL=1` skips this stage);
9. **real AI serving** last: a small open language model served by vLLM, about 2 hours (`SKIP_LLM=1` skips it); if vLLM cannot install on the machine, the stage says so and nothing before it changes;
10. one packed file: `== send this one file back: results/gpu/omni-gpu-<stamp>.tar.gz`, with the label each table chose by rule.

To stop everything at any moment: `sudo python3 tools/omni_switch.py off` turns every Omni-Compass governor off and hands the card back to its own settings.

Do not start it twice and do not use the card for anything else while it runs.

48.1.8 Bring the results back

Download `results/gpu/omni-gpu-<stamp>.tar.gz` (in JupyterLab: right-click, Download; or `scp` from your own computer). It holds every raw reading, every table, the verdict and the checksums. **Then shut the rented machine down** on the rental site, so the billing stops.

48.1.9 Read it before you believe it

Open `results/gpu/run-<stamp>/GPU_REPS.md` and check the rows of the manual's section 42.5 (*Wired right or wired wrong*): watch equal to native, requests equal, the card's busy clock under Omni at or above its own, the lid while busy at or above its own busy draw, fail-up rare in the credit-per-write table. If a row reads wired wrong, the run says nothing about Omni-Compass until the wiring is fixed (`DISCLOSURES.md`, section 3).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

48.1.10 The 8-GPU result: every card of one server at once

The same test as section C, on a machine with several cards (Lambda "8x A100" or "8x H100", a VM, the Lambda Stack image). Every card runs its own paired test at the same moment, sharing the server's power supply, cooling and neighbours' heat, as in a real data center. Each card starts its arm rotation one step later than the card before it, so at any moment some cards run native and some run Omni-Compass.

Get the code as in step 3, then:

```
sudo nohup bash scripts/gpu_8card.sh > run8.log 2>&1 &
tail -f run8.log
```

Each card: wire check, envelope, smoke, the compute counted run, the AI token generation counted run, the operator's power cap underneath (about 15 to 16 hours, all cards together). Then the fault drill once on card 0, with every other card idle. Then one pooled table per workload (every repetition of every card, each paired within its own card: 80 repetitions per workload on 8 cards) and each card's own table. `SKIP_DECODE=1 SKIP_CAP=1` runs the compute counted run alone, about 6.5 hours. **Every 8-GPU run has a hard time budget** (`MAX_HOURS`; by default 10.5 hours with `POOLED=1`, 4 with `FAST=1`, 26 for the whole design): at the budget the master switch hands every card back, the stages still running stop, and what finished is packed and printed as the file to send back. Lambda bills until the instance is terminated, so terminate it when that line appears. `sudo POOLED=1 nohup bash scripts/gpu_8card.sh &` **runs every stage with the repetitions pooled across the cards (3 per card per counted run, 24 per test on 8 cards; 2 per power cap load; 1 per organism size), about 9 to 10 hours.** `sudo FAST=1 nohup bash scripts/gpu_8card.sh > run8.log 2>&1 &` is a short look, about 3.5 hours: 3 repetitions per card (24 on 8 cards), then one model across every card; it leaves AI token generation, the power cap and the whole stacks out, so it is never the result to show. Last, the whole server as one: a language model (Qwen2.5-7B-Instruct, open) served across every card at once by vLLM, one Omni-Compass governor per card, the server's total GPU energy, about 2 hours (`SKIP_LLM=1` skips it). Before it, **the whole stacks with a real card inside**: the seven organisms at 1, 10 and 100 copies (no 1,000 copies, amendment 13), native and Omni, the full repetitions (5, 3, 2 by size), each organism on its own card at the same time, so the stage that takes at least 16 hours on one card takes the time of its longest organism, about 3 hours (`SKIP_HIL=1` skips it). The whole design, every stage: about 20 to 22 hours. Progress: `tail -f results/gpu/8card-<stamp>/card-*.log`. At the end: `== send this one file back: results/gpu/omni-8card-<stamp>.tar.gz`. The master switch (`sudo python3 tools/omni_switch.py off`) stops every card's governor at once.

48.1.11 Your own serving engine

own vLLM? Start it as you always do, then:

```
sudo LLM_URL=http://127.0.0.1:8000 LLM_MODEL=<your model name> GPU=0 E
    ↪ NVELOPE=<envelope.json> OUT=results/gpu/mine \
  bash scripts/gpu_vllm.sh
```

The same paired test (your engine alone against your engine with Omni-Compass on top) runs against it; nothing is installed or started. `GPU=0,1,2,3,4,5,6,7` when your engine spans several cards. Make the envelope once with `python3 tools/declare_envelope.py envelope.json --gpu 0`.

48.1.12 Whole-server power from the server itself

The bench records the whole machine's watts beside the cards' own when you give it a meter: `WALL_METER=redfish:<BMC address>` (with `REDFISH_USER` and `REDFISH_PASSWORD`, read only), `WALL_METER=ipmi:local` (the server's management controller, read on the machine), or a smart plug (`tools/wall_meter.py` lists them). Omni-Compass never reads it.

48.1.13 Before any machine: the simulated card

`python3 tools/gpu_physics_sim.py --out results/gpu/sim/after` runs Omni's own GPU governor, with its current settings, against a modelled card for 10 paired repetitions in about two minutes. No GPU is needed. Every number it prints comes from the card model, not from a meter, so it is a preview of what the governor does and never the result. `results/gpu/sim/before` holds the same run with the settings before the share floor and busy gate were added.

48.1.14 What you will get

A table from the GPU's own power meter:

- native against Omni watching only, and native against Omni governing;
- the preregistered primary result: work per energy, in requests served per kilojoule, with its 95% interval.

It ends with one verdict line, chosen by rule (`tools/gpu_reps.py`, `label`), one of:

- **SUPERIOR WITHIN GUARDRAILS**: more requests per kJ (GAIN, clear of the noise) with every service guardrail held;
- **ENERGY IMPROVEMENT WITH SERVICE TRADEOFF**: more requests per kJ, clear of the noise, with a service guardrail failed;
- **AWAY FROM ITS AIM**: fewer requests per kJ, clear of the noise;
- **NONINFERIOR / INCONCLUSIVE** or **NOT ESTABLISHED**: no difference beyond the noise, with the guardrails held or not;
- **NOT ATTRIBUTABLE: WATCH DIFFERS FROM NATIVE**, or **INVALID**.

Whatever it says is the answer, and it is the first number in this project that Omni-Compass's own code did not compute.

48.2 The GPU on Lambda: setting it up, click by click

This connects GitHub to a Lambda Cloud account so one button, the `lambda-gpu` workflow, can rent one GPU machine, run the GPU test on it at the exact commit the button is pressed on (`scripts/gpu_8card.sh` on eight cards, or `scripts/gpu_rented_run.sh` on one), bring every result file back as the run's artifact, and give the machine back. The GPU runs start from the branch `gpu-omni-v26` (the engine that stands, made at omni-v26's push and levelled with main at every landing; the run's page prints the exact commit). The design is `docs/GPU_PREREGISTRATION.md`; what each stage measures is `docs/GPU_RUN_GUIDE.md`, sections C and D.

About ten minutes, once. Lambda bills the card on file from the moment a machine starts until it is given back; nothing here starts a machine until a dry run has shown the price and the run is started again with `dry_run` set to `no`.

48.2.1 A Lambda account with a card

1. On the laptop, open **cloud.lambda.ai** and click **Sign up** (or **Log in**).
2. Add a card under **Settings**, **Billing**. Lambda rents no machine to an account without one.

48.2.2 The two keys, made in Lambda

The API key (it lets GitHub rent and give back a machine):

1. In Lambda's menu on the left, click **API keys**, then **Generate API key**. Name it `omni-github`.
2. Lambda shows the key once. Leave that page open for step 3.

The SSH key (it lets GitHub log in to the machine it rented):

1. In the menu on the left, click **SSH keys**, then **Add SSH key**, then **Generate a new key**.
2. Name it `omni-key`. Lambda downloads a file, **omni-key.pem**, to the laptop's **Downloads** folder. That file is the private half; Lambda keeps the public half under the name `omni-key`.

Never copy either key from a screen by selecting it: a long block is cut short when it is selected (on 18 October the Google key was stored cut short that way, and every Google set failed at the login). Use the copy button for the API key and the downloaded file for the SSH key.

48.2.3 Put the three secrets in GitHub

1. Open the repository on GitHub, click **Settings** (the repository's tab, at the top right), then on the left **Secrets and variables**, then **Actions**.
2. **New repository secret**. Name: `LAMBDA_API_KEY`. Secret: the API key from step 2. **Add secret**.
3. On the laptop, open **Downloads**, right-click **omni-key.pem**, **Open with**, **Notepad** (on a Mac: **TextEdit**). Press **Ctrl+A** (select all), then **Ctrl+C** (copy): the whole file, from `-----BEGIN` to `PRIVATE KEY-----`.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

4. **New repository secret**. Name: `LAMBDA_SSH_PRIVATE_KEY`. Secret: click in the box, **Ctrl+V**. **Add secret**.
5. **New repository secret**. Name: `LAMBDA_SSH_KEY_NAME`. Secret: `omni-key` (exactly the name given in step 2). **Add secret**.

Keep **omni-key.pem** in a safe folder on the laptop (it also lets you log in to a rented machine yourself) and never send it to anyone. These three are passwords for this one purpose: never paste them anywhere but GitHub.

48.2.4 The dry run (free)

1. On GitHub, **Actions**, then **lambda-gpu** on the left, then **Run workflow** (on the right).
2. Branch: **gpu-omni-v26**. `test`: `1card`. `mode`: `fast`. Leave `dry_run` at **yes**. Click **Run workflow**.
3. In about a minute the run's page shows, at no cost:
   - the SSH key check: "SSH key omni-key: Lambda holds it, and the stored private key is its other half";
   - the price an hour, the regions with a machine free now, and the estimate for the hour budget plus one hour;
   - "Dry run: the secrets and the key pair are ready; nothing rented."

A red run says which of the three secrets to fix (a missing secret, a key name Lambda does not hold, a private key that is not the other half of `omni-key`), and nothing is rented. "No machine of this type is free in any region now" is Lambda's stock at that moment: try again later, or name another `region` or `instance_type`.

48.2.5 The real runs

The same button with `dry_run` set to **no**. The `max_cost` box (400 by default) is a ceiling in US dollars for the hour budget plus one hour: above it nothing is rented.

`test` `mode`	What runs	Hour budget (given back by)	At Lambda's list price
`1card` `fast`	the compute counted run on one A10	8 h (9 h)	one A10 $1.29 an hour on 24 October: about $12
`1card` `stacks`	the whole stacks with the card inside: the wire check and smoke, then the seven organisms at 1, 10 and 100 copies, native and Omni-Compass, the preregistered 5, 3 and 2 repetitions by size (`hil_profile` `standard`)	32 h (33 h)	about $43 a run at most; A, B and C (`tag`) each rent their own A10 and run side by side

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

`test` `mode`	What runs	Hour budget (given back by)	At Lambda's list price
`1card` `stacks-full`	the same stacks with the card fully loaded inside them (`docs/GPU_PREREGISTRATION.md`, amendment 16): more requests offered than the card serves, so the work done inside the same rented time can rise	32 h (33 h)	about $43 a run at most; A, B and C side by side
`8card` `pooled` (default)	every stage on eight A100 cards, repetitions pooled across the cards	10.5 h (11.5 h)	$22.32 an hour on 1 November (the price the launch printed; it was $14.32 earlier): about $257 at most
`8card` `fast`	a short look, never the result to show	4 h (5 h)	about $112 at most
`1card` `full`	the whole one-card test	32 h (33 h)	about $43
`8card` `full`	the whole design on eight cards	26 h (27 h)	about $603 at most (over the button's default $400 ceiling: raise `max_cost` to run it)

The price the dry run prints is Lambda's own at that moment; the table is an example. The one-card and the eight-card tests may run at the same time (one run of each at once; a second press of the same test waits for the first, unless its `tag`, A, B or C, differs: each tag is its own machine).

The machine is given back when the run prints its last line, or at the hour budget plus one hour whatever happens, or at the end of the workflow if anything before it failed. Each give-back is acknowledged by Lambda; if Lambda does not acknowledge it, the run turns red and says so. Then, by hand: **cloud.lambda.ai**, **Instances**, tick the machine (its name starts `omni-`), **Terminate**.

A run cancelled by hand keeps watching its machine (the watch jobs run on through a cancel, so a give-back is never lost), and a run whose test stopped early is given back at once by the watch since 24 October. For a machine still left billing under an older run: **Actions**, **lambda-gpu**, **Run workflow**, **test** `giveback`, **give_back** `omni-1card-` (or `omni-8card-`, or the machine's whole name). It gives back every machine whose name starts so, rents nothing, and never touches a machine launched by hand on Lambda's page; the stuck run then sees its machine gone and ends, and the next run of that test starts.

48.2.6 Afterwards

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The results are the run's artifacts (`lambda-gpu-watch*-<run id>`); the founder hears what they say before anything goes up. To remove GitHub's access: in Lambda, **API keys**, delete `omni-github`, and **SSH keys**, delete `omni-key`; then delete the three secrets in GitHub.

PART SIX

Operating It

The OFF switch, the rules the governor obeys, the log it keeps, and the care of a running installation.

CHAPTER 49

The OFF Switch, the Rules, and the Log

The rules Omni-Compass keeps on your system.

1. **The master switch, for the whole harness, in a human hand:** `python3 tools/omni_switch.py off` turns every Omni-Compass governor on the machine off at once (the Kubernetes controller and the GPU governors). Each puts every setting it ever wrote back to the value it read before its first write, reads it back and exits; the command waits until all have, and says so. While the switch is OFF, no governor will start. `python3 tools/omni_switch.py on` allows them to be started again (nothing restarts by itself); `status` shows the switch and every governor running. Use it the moment anything looks wrong, including a suspected breach. Each governor also keeps its own switch for one muscle at a time: the kill file (or `OMNI_KILL=1`, or SIGTERM to the GPU governor). **If a governor dies without handing back** (killed outright, the machine crashed, it hung), nothing it wrote is left in place: every governor records, before its first write, the exact commands that put every setting back, and renews a lease every decision. Run `python3 tools/omni_switch.py watchdog` as its own service next to the governors: it hands back for any governor whose process is gone or whose lease has run out (a hung one is stopped first). `status` names any governor that died without handing back. The watchdog acts only on records its own user wrote that no other user can change (run it as the governors' user, or name theirs with `--trust-uid`), and never signals a process number the system has given to another process. Put the switch and the registry in a directory only the governors' user can write (`OMNI_MASTER_OFF`, `OMNI_REGISTRY`); `status` warns when they are not.
2. It records before it acts (annotations on Kubernetes objects; the `snapshot` line in the GPU audit).
3. It watches before it writes.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

4. It never acts blind.
5. Service first: while response time is over its target, and for `--slo-clear-s` seconds after (180 by default), nothing is given back.
6. Every change is read back; no new order goes on top of one that has not landed.
7. The living band and the cover: no organ is driven outside its range; machines are parked, never switched off by Omni-Compass; it never evicts or moves a pod.
8. One writer: if anyone else changes a knob, Omni-Compass stops writing it and leaves it alone.
9. Everything is logged: every read, decision, write and reason goes to the audit log.

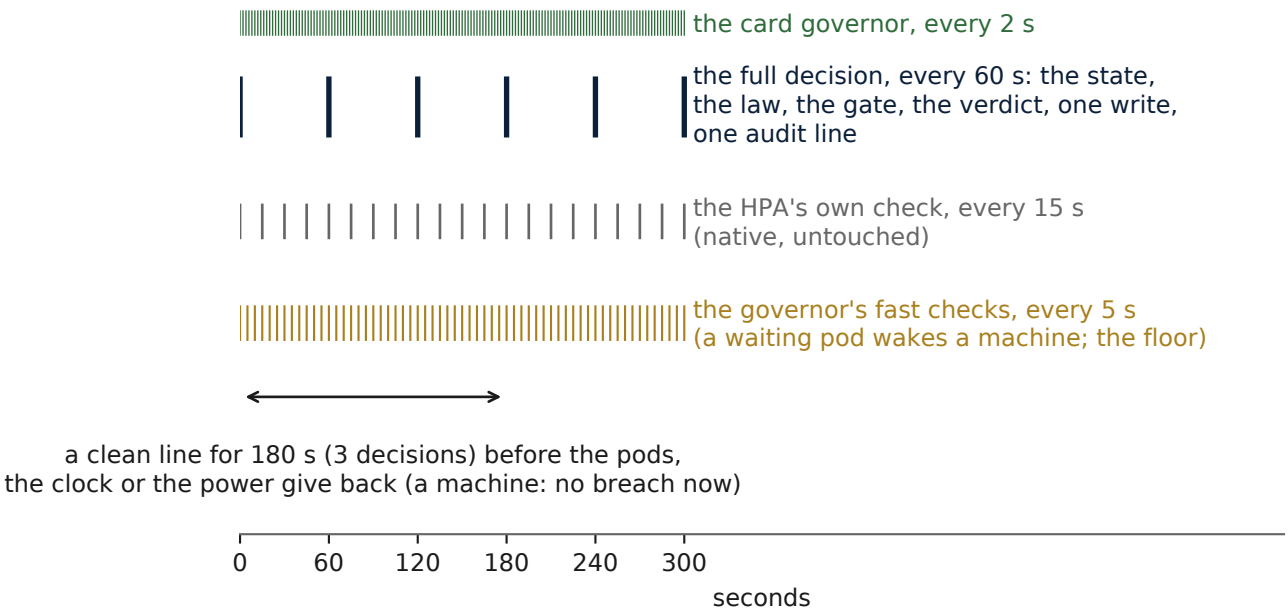

Figure 49. Timing diagram: the governor's clocks against the native controllers' own, over five minutes. The card governor decides every 2 s; the Kubernetes governor's fast checks run every 5 s (a waiting pod wakes a machine; the floor); native's own autoscaler keeps its 15-second check underneath, untouched; the full decision (the state, the law, the gate, the verdict, one write, one audit line) runs every 15 s, and nothing is given back until the line has been clean for 180 s, twelve decisions.

On autopilot: why nobody babysits it. Omni-Compass is an autopilot: a closed-loop supervisory controller that runs, steers and corrects itself inside the system it governs, as a self-driving car's controller does inside the car. Once the paired trial on a muscle has passed and Omni-Compass is set to write, nobody turns a knob and nobody has to react. Every change is Omni-Compass's own, and it audits itself: every write is read back from the system, every machine it gives back is kept only after its own paired trial shows the response time holds, every reading, decision and reason is in its audit, and it hands every setting back at the end; nobody has to check its work either. It holds the response time at the centre of its band, under the line, and acts as the reading approaches the line, so the correction lands before the line is crossed, not after a person is paged. What a native stack pays in people for the same service (an engineer watching dashboards, paged while the service is

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

over its line, retuning an autoscaler's target or a node pool by hand) is the **babysitting tax**, and every Kubernetes and cloud receipt counts it in both arms: the **alert minutes** (whole minutes whose 95th percentile, failed requests counted over, was over the line: the minutes an on-call page would be open; judged, the aim lower), the **settings commands the governor wrote on its own**, and the **share of its additions decided while the service was still inside its line** (both shown, not judged). No person touches either arm of a paired run. The aim in the cloud is **no alert minute at all**: a minute over the line is a person woken, so an alert minute in the omni arm is a LOSS of the aim, its cause found and fixed and the test run again. Where native itself is short of machines (over its line on its own), the receipt says so beside the row: the same machines can be made to carry more, but no governor creates compute that the machines do not have.

The three ways a governor stops, and what each leaves behind. A referee or an underwriter should know exactly what happens to a governed system in each of the three ways Omni-Compass can stop, because the answer is the same in all three: every setting at native, read back, with no record left.

- **The reset** (every setting handed back to native) is the planned end of a run. The governor sees its reset file, hands every setting back in reverse order of power-up, reads each back, writes its last audit line and exits 0. Every benchmark arm ends with one and then checks the cluster from outside the governor: the HPA target at the operator's, the replica range as set, every pod's CPU limit at its shipped value, every worker back in service, no `omnicompass.io/` annotation left on any object. An arm whose reset check fails is invalid and is left out of the table, never counted.
- **The kill switch** (security) is the unplanned end of trust. `tools/omni_switch.py off` writes the switch file and sends every registered governor SIGTERM; each performs the same hand-back as a reset and exits; the command waits until all have and reports any that have not. No governor starts while the switch is off. It is one switch for the whole machine, not one per muscle, because the case it exists for, something driving a system through Omni-Compass's brain, is not a case for picking which muscle to stop.
- **A death without a hand-back** (killed outright, a crash, a hang) is the case the lease covers. Before its first write every governor registers itself with the exact command that puts every setting back (`omni_controller.controller --restore-only`, which restores from the snapshot annotations on the objects themselves, so it needs no memory of the dead process), and renews a lease every decision. The watchdog (`tools/omni_switch.py watchdog`), run as its own service beside Omni-Compass's processes, finds any of them that is gone or whose lease is older than its limit (five decision periods, at least two minutes), stops a hung one, runs its recorded restore command, and records what it did. The robustness benchmark (Chapter 60, in preparation) kills the governor outright in the middle of a governed run and measures how many seconds pass before every setting is back and what the service saw in that gap.

Reading the log.

Line	Meaning
`gate: a sense is blind`	a reading failed; nothing is given back until it returns

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

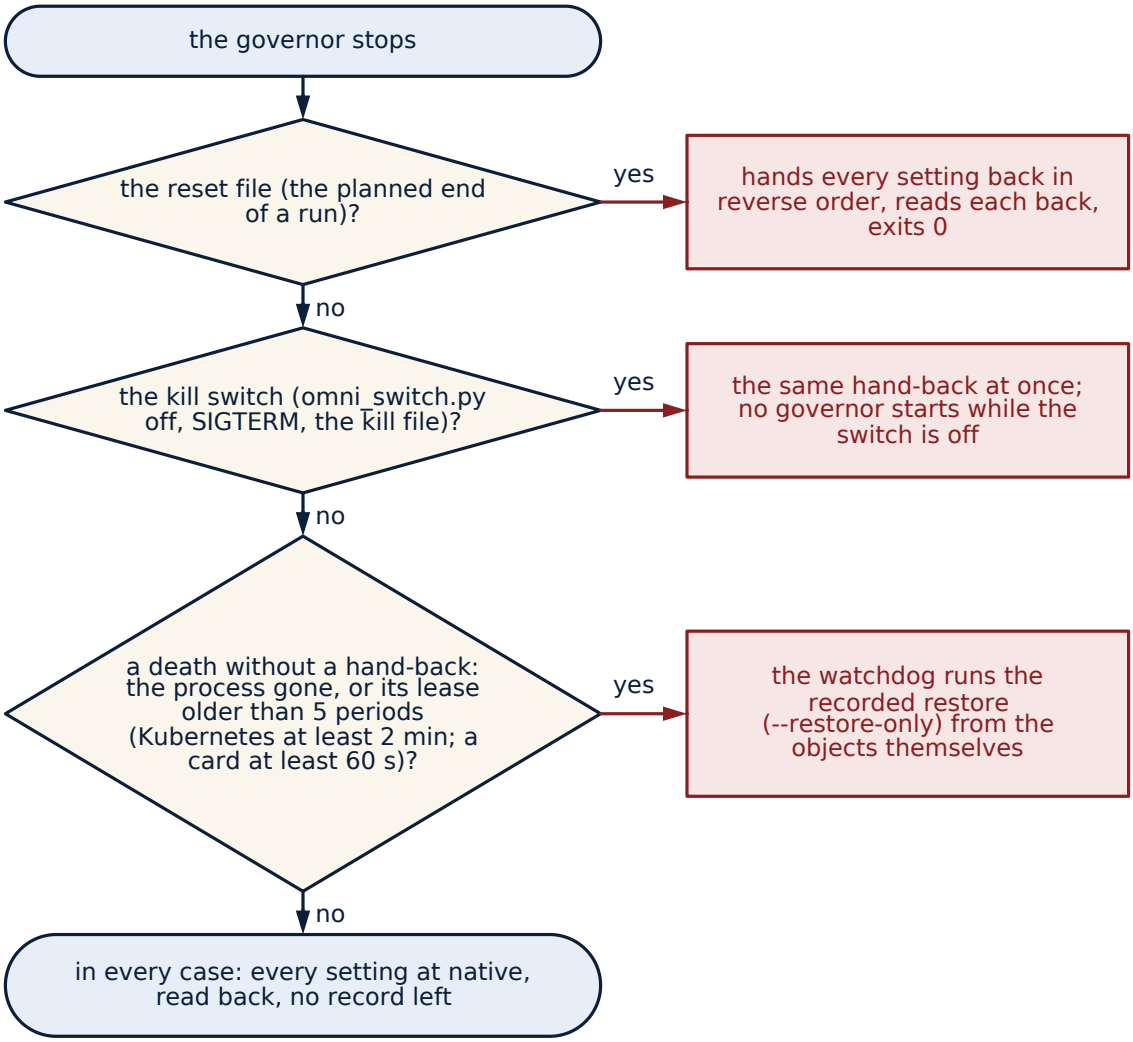

Figure 50. Flowchart: the three ways a governor stops. The reset file at the planned end of a run hands every setting back in reverse order, reads each back and exits 0; the kill switch (omni_switch.py off, SIGTERM or the kill file) does the same at once, and no governor starts while the switch is off; a death without a hand-back (the process gone, or its lease older than five periods) is caught by the watchdog, which runs the recorded restore from the objects themselves. In every case every setting ends at native, read back, with no record left.

Line	Meaning
`gate: pods scaling up`	pods first, machines after
`decision failed (n in a row)`	the cluster could not be reached; nothing was written; turn it OFF for native
`decided_by: compass`	the compass set the wires this decision
`decided_by: fail_up` / `blind_fail_up`	the service crossed the 0.95 wall, or a sense went blind: full capacity at once

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

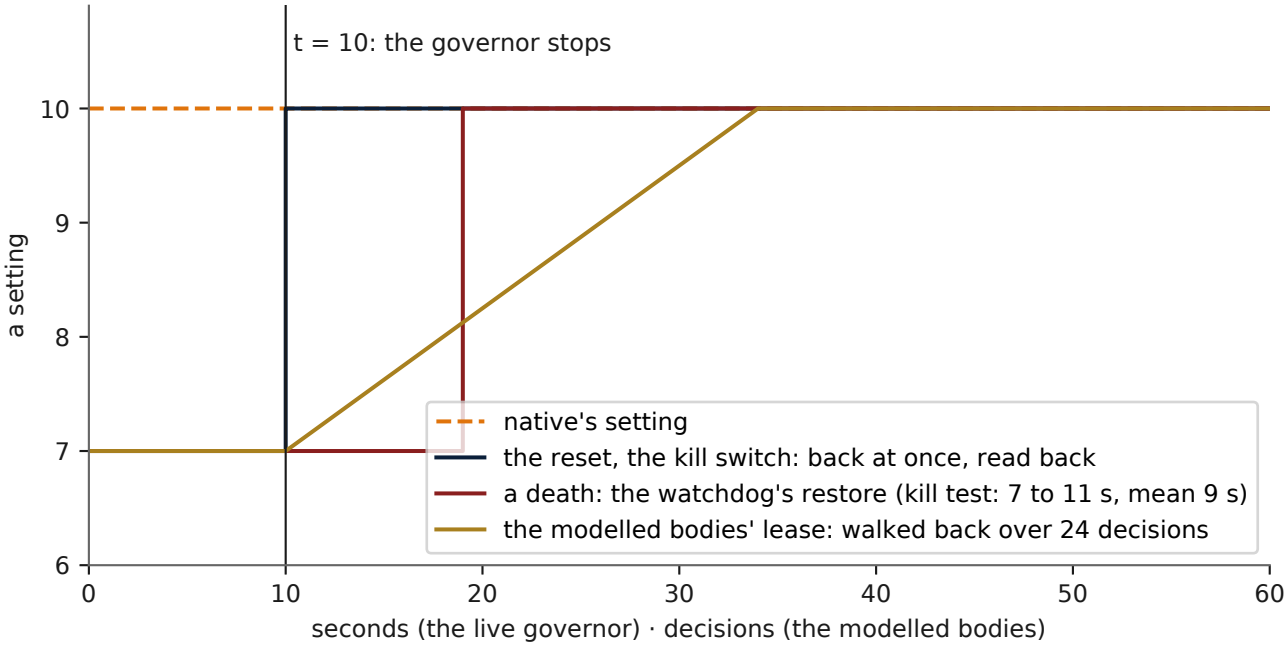

Figure 51. Timing diagram: the hand-back after a reset, a kill and a death. At t = 10 the governor stops. A reset or the kill switch writes every setting back at once and reads it back; a death without a hand-back is caught by the watchdog, which restored within 7 to 11 s (mean 9 s) in the kill test; in the modelled bodies the lease walks the setting back to native over 24 decisions.

Line	Meaning
`decided_by: thermal_hold`	the card reported a heat slowdown; nothing was tightened
`foreign_writer`	someone else changed a knob; Omni-Compass now observes only
`restored ... ok: true`	the OFF switch put every setting back and read it back
`"watchdog": "handed back"` (in the watchdog's own log)	a governor died or hung without handing back; the watchdog ran its recorded restore command; `ok` says whether every command exited 0
`cruise: on` / `cruise: off`	work waited for a place for two decisions: machines in service up to the pool's own top; the line has been empty for two: cruise ends
`idle_floor`	the work is done and demand is at zero: the pedal lifted all the way, straight to the floor in one move
`verdict_state: left native`	no step of the slow knob passed the paired trial: the knob is never moved on this muscle

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Line	Meaning
`shield_interventions`	the shield clipped a write to its bounds or its step limit; the count says how often
`overhead` (the last line of the audit)	the governor's own CPU over the window: its process and every command it ran

How to read an audit from end to end. The audit (`audit.jsonl`, one JSON record a line, every line timestamped) is the governor's complete account of itself, and a reader can follow a run through it without the manual: the first lines are the snapshot (every setting as found, written to the objects as annotations so a watchdog can restore from them); then, every decision, the readings (the response time and its age, the pods waiting, the machines seen, whether any sense is blind), the compass's position and force (`compass`), the authority the nervous system granted and the release gate's reason (`authority`, `node_gate`), the decision itself (the machines recommended against the machines seen, the HPA target set), every write with the command that made it and the value read back, and the decision's wall time (`decision_ms`); in cruise, the floor step's silence; at the end, the reset's writes and read-backs and the `overhead` record. The benchmark harness prints a decision trail from the audit at the end of every omni arm (`scripts/kind_bench.sh`), one line a decision, so a reviewer reading a run's log sees what the governor saw and did at each minute.

CHAPTER 50

Maintenance, Upgrades and Security

- Run `python3 verify.py` after every upgrade; it must end `VERIFICATION: PASS`.
- Upgrade in watch mode first; take the levels again from level 1.

What an upgrade is, and what it is not. The engine is frozen and fingerprinted (Chapter 59). An upgrade that changes any engine file, a rule, a gain, a guard, a preset or a muscle, is by definition the next engine version, and every published result is run again on it before it is quoted beside the old ones; `tools/omni_version.py` says which version a checkout carries, and a checkout that matches none says which files differ. An upgrade that changes only the harness, the tools, the tables or this manual leaves the engine's fingerprint as it was and every result standing; the robustness harness of section 60.15 is an example, built without touching an engine file. An operator can therefore tell, from one command, whether a new checkout is the engine the results were made on or something that must prove itself again.

- The container runs non-root, read-only, with no capabilities; the Kubernetes identity has only the permissions of the level you run.
- The GPU governor needs root only for `nvidia-smi -pl` and `-lgc`.
- Report a security issue as `SECURITY.md` describes.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

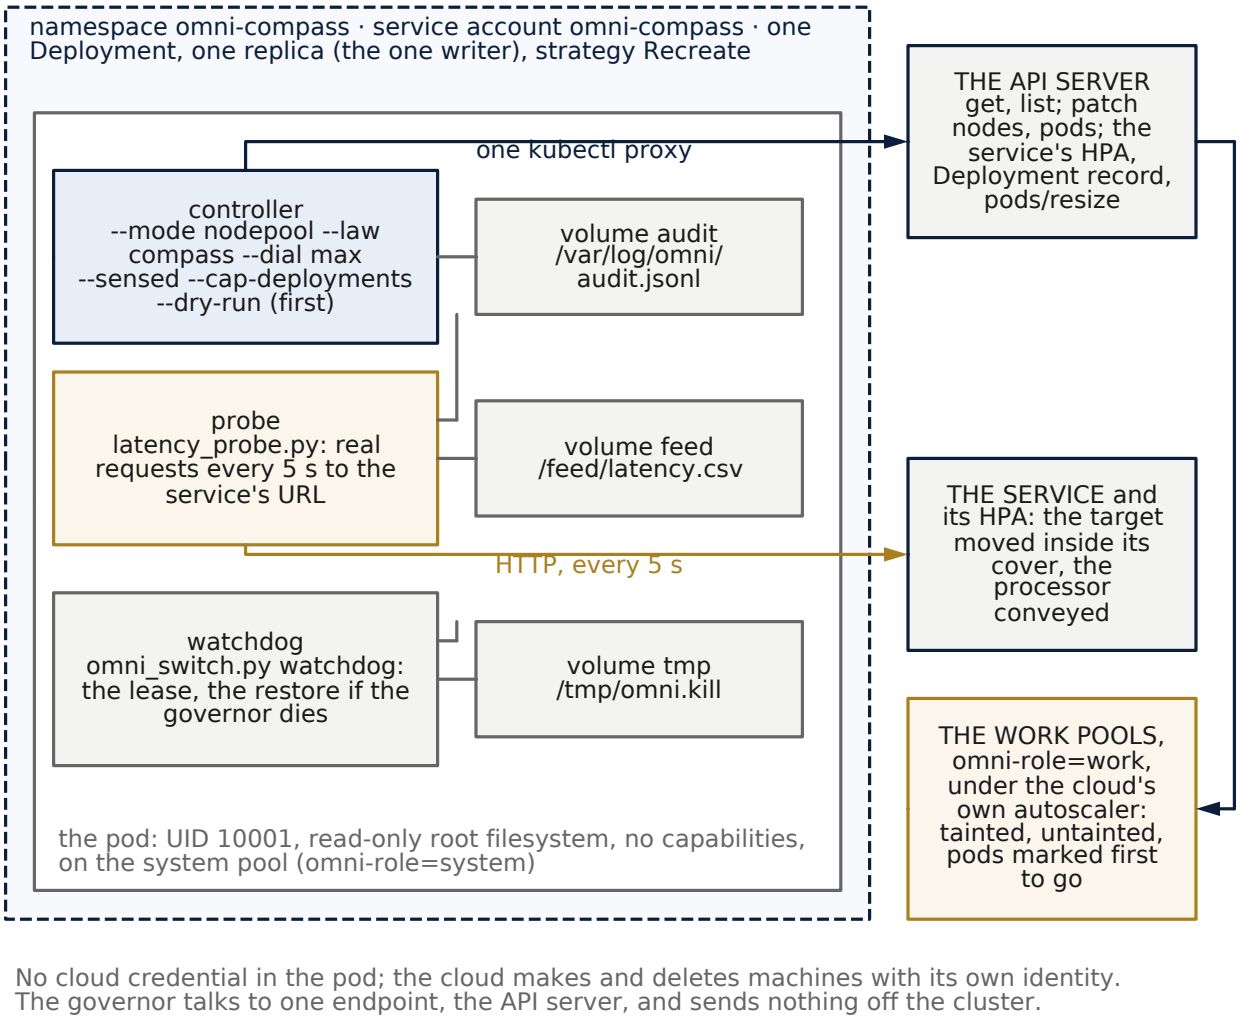

Figure 52. Deployment diagram: the governor on a managed cluster. One namespace, one service account, one Deployment of one replica (the one writer): the controller container with its command line, the probe beside it writing the feed to a shared volume, and the watchdog holding the lease; the audit, the feed and the kill file each on their own volume.

Outside the pod: the API server, reached through one kubectl proxy and granted get, list, patch nodes and patch pods, nothing else; the service and its autoscaler, untouched in the cloud mode; and the work pools under the cloud's own autoscaler, where machines are tainted, untainted and their pods marked first to go. No cloud credential is in the pod.

Least privilege, proven on every run. The Kubernetes governor runs as its own service account (`deploy/kind/rbac-omni.yaml`) with exactly the verbs the level needs: patch on the governed HPA, nodes, pods and the governed deployment, get on its security ConfigMap, create on pod evictions. It cannot delete nodes, create or delete pods or deployments, touch the load generator or anything in `kube-system`, read any secret, create a namespace, or write its own security hold. Every benchmark arm records `kubectl auth can-i` for each of these and fails if a "cannot" reads yes or a "can" reads no

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(`bench-*/rbac_omni.txt` in every archived run). The security hold itself is a ConfigMap another identity owns: when its key reads `hold: "true"` every expansion is blocked, and the governor cannot clear it.

What never leaves the repository. Cloud credentials live only in the repository's encrypted secrets and are used only by the workflows that need them; no credential, key or token appears in any file, log, table or commit, and the founder is never asked for one in conversation. The repository carries SPDX license identifiers on every source file so that license scanners (Black Duck, FOSSA, Snyk) read the evaluation license correctly, and every generated report carries the legal notice at its head and foot (`tools/legal.py`). Patent, copyright and trademark filings are referred to as filed; no filing number appears anywhere.

Supply chain. Everything the benchmarks download is pinned and checked: metrics-server by version and SHA-256 (`scripts/kind_bench.sh`), Apache Kafka against the Apache Software Foundation's own SHA-512 file for that release, Redis as the Ubuntu runner's own package, MongoDB from its publisher's own repository signed by the publisher's key and YCSB against the SHA-256 written in its preregistration, gym-pybullet-drones at one named commit, Python packages by `requirements.txt`. A download whose checksum does not match stops the run before anything else happens.

The upgrade drill, step by step. An operator who receives a new checkout does five things, in order, and stops at the first that fails. First, `python3 tools/omni_version.py`: if it prints the version the operator's results were made on, the engine is unchanged and the rest of the drill is about the harness; if it prints a list of differing files, the checkout is a new engine and nothing the operator measured before applies to it until measured again. Second, `python3 verify.py`, which must end with its pass line; the verifier runs every unit test, the shield's adversarial cases, the Python-against-C++ agreement and the release manifest, and a checkout that fails it is not installed anywhere. Third, the wire check on the operator's own stack, which proves that every wire the new checkout would use still follows, reads back and returns. Fourth, watch mode for at least one full cycle of the operator's load, reading the log the governor would have written and comparing its would-be decisions against what the operator would have done. Fifth, the levels again from level one, each with its paired receipt. An upgrade that skips a step has not been upgraded; it has been installed.

The security hold, and who holds it. The hold is the one control that outranks the governor's own judgment, and it is deliberately not the governor's to hold. It lives in a ConfigMap owned by another identity (the operator's security team, in practice); while its key reads true, every expansion the governor would make is blocked and every contraction is still allowed, so a governor under a hold can only give capacity back, never take more. The governor reads the hold on every decision and records in its audit that it read it; it has no verb that could write it. The kill switch (Chapter 49) is the blunter instrument beside it: the hold constrains a running Omni-Compass, the switch stops every Omni-Compass process on the machine and hands everything back. An operator who suspects anything untoward uses the switch first, reads the audit second, and rotates the governor's identity third; the hold is for the slower case of a change window or an incident elsewhere during which no one wants capacity added.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

What has been reviewed, and what has not. Reviewed and tested on every run: the governor's permissions against the list above, read from the cluster itself; the shield's refusal of every write past a cover, of every give-back while blind, and of every move under a hold, on two million generated cases; the lease and the watchdog's hand-back on a real cluster, thirty times (section 60.8); the checksums of every download. Not yet done, and said so: an independent security review of the code by a party outside the company, which is in the open program (section 60.15), and a penetration test of the deployed governor on a customer-like cluster. Until those are done, the operator's own review stands in for them, and this section tells the operator exactly what to look at.

CHAPTER 51

The Operator Manual

Before you wire anything: read `DISCLOSURES.md`. Omni-Compass acts only through the wires it is given; it cannot be slapped on. If your paired receipts differ from the published benchmarks in direction, the first presumption is wiring: check the installation with section 42.5 of the manual (*Wired right or wired wrong*).

The current manual is `docs/INTEGRATION_MANUAL.md` (every stack, every level, every switch). This page is kept for its first-person account of the laws; where the two differ, the integration manual is current.

I am Omni-Compass. I am the brain and the nervous system; your stack is the muscle. Everything below is what I am and what I do, in my own terms and in my own mathematics. Every command and flag here exists in this repository.

51.1 My face

My face is the compass. It is not decoration: it is how I read myself, every decision, and it is written into my code (`omnicompass/compass.py`).

51.1.1 The wheel

My deviation E, over its ceiling E[max], runs along the horizontal. Its rate of change runs along the vertical. Where I stand on that wheel is my heading, measured clockwise from north:

Point	Letter	Heading	Where I am
+	A	0°	rising through rest

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Point	Letter	Heading	Where I am
⇄	Δ	45°	expansion: above rest and rising, exchange under way
>	B	90°	peak extension: the turn, where my metric flips (k → −k)
⊤	Λ	135°	dispersion: above rest and easing, my ceiling holds
−	Ω	180°	falling through rest
≈	Π	225°	compression: below rest, settling into my basin
<	Γ	270°	deepest compression: the turn at my floor
✦	Ψ	315°	re-alignment: below rest and rising, ignition ahead

My rim carries twenty-four letters, fifteen degrees apart, clockwise from A:

A E Z Δ H Θ B I K Λ M N Ω Ξ O Π P Σ Γ T Y Ψ Φ X

Every reading names its letter.

51.1.2 The four strokes

My quadrants are the strokes of the closed circle:

Quadrant	Stroke	Where I am
I	Expansion	above rest, rising
II	Dispersion	above rest, easing
III	Compression	below rest, falling
IV	Re-alignment	below rest, rising

The wheel turns I → II → III → IV → I:

- **Ignition:** crossing from IV into I.
- **Metric flip:** the turn at peak extension.
- **Continuity:** I am continuous through every crossing:

$\lim X(t^{-}) = \lim X(t^{+})$

Nothing in me switches off, and nothing restarts.

- **Counting:** I count every circle I close.

51.1.3 The axle

My axle is the structural basin S. Its rest point S* solves my equation (6):

$\delta - \alpha_s S - \tfrac{3}{4} \beta_s S^2 = 0$

Without the axle, deviation diverges. With it, deviation circulates.

All patents, copyrights and trademarks filed in the USA.

51.1.4 Closing the circle

I hold the three conditions of the Unified Circle Principle and report them every decision:

- **$\dot{X} = G(X)$, $X(0) \in \Omega$.** Ω is my living band: every level I hand out lies between 5% and 95% of its range.
- **$G(X) \cdot n(X) \leq 0$ on $\partial\Omega$.** At a boundary, my next move points inward, never outward.
- **$\nabla L(X) \cdot G(X) \leq 0$.** My ledger $L = E^2/2 + \Phi(S) - \Phi(S^*)$ descends when nothing forces me. When outside load forces me, I say so; I never hide it.
- **$\Rightarrow \lim X(t) \in M^*$.** I settle into my basin.

A reading, as I print it on every decision trail:

```
Ψ ✦ 318.2° Re-alignment: re-alignment, ignition ahead | Ω: machine_fil
    ↪ l below the floor, returning | G·n≤0 yes | L 0.4121 -0.0133 | ax
    ↪ le S 0.19 (rest 1.90) | circles 3
```

51.2 My laws in your system

51.2.1 One switch, for all of me, in a human hand

I have one switch, the Unified Control Switch. A human turns it; I never turn it myself.

- **ON:** I am the primary control authority inside the scope you granted me.
- **OFF:** every setting I changed returns to what it was, and your native control takes full custody.

```
# OFF (all of me, at once, at any moment, for any reason, including a
    ↪ suspicion that someone has taken my brain):
kubectl -n omni-compass exec deploy/omni-compass -- touch /tmp/omni.ki
    ↪ ll
# ON:
kubectl -n omni-compass exec deploy/omni-compass -- rm /tmp/omni.kill
```

What OFF restores. Every HPA CPU target and replica range, pod CPU limit, idle mark, paused rollout or job, GPU and CPU frequency ceiling, and containment quota. Each restore is recorded, and each lever restores on its own.

What never trips the switch.

- The switch never turns one organ off.
- No boundary, no error and no failed decision trips it.
- A decision that fails writes nothing, and my next decision comes on time.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

51.2.2 My living band: 5% to 95%

Every level I hand out lives inside Ω = [0.05, 0.95] of its range:

- frequency ceilings, GPU power limits and the site power envelope;
- each organ's share of the energy budget;
- how full I run any machine.

No part of the body is driven to zero: a part with no work idles at its floor, alive and ready. No part is driven to its absolute top: I never spend the last five percent.

Tested over 300,000 of my states and 60,000 of my energy allocations (`tests/test_living_band.py`).

51.2.3 Machines idle; I never switch them off, and I never move a pod

When I need fewer machines, I idle the rest by letting their work leave on its own:

1. **Prefer not:** the machine is marked `omnicompass.io/idle:PreferNoSchedule`. New pods go to the open machines first, but a pod that finds them full lands here at once, so no pod ever waits because of me.
2. **Marked:** its pods are marked first to go (`controller.kubernetes.io/pod-deletion-cost`), the machine with the least work first. When the load falls, your autoscaler's own scale-down removes exactly those pods, emptying one machine at a time.
3. **Idle:** once its work is gone, the machine stays powered and Ready, gauged down to its idle floor.

While it still carries work, a machine counts as in service at full power. No pod is ever evicted, moved or restarted to idle a machine. When work returns, I remove the mark, the warm machines still carrying work first; it is in service at once, with no boot and no power cycling.

An idle machine draws `park_frac × idle power` (0.25), never zero.

51.2.4 Every change is continuous

- I idle at most one machine per decision.
- I wake a machine within five seconds of a pod waiting for a place.
- My pod reflex reads the queue every five seconds.

Nothing jumps, and nothing is restarted.

51.2.5 My pod sense: the muscle makes the pods

Your autoscaler is the muscle that makes and removes pods. I never start or stop a pod it would not.

Its rule is replicas = current × busy ÷ target. I read the same rule from the live queue every five seconds:

- a replica serving requests answers in R = S / (1 − u), so u = 1 − S/R;

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- S is the bare service time: the fastest tenth of the recent requests;
- R is the recent mean response, over the same window;
- your target, in queue terms, is target × request ÷ limit.

I record what the queue needs (`pod_reflex_reading`) and act only through the energy I give the pods and the target I hold for the muscle.

The target I hold. g is the CPU each pod is guaranteed with your autoscaler's largest count spread over the machines in service, divided by your limit. That target moves only when a machine idles or wakes, never each time a pod starts or leaves.

The muscle's own clock. I hold each target for your autoscaler's scale-down window (300 s unless you set one), the time it takes to answer a target. A target moved faster would pull the muscle mid-movement and start pods it then removes. A response-time breach returns your own target at once.

The reflex that raises the floor itself exists (`--pod-reflex-writes`); it is off unless you turn it on.

51.2.6 My energy is moved, never created

One budget comes in, and I convey it across the body by need (`omnicompass/conveyance.py`):

- $da_i/dt = \kappa\, a_i\, (e_i - \bar{e})$;
- the budget is conserved exactly, and each organ converges to its share of the demand;
- organs with no work idle at their floor, and what they do not need goes where it is needed;
- nothing leaves Ω.

On each machine, I hand its idle CPU to the pods serving on it:

$$c_i = \min\left(\max\left(L_i,\ (0.95\, A_j - Q_j) / |P_j|\right),\ 0.95\, A_j \right)$$

- A_j is the machine's CPU.
- Q_j is what every other pod on it has requested.
- P_j is its serving pods.
- L_i is the limit you gave the pod.

A pod's CPU limit is a quota. A request that needs more than one quota period waits for the next one while the machine stands idle. That wait is energy withheld from the work, not saved, because the request spends the same CPU-seconds either way.

I change the limit in place: the pod is not restarted, its request is untouched, and it never gets less than you gave it. Every fifteen seconds a new pod gets its share. The OFF switch returns every pod to your limit.

51.2.7 I see before I act

My nervous system runs both ways:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Afferent:** a sense that is stale, frozen or unreadable is blind, and while any sense is blind I give nothing back.
- **Efferent:** I read back every order I give. An order that did not land blocks my next release.

51.3 Wiring me in, step by step

Take the steps in order. Take the next step only when this step's pass condition holds. The switch works at every step.

51.3.1 Step 0. What your stack needs

1. Kubernetes 1.34 or newer, with metrics-server (`kubectl top nodes` answers).
2. An HPA with a CPU target on each service I govern.
3. A PodDisruptionBudget on each service, for your own maintenance; I never evict a pod.
4. A readiness probe and a short preStop pause on each service, so a new pod never takes traffic before it answers and a pod your autoscaler removes never drops a request as it leaves (`deploy/kind/demo.yaml`).
5. A response-time feed for each governed service, as CSV `elapsed_seconds,latency_ms,ok`. `scripts/latency_probe.py` writes one.

51.3.2 Step 1. Build me

```
docker build -f deploy/Dockerfile -t <registry>/omni-compass:<tag> .
docker push <registry>/omni-compass:<tag>
```

I run as non-root, with a read-only root filesystem and no Linux capabilities. I carry my engine, my nervous system, my compass and my frozen law.

51.3.3 Step 2. Let me watch (monitor only)

```
kubectl apply -f deploy/install/omni-compass.yaml     # set the image
    ↪ line; --mode observe
kubectl -n omni-compass logs deploy/omni-compass -f
```

Identity. I hold a read-only identity. `scripts/pilot_shadow.sh` records `kubectl auth can-i` receipts showing I cannot write.

Pass condition. Zero writes, and readings your operators agree with.

51.3.4 Step 3. Give me the pods (on top of your autoscalers)

1. Grant `patch horizontalpodautoscalers` and `patch pods/resize` (`deploy/rbac-target.yaml`, `deploy/kind/rbac-omni.yaml`).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

2. Run me with `--mode target --latency-file <feed> --slo-ms <your p95 target>`.

Your HPAs keep scaling. My pod reflex raises floors ahead of the CPU averages.

Targets. I hold your promise in queue terms: busy = target × request ÷ limit.

- g is the CPU each pod is guaranteed (section II.5), divided by your limit; the target that keeps each pod exactly as busy is g times yours.
- The pod answers faster, because it has g times the CPU, at the same busy share.
- Apart from that, I only tighten, never loosen.
- While response time is over your target, and for 180 s after (the clear time), your own target stands.

Pass condition. p95, p99 and failed requests never behind native.

51.3.5 Step 4. Give me the machines

1. Grant `patch nodes` and `patch pods` for the first-to-go mark (`deploy/kind/rbac-omni.yaml`).
2. Run me with `--mode nodepool --active-nodes-only --closure /app/law/closure.json --node-scale-cmd "<park/wake command with {n}>"`.

Your platform	The park/wake command
any cluster, kind, bare metal	`bash scripts/kind_nodepool.sh {n}` (close to new work and mark first to go; open again, warm machines first)
Karpenter / EKS Auto Mode	the NodePool CPU limit at `{n} × node CPU`, parked nodes kept, not consolidated away
Cluster Autoscaler node group	the group's desired size, with scale-down through parking, not deletion
OpenShift	the worker MachineSet replicas, parked, not deleted

I give a machine back only when all of these hold:

- every sense is live;
- my last order landed;
- pods are not scaling up;
- nothing is waiting for a place;
- the machines that remain stay inside Ω.

Pass condition. Fewer machines in service and less energy, with no LOSS on any service gauge.

51.3.6 Step 5. Let me decide alone (Kubernetes as the muscle only)

Add `--strict-replicas`:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- I decide each service's replica floor and when to shrink;
- your HPA stays as the fast up-reflex;
- my node law sizes the machines.

Pass condition. As step 4.

51.3.7 Step 6. Give me the hardware

Organ	How to wire it
CPU frequency	`--cpufreq-policy-root /sys/devices/system/cpu/cpufreq --cpufreq-require-schedutil --rapl-cmd "<prints package watts>"`
GPU	`--gpu-query-cmd "nvidia-smi --query-gpu=power.draw,temperature.gpu --format=csv,noheader,nounits" --gpu-power-cmd "nvidia-smi -pl {w}" --gpu-max-w <max>`
Power and cooling	`--power-cmd "<prints site watts>" --site-limit-w <limit> --cooling-cmd "<sets {c}>"`
Batch and rollouts	`--batch --batch-pace --rollout-guard <ns/deployment>`

Pass condition. Energy per unit of work down, with no LOSS on any service gauge.

51.3.8 Step 7. The switch drill, at every step

1. Turn me OFF.
2. Check every setting is back to its recorded original, and no `omnicompass.io/*` annotation remains.
3. Turn me ON.

`scripts/kind_bench.sh` does exactly this after every live run.

51.4 How to see me work

- **Live, paired, on real Kubernetes:** `benchmark-reps.yml` (a commit with `[reps]`, or by hand). Each repetition runs native, me on top, and me alone, back to back on one machine.
- **On your own machine:** `bash RUN_LIVE.sh 3`.
- **Every run leaves:**
  - my audit log of every read, write and compass reading;
  - my decision trail;
  - my identity receipts;

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- a SHA-256 fingerprint of every file.

51.5 When you read these lines

I say	I mean
`gate: a sense is blind`	I cannot see, so I give nothing back until I can
`gate: pods scaling up`	pods first, machines after
`decision failed (n in a row)`	I could not reach the cluster and wrote nothing; turn me OFF if you want native now
`pod_reflex_reading`	what the queue needs now; the autoscaler decides the pods
`convey: <machine> idle CPU to its k serving pod(s), limit c`	that machine's idle CPU now reaches the work on it
`Ω: machine_fill below the floor, returning`	the machines are underfilled and my move is bringing them back into the band

PART SEVEN

Proving It

Paired runs, receipts, rules written before the runs, and every result to date with its evidence class.

CHAPTER 52

The Receipts, in Their Totality

A **receipt** here is a result file in this repository made by a paired run: the system as it runs on its own (native) and the same system with Omni-Compass on top, the same work in both arms, the rules written down before the counted runs, the engine identified by its fingerprint (`tools/omni_version.py --commit`), every row reported, losses included. A receipt is read in the class of evidence it is: **P** a physical meter, **L** real software (a real Kubernetes cluster, a real database), **S** our own models, **V** a property of the code. S is never presented as proof of a physical saving. A result belongs to the engine it ran on and is never read across engines. Each test is read from its own newest three-run table, and every line below names the engine its runs

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

were on; omni-v25, the engine that stands since 3 November, runs every benchmark again, and its tables replace these as they land (what each version changed: `docs/CHANGE_CONTROL.md`). Every section below is written from its records by `python3 tools/results_chapter.py`, and `verify.py` fails a push where any of it differs from them. How to read a single table: `docs/HOW_TO_READ_THE_RESULTS.md`. The wording of every three-run row: `tools/readings.py`.

52.1 What the receipts say, read together

Every standing below is written from its record by `python3 tools/results_chapter.py`, and `verify.py` fails a push where it differs.

Claim	Standing	Evidence
It sits on top of native and never replaces it	**Shown**	Every live test runs native, and Omni-Compass on top of the same native; the setting is read back at native's value at the end of every arm
It does no harm: never a LOSS against native	**Not shown**: 281 rows read LOSS against its own native on the tables that stand	Each named with its cause and on the next version's list (`docs/LOSS_LEDGER.md`)
More work, faster, on real Kubernetes	**Shown** (L, omni-v26)	All four at once: work inside the response line up 31% to 50% (`results/live/V26_ALL_FOUR.md`); the 95th percentile cut in 9 of 11 Kubernetes tests (`docs/BENEFIT_SHEET.md`)
More work, faster, on databases and caches	**Small** (L, omni-v26)	Redis, the cache's memory ceiling: GAIN, power given, 4.9% LOSS; PostgreSQL, the pooler's pool size: GAIN AND LOSS, 1.8% LOSS; MySQL, the buffer pool's size: GAIN, power given, 12.5% LOSS; MongoDB, the storage engine's cache size: GAIN AND LOSS, 7.1% LOSS; Kafka, the consumer group's size: GAIN, power given, 221.1% GAIN (`docs/BENEFIT_SHEET.md`)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Claim	Standing	Evidence
Fewer machines	**Shown in 2 tests** (L, omni-v26)	a service rightsized by CruiseKube applying its own recommendations, Omni-Compass on top, ten pairs, three runs: machines cut 0.3% to 5.3%, machine-hours cut 0.5% to 5.1%; a queue of jobs: machines cut 13% to 28%, machine-hours cut 13% to 28%, machines after the queue cut 22% to 45%
A smaller cloud bill	**Not shown**	Azure, omni-v18, 97 paired repetitions: the bill up 1.2%, inside the noise, and the work not counted (`results/live/AKS_STEADY_100_OMNI_V18.md`); Google and Amazon wired and not yet run
Less energy for the work, on the chip	**GAIN in all three of our runs** on one card (P, omni-v23)	An A10 fully loaded, its own power meter: energy per served request in runs A, B and C GAIN, 1.79%; GAIN, 1.35%; GAIN, 0.78% (`results/gpu/V23_A10_CAP_FULL_ABC.md`); an A100 on omni-v21: STEADY, under the floor (the three runs' mean 0.12%) (`results/gpu/V21_A100_CAP_ABC.md`); energy at the software end is a declared model (S), never scored
More work for the bill on a GPU	**the runs disagree** (P, omni-v23)	The A10's work for each dollar, its three runs up 1.46%, up 0.73%, down 0.69% (`results/TWO_BILLS.md`)
One governor over every muscle and organism	**Modelled** (S)	1,107 muscles in our own models: 530 GAIN, 577 STEADY, 0 LOSS (`results/realms_v5/REALMS_V5.md`); a few dozen knobs on real systems

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Claim	Standing	Evidence
Its mathematics	**Machine-checked where stated**	24 of 24 theorems proved by SMT and interval arithmetic on the engine as it executes: the compass law, the plug's clip, the verdict, the invariance of E, I and S, the tracking bound inside the basin and the steps to reach it, the bath's stability (`docs/ENGINE_PROOFS.md`); open: CERT-10 for every fixture, convergence of the whole six-state system (`docs/FORMAL_STATUS.md`)

52.2 Receipt by receipt

"In all three" means the same sign in runs A, B and C with every 95% interval clear of zero; STEADY means a change under the 0.5% floor, or no change at all (the key, `tools/readings.py`). Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

52.2.1 Real software and our own models (L and S)

Every test's newest table in one place, written from the same record (`results/BENEFIT_SHEET.json`) by `python3 tools/results_chapter.py`; the gauges behind each reading, in the table's own words, are in `docs/BENEFIT_SHEET.md`.

Test	Class	Engine	Reading	By the index's rule	Table
Every real test together: the Omni index	L	omni-v26	**GAIN AND LOSS**	20.0% GAIN	`results/OMNI_INDEX.md`
Robustness: the two-hour run	L	omni-v26	**GAIN AND LOSS**	6.0% LOSS	`results/live/V26_ROBUST_LONG.md`
Robustness: the governor killed outright mid-run	L	omni-v26	**GAIN AND LOSS**	1.7% LOSS	`results/live/V26_ROBUST_KILL.md`

Test	Class	Engine	Reading	By the index's rule	Table
The big organisms with the real cluster inside, 1,000 copies on Azure	L	omni-v3	**GAIN**	155.0% GAIN	`results/live/V3_BIG_ORGANISM.md`
The 945 modelled muscles as one tower, every muscle written at once	S	omni-v3	**GAIN**	0.3% GAIN	`results/realms/REALMS.md`

52.2.2 Through a cloud (L)

Azure Kubernetes Service, the steady set of 100 paired repetitions on omni-v18: the bill, the machines, the service (`results/live/AKS_STEADY_100_OMNI_V18.md`; run 40069633316, engine omni-v18, 97 paired repetitions read). The record's own reading, carried from it by `python3 tools/results_chapter.py`, its retired word for no difference beyond the noise written as the key's STEADY: the compute bill at list price up 1.2% by the mean of the 97 pairs, its 95% interval across zero (−$0.0007 to +$0.0021 a repetition): power given, not beyond the noise; machines billed up 1.2%, the same; the response time's 99th percentile GAIN (down 11.0%, its interval clear of zero); every other service gauge STEADY or not beyond the noise; failed requests up 3.9% by the mean, its interval across zero. The stopping rule read the bill at every look and never decided it, so the set ran to the paid cap of 100.

52.2.3 A physical meter (P)

Every three-run table of a card's own meter (class P) in `results/gpu/`, written from the tables by `python3 tools/results_chapter.py`, newest engine first: the headline gauges in the table's own words, then how all its rows read by the one key; every row stands in the table. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

- **The organisms on the eight-card machine: six organisms, each on its own A100, three runs on rented machines** (`results/gpu/V23_A100_8CARD_STACKS_ABC.md`, omni-v23): 225 rows, the stacks (our own models, class S): 36 shown, not judged, 24 other; the card (its own meter, class P): 63 shown, not judged, 42 other; both together: 36 shown, not judged, 24 other.
- **The card on omni-v23, the power cap at 70% of the card's top (cap): three runs on an A10** (`results/gpu/V23_A10_CAP_ABC.md`, omni-v23): energy per served request (J) STEADY, under the floor (the three runs' mean 0.38%); requests served STEADY, the same; response time, 95th percentile (ms) the runs disagree. Its 13 gauges: 3 GAIN, 7 STEADY, 3 the runs disagree.
- **The card on omni-v23, the power cap at 70% of the card's top, the full load (cap-full): three runs on an A10** (`results/gpu/V23_A10_CAP_FULL_ABC.md`, omni-v23): energy per served request (J) GAIN in all three of our runs; requests served the runs disagree; response time, 95th percentile (ms) the runs disagree. Its 13 gauges: 7 GAIN, 1 STEADY, 5 the runs disagree.

All patents, copyrights and trademarks filed in the USA.

- **The card's compute run on omni-v23: an A10 at the usual load, the firmware alone against Omni-Compass on top, three runs on rented cards** (`results/gpu/V23_A10_FAST_ABC.md`, omni-v23): energy per served request (J) STEADY, under the floor (the three runs' mean 0.13%); requests served STEADY, the same; response time, 95th percentile (ms) the runs disagree. Its 13 gauges: 12 STEADY, 1 the runs disagree.
- **The organisms on the card, fully loaded: the seven organisms with an A10 inside, the card offered 1.3 times its full-power capacity, three runs on rented cards** (`results/gpu/V23_A10_STACKS_FULL_ABC.md`, omni-v23): 300 rows, the stacks (our own models, class S): 56 STEADY, 24 shown, not judged; the card (its own meter, class P): 1 GAIN, 6 power given, 84 STEADY, 7 LOSS, 42 shown, not judged; both together: 56 STEADY, 24 shown, not judged.
- **The card on omni-v21, the power cap at 70% of the card's top (cap): three runs on an A100** (`results/gpu/V21_A100_CAP_ABC.md`, omni-v21): energy per served request (J) STEADY, under the floor (the three runs' mean 0.12%); requests served STEADY, the same; response time, 95th percentile (ms) the runs disagree. Its 13 gauges: 2 GAIN, 8 STEADY, 2 LOSS, 1 the runs disagree.
- **The card on omni-v21, the power cap at 70% of the card's top (cap-full): three runs on an A100** (`results/gpu/V21_A100_CAP_FULL_ABC.md`, omni-v21): energy per served request (J) STEADY, under the floor (the three runs' mean 0.07%); requests served STEADY, under the floor (the three runs' mean 0.15%); response time, 95th percentile (ms) LOSS by the mean of our three runs, beyond the noise in 0 of 3. Its 13 gauges: 1 GAIN, 10 STEADY, 2 LOSS.
- **The card on omni-v21, the tune-down (dial save): three runs on an A100** (`results/gpu/V21_A100_SAVE_ABC.md`, omni-v21): energy per served request (J) GAIN by the mean of our three runs, beyond the noise in 1 of 3; requests served STEADY, the same; response time, 95th percentile (ms) STEADY, under the floor (the three runs' mean 0.04%). Its 13 gauges: 6 GAIN, 6 STEADY, 1 the runs disagree.
- **The stacked box on omni-v21: the seven organisms with an A10 inside, three runs on rented cards** (`results/gpu/V21_STACKS_A10_ABC.md`, omni-v21): 260 rows, the stacks (our own models, class S): 56 STEADY, 24 shown, not judged; the card (its own meter, class P): 1 GAIN, 2 power given, 63 STEADY, 3 LOSS, 1 the runs disagree, 30 shown, not judged; both together: 56 STEADY, 24 shown, not judged.

52.2.4 The code (V)

The max's guarantees, one by one, with the code path that makes each one true: `docs/FORMAL_V5.md`. The theorems proved by SMT and interval arithmetic on the engine as it executes: `docs/ENGINE_PROOFS.md`, and what is still open: `docs/FORMAL_STATUS.md`. The safety shield's four properties (no invariant violated, idempotent, no invented action, minimal intervention) are checked over 100,000 random and adversarial cases on every push and 1,000,000 in a full check (`verify.py`), and held over 2,000,000 when the test was run on its own on 3 November 2026 (`python3 tests/test_shield_properties.py`: 0 violations); the C++ twins are checked against the Python on every push (`verify.py`).

All patents, copyrights and trademarks filed in the USA.

52.2.5 The archive itself

Every archived run carries `SHA256SUMS_ALL.txt`, the SHA-256 of every file in its folder. A sum is a fingerprint: it shows that a file has not changed since the sum was written, not who wrote it. From 31 October 2026 the archive job signs each run's sums with Sigstore, keyless, under GitHub's own identity for that job, and the signature is entered in Sigstore's public transparency log (`SHA256SUMS_ALL.txt.sigstore.json` beside the sums). `python3 tools/verify_receipt.py <run folder>` checks every file against its sum and the sums against their signature; a run archived before that day reads "sums only". `python3 tools/reproduce.py` rebuilds every table from the archived runs. Neither check is an outside review: they show that the files and the tables have not changed, not that an outside party has repeated the runs (`docs/PILOT_PROTOCOL.md` is how that is done).

52.3 What would change these readings

- On the chip, the card's energy for each request served reads GAIN in all three runs on one A10 at the power cap's full load (omni-v23) and STEADY on the other card runs above; a run on other cards that showed no difference at the same work would confine that reading to the card and load it ran on.
- An A, B or C run that disagrees with the others turns a row into "the runs disagree"; it is looked into, never dropped.
- A loss in all three runs is reported as it stands, its cause looked for in our own wiring, setup and scoring first, and the next set run on the fix.

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

CHAPTER 53

How to Read the Results

53.1 The key: GAIN, STEADY and LOSS

Every judged reading in Omni-Compass is one of three words: **GAIN**, **STEADY** or **LOSS**. Better, same and worse are not used anywhere. The word is decided by what the gauge is for, never by the plus or minus sign of its number: who sets the aim differs from one system to the next, and each gauge's aim is written in its preregistration before the runs.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Word	What each letter stands for	Its sense in underwriting	What it means in a table
GAIN	**G** Growth (asset appreciation); **A** Advantage (risk reduction); **I** Improvement (margin expansion); **N** Net-positive (profitable outcome)	surplus and positive variance	the gauge moved toward its declared aim against native: more work done, a shorter wait, fewer misses or failures, or a resource cut
STEADY	**S** Stable (zero variance); **T** True to baseline (expected norm); **E** Equilibrium (balanced risk); **A** At par (no net change); **D** Drift-free (within the 0.5% floor); **Y** Yield held (nothing lost)	the par baseline: equilibrium	native and Omni-Compass within 0.5% of each other: the mean of the three runs' changes under the 0.5% floor, or no change at all; a knob native already runs at the top of its range is STEADY, at its limit on native
LOSS	**L** Leakage (capital drain); **O** Off-track (adverse selection); **S** Setback (claim liability); **S** Subpar (negative variance)	actuarial deficit and exposure	the gauge moved away from its declared aim: less work done, a longer wait, more misses or failures

How the sign of a number becomes a word:

- **Time waited, missed or failed** (a response time, time over the line, failed requests): a fall is GAIN, a rise is LOSS.
- **Work done** (work inside the line, throughput, a hit rate): a rise is GAIN, a fall is LOSS.
- **A resource spent or held** (energy, the power drawn and its peaks and swings, machines, memory, processor time, a bill, wear on a part): a fall is a **cut**, and a cut is GAIN. A rise is **power given**: what Omni put in to buy the work and the speed shown beside it. Power given is always shown and never hidden, and it is never called a loss (the founder's order of 12 October 2026: the max rides every muscle's edge; it never shaves). A peak is power held, so a peak that rose is power given, in a data centre and in a building alike (17 October).
- **Work bought with each unit of a resource** (work per energy): a rise is a cut in what each unit of work took, a GAIN; a fall is power given, because it falls when more power is given for the same work.
- So a minus can read GAIN (a response time cut 65%, a bill cut 30%) and a plus can read LOSS (failed requests up).
- **The floor, and every change above it** (the founder's orders of 20 and 24 October 2026): a change of half of one percent (0.5%) or more either way is a change, and reads **GAIN** or **LOSS** (or **power given**) by what the gauge is for; STEADY is kept for a change under 0.5%. The change is the mean of the three runs' changes, each in percent of native. Where every run moved the same way with its 95% interval clear of zero, the word reads **in all three of our runs**; otherwise it reads **by the mean of our three runs** and

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

says in how many of the three runs it stood beyond the noise, so a reader sees how firmly it stands. Where runs moved 0.5% or more in opposite directions, the reading is **the runs disagree**. A mean under 0.5% reads **STEADY, under the floor**, with its size.

- **Two numbers, never mixed** (the referee's work order of 25 October): every row shows native's value and Omni-Compass's, the **raw change** (Omni-Compass − native) / native with its true sign, + for a rise and − for a fall whatever the gauge is for, labelled raw, and apart from it the word with its size and no sign. A bill cut 3% reads raw −3.0%, GAIN 3.0%; failed requests up 2% read raw +2.0%, LOSS 2.0%; a pod start wait from 0.22 s to 0.83 s reads raw +275.0%, LOSS 275.0%; a change under the 0.5% floor reads STEADY 0.3%. No raw sign is ever turned to match a word.

Some preregistrations name their outcome with a label written before the runs (for example SUPERIOR WITHIN GUARDRAILS in the card protocol). The label stays as it was frozen, and every table shows it with its word first: TOWARD ITS AIMS reads GAIN; BOTH WAYS reads GAIN AND LOSS; AWAY FROM ITS AIMS reads LOSS; SAME AS NATIVE reads STEADY (the same as native); AT ITS LIMIT ON NATIVE reads STEADY (at its limit on native); SUPERIOR WITHIN GUARDRAILS reads GAIN (within the guardrails); ENERGY IMPROVEMENT WITH SERVICE TRADEOFF reads GAIN AND LOSS (energy cut, service traded for it); SERVICE IMPROVEMENT WITH ENERGY TRADEOFF reads GAIN, power given (service GAIN, energy given for it); NONINFERIOR / INCONCLUSIVE reads STEADY (inside the noise, within the guardrails); NOT ESTABLISHED reads STEADY (not established: inside the noise, a guardrail crossed on the mean). A run that breaks its own validity checks reads INVALID and carries no word.

Every reading is one of these. **GAIN, LOSS or power given in all three of our runs**: A, B and C moved the same way, every 95% interval clear of zero. **GAIN, LOSS or power given by the mean of our three runs**: the runs' mean moved 0.5% or more, with the count of runs that stood beyond the noise beside it. **STEADY, under the floor**: the mean moved less than 0.5%. **STEADY, the same**: no change at all. **The runs disagree**: runs moved 0.5% or more in opposite directions, so the test is unstable there and is looked into. **Shown, not judged**: a gauge declared in advance as shown only, such as the knob's own setting.

Why these three words: they are the words of underwriting and actuarial work, where every outcome is graded as surplus, par or deficit, and each letter spells out the same rule. Omni-Compass is there to add (GAIN), never to take (LOSS), and to hand a muscle back to its own native setting where it cannot add (STEADY). Its first rule is do no harm, in the founder's meaning of 19 October 2026: the organism Omni-Compass governs is never left turning out less than its native controllers make it turn out, nor less healthy, and every muscle works only as far as its own limit (`DISCLOSURES.md`, section 3). So **LOSS should never appear**: where it does, the row stays in the table, its cause is found and fixed (our own wiring first, then native's setup, then the scoring) and the test is run again.

Disclosure and disclaimer: GAIN, STEADY and LOSS, and the letters behind them, are Dubra Software Inc. / The Omni-Compass LLC's own convention for reading its own results. The underwriting senses explain the words; they are not an actuarial, financial or insurance opinion, and no outside body defined, reviewed or approved them. A reading states what our own runs measured against native under the declared aims, not a promise about any other system; every number stands beside its word, so a reader can judge it by any other

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

convention. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

53.2 Where Omni-Compass sits, and what each benchmark shows

Omni-Compass is software. It always sits on top of a native controller. A system runs it in one of two places, on bare metal or through the cloud, and in each place there are two arms, native and Omni-Compass on top of native: four arms, each read by its bill and the work done inside it. These are the words for them, used the same way on every page.

Place	Its benchmark	What it must show	Its readings
The software end	Kubernetes and the data stores on GitHub's machines (kind), class L	the benefit, by the one key, and that it holds	`docs/BENEFIT_SHEET.md`, `results/OMNI_INDEX.md`
Bare metal, the chip	a graphics card on Lambda run directly, its rental the bill and its own power meter beside it, class P	that it holds, and the work done inside its bill, A against B: the work per dollar and per joule	`results/TWO_BILLS.md`, `results/gpu/`
Through the cloud	Kubernetes through Azure's AKS, the machines it bills, class L	that it holds, and the work done inside its bill, C against D: the work per dollar	`results/TWO_BILLS.md` and each set's `results/live/AKS_*.md`
The whole organism	the places composed by the product law, class S of P and L	how the places add up, an explanation and never a measurement	`results/WHOLE_SYSTEM.md`

- **The software end.** The programs that carry the work: Kubernetes with its pod and cluster autoscalers, its schedulers and the orchestrators on it, the data stores (PostgreSQL, MySQL, Redis, MongoDB, Kafka) and the services they serve. Omni-Compass sits on top of their native controllers. This is where its benefit lives and where it is measured: real software on real computers (class L), on GitHub's own machines in kind clusters. Those machines are rented runners, never called bare metal and never called the chip.
- **Bare metal.** The first of the two places a system runs (the founder's order of 1 November 2026): the owner's own machines, or a chip run directly, with the chip's own controllers under the software. Its bill is the machine's own: the hours it runs, and the energy the chip's own meter reads. The software end goes with Omni-Compass to it, and there Omni-Compass can reach the chip's own knobs too.
- **Through the cloud.** The same software end on a cloud provider's rented machines: Kubernetes through the cloud (Azure's AKS today; Google's GKE and Amazon's EKS wired the same way, not yet run), the machines billed by the hour at list price and added or removed by the cloud's own autoscaler. Its bill is the cloud's own; the cloud's chips and back end are inside its price and out of Omni-Compass's reach: it

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

governs what the cloud gives, through the cloud's own Kubernetes. The cloud is the wire between the software end and the provider's bare metal. The wire makes no benefit of its own, and no tenant can meter the provider's chips.

- **The chip.** Bare metal's own part: the processor or graphics card under the software, with its own controllers (the power limit, the clocks, the heat), measured with the card's own power meter (class P) where Omni-Compass sets the card's knobs through the card's published interface. Omni-Compass built into the silicon, or into a battery's own controller, is not something any run here can test, and it is not claimed.
- **The four arms.** Two places, two arms in each: A, native on bare metal; B, Omni-Compass on top of native on bare metal; C, native through the cloud; D, Omni-Compass on top of native through the cloud. Each is read by its bill and the work done inside it, each place on its own, since a system runs in one or the other; an owner who runs work in both may weigh them only by its own spend, through G(total) (`results/TWO_BILLS.md`, `docs/WORK_PER_BILL.md`). The software end's tests are one set read three ways (the Omni index on work, speed and machines; the same on work and speed alone; the layers composed): they never add together, and none of them is either place's bill.
- **Hold.** Omni-Compass on top of native harms nothing in that place: every judged gauge (the work done, the response time, the minutes over the line, the pods waiting, the failures) reads STEADY or GAIN against native by the one key, and a resource that rose (the bill, the machine-hours, the energy) is read beside it as power given. A place holds when its runs read no LOSS.
- **Where the benefit lives.** At the software end, where it is made and measured, with no bill in it. It shows through on the two bills, native against Omni-Compass on native: on bare metal the work done inside the machine's own bill (each dollar, and each joule of the chip's own meter), and through the cloud the work done inside the cloud's own bill (each dollar). The chip and the wire themselves add no gain of their own: they are where Omni-Compass must hold. A benchmark that holds is the proof of no harm in its place; the benefit is shown where it lives and explained for the rest.
- **Work for the bill.** The one number every receipt is read for: the work done for each dollar of the bill, $E = W / B$ (written once in `results/TWO_BILLS.md`), in each place native against Omni-Compass on native, $G = E(\text{Omni-Compass on native}) / E(\text{native}) - 1 = (1 + \Delta W) / (1 + \Delta B) - 1 \approx \Delta W - \Delta B$, ΔW the change in the work done and ΔB the change in the bill. A bill that rises is power given; there is more work for the bill when the work rises more than the bill ($\Delta W > \Delta B$, $G > 0$). Both arms pay the same prices, so a place's price level cancels in its G. A system that runs in one place reads that place's G alone; an owner who runs work in both weighs them by its own native spend $S(p)$, $G(\text{total}) = \Sigma_p S(p)(1 + \Delta W(p)) / \Sigma_p S(p)(1 + \Delta B(p)) - 1$ (`docs/WORK_PER_BILL.md`).
- **One mechanism, in one place, felt along the whole path.** Omni-Compass acts in one place, the software end, on top of the controllers a stack already runs; it changes nothing in the chip and nothing in the network or the cloud. Its effect travels the whole path the work travels: a request starts in the software, crosses the wire (the owner's own racks or a cloud's machines), is computed on the chip and comes back. So the effect is checked at every place: the software end shows the gain (more work, faster, the machines

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

it took read beside it, a rise power given), and the wire and the chip are read for whether it holds and carry the gain to their bills. Two places are tested because a system runs in only those two; one mechanism makes the gain, the way a city's traffic signals make more trips an hour on the same roads and the same cars.

This chapter teaches you to read every table Omni-Compass produces. You do not need to know Kubernetes or GPUs to follow it. Read the five ideas first, then go to the table you have in front of you.

53.3 The five ideas behind every table

1. **Native, Omni-Compass on native, and Omni-Compass direct.** Every result compares a system running alone ("native": Kubernetes alone, the card's own firmware alone, a building's own controller alone) with the same system with Omni-Compass sitting on top of it (Omni-Compass on native, "omni" in the tables), and, since the founder's order of 23 October, wherever native's own controller can be switched off, with the same system run by Omni-Compass alone (Omni-Compass direct, "solo" or "Omni direct" in the records). Same machine, same work, same moment: the only difference is Omni-Compass, and which controller moves the knob. The three arms are always shown together, and each pair is read on its own.
2. **Paired runs.** Each comparison is run many times ("repetitions" or "runs"), each time with both arms on the same seed (the same pattern of work). Each repetition gives one difference; the table reports the average difference.
3. **The 95% interval.** Next to each average is a range, for example `+0.092% (+0.090 to +0.093)`: the paired mean difference ± $t_{0.975,n-1} \cdot s/\sqrt{n}$, where s is the standard deviation of the n paired differences and $t_{0.975,n-1}$ the two-sided 95% point of Student's t on n − 1 degrees of freedom (`omnicompass/student_t.py`, computed for any n: 4.303 at 3 pairs, 2.262 at 10, 2.093 at 20). The method that draws it covers the true difference in 95 of 100 repetitions of the whole experiment; it is not a 95% chance about this one range.
   - If the whole range is on one side of zero, the difference is **clear of the noise** (a table's "significant" column says "yes"); its word is GAIN, LOSS or power given, by the gauge's aim.
   - If the range includes zero, that run is **not beyond the noise**: it could not tell the arms apart by itself. It does not show that they are equal; how small a difference the run could have seen is the interval's half-width, printed beside it. Since the founder's order of 24 October the word is decided by the size first: a change of 0.5% or more reads its word even where a run's range includes zero ("by the mean of our three runs", with the count of runs beyond the noise), and only a mean under 0.5% reads STEADY (the key above; section "The verdict rules" below).
4. **The word, not the sign.** Every judged reading is GAIN, STEADY or LOSS (the key above). For response time, failures and time over the line a fall is GAIN; for work and work per energy a rise is GAIN; for energy, machines and every other resource spent or held a fall is a cut, a GAIN, and a rise is **power given**, never a loss. Every table gives the word beside the number.
5. **Evidence class.** Every result is marked with how it was measured:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **T**: a theorem;
- **V**: verified in code;
- **S**: our own model (modelled);
- **L**: live software (real Kubernetes);
- **P**: a physical meter (a real card's own power meter).

Only **P** speaks for hardware energy.

53.4 What every result names: the workload, the boundary, the profile, the costs, the requirements and the verdict

The common language of these six is written once in `docs/FACTORY_PROFILE.md`; this section is how to read a result by it. Every result identifies the engine version, the configuration, the hardware or model, the workload and the measurement boundary that produced it, and says nothing beyond them.

The workload contract. Both arms are offered the same work: the same demand at the same moments (an open-loop schedule, the same seeds in every arm), on the same machines, in the same window, against the same service line, all written down before the first counted run in the benchmark's preregistration (`docs/*_PREREGISTRATION.md`). A comparison is valid only for a matched workload; a run whose work was not matched, or a workload left incomplete, is shown as unresolved or invalid and carries no word. The load is a declared input, and a result belongs to the load it names (`DISCLOSURES.md`, section 4).

The measurement boundary. What a result counts, and what it does not: the cluster's machines in service, the host's processor seconds, a card's own meter, the machines a cloud bills, the plant models' energy. Each receipt names its boundary, and nothing outside it is claimed. The energy on GitHub's Kubernetes is a declared formula over machines, not a meter; a model's energy is not a meter's; only class P speaks for hardware energy. The whole organism's composition (`results/WHOLE_SYSTEM.md`) names its three places, the software end, the cloud's wire and the bare metal, and enters a place with no measurement as exactly 1, named.

The profile's identity. Every result names its engine and fingerprint (`python3 tools/omni_version.py`) and the profile that governed it: the **factory profile** (the complete, versioned set of Omni-Compass default settings shipped together; the released one is omni-v19's, the governor's full decision every 60 s with its fast checks every 5 s and every muscle on its card or the engine's setting), a **candidate profile** (a proposed combination under evaluation) or a **custom profile** (an identifiable configuration that differs from the released factory profile, whose results are its own). The **active profile** is the one governing the run in front of you; the live benchmark engine names it with its fingerprint. A matching fingerprint establishes identity; the validation receipts establish what that identified implementation demonstrated. A result is never read across engines, and never across profiles. The best validated factory profile for the declared operating conditions has not yet been established (`docs/FACTORY_PROFILE.md`, section 5): until it is, every published result is the released factory profile's.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The costs. A resource spent or held that fell is a cut, a GAIN; one that rose is **power given**, never a loss. The bill of a deployment route r (on site; through the cloud) is the sum of its costs inside the declared boundary, each counted once, for each arm a (native, Omni-Compass on native, Omni-Compass direct): $C(r, a) = \Sigma_k\ c(r, a, k)$, and its saving is $S(r, a) = (C(r, \text{native}) - C(r, a)) / C(r, \text{native})$, for a positive native cost and a matched workload. A component's percentage (fewer machine-hours, less energy) is a supporting measurement, never the bill. A missing price stays visibly unresolved: today only the cloud's compute is metered in money (Azure, machine-hours at the list price, `results/live/AKS_BILL.md`), so neither route's bill is resolved yet. A whole-workload index (the composition's one number over its gauges) is not a price.

The requirements. Health is the explicit operating requirements: correctness, service limits (the response-time line), resource bounds and every applicable hardware limit; each reading H_j has its limit L_j. A result names which of the two objectives its tune served: the most healthy production, maximise $E[P(\theta)]$ subject to $H_j(\theta) \le L_j$ for every j (the max, the default brain), or the least cost per unit of completed production, minimise $E[C(\theta) / P(\theta)]$ subject to the same requirements (the tune-down, `dial save`, a tune anyone may set; the clouds ran it until 31 October, when the founder struck that rule and every cloud runs the max with the bill judged beside the work). P is the useful output, the work done inside the line. A requirement crossed is read on its own gauge (time over the line, failed requests, alert minutes) and never traded away.

The verdict rules. Every judged gauge is read by the one key (`tools/readings.py`, the key at the top of this page): the word by what the gauge is for, never by its sign; over runs A, B and C the change is the mean of the three runs' changes in percent of native; a mean under 0.5% reads STEADY, under the floor (STEADY, the same where nothing moved); from 0.5% up GAIN, LOSS or power given **in all three of our runs** where every run moved the same way with its 95% interval clear of zero, otherwise **by the mean of our three runs** with the count of runs beyond the noise; runs that moved 0.5% or more in opposite directions read **the runs disagree**; a count that must never rise (failed requests, lost messages) reads LOSS on any rise in any run. Each run's own number wears that run's own word by the same floor. A label written before the run is shown with its word first. A model (class S) is never read as proof of hardware, and a reading on the live tuning bench at any setting other than the factory profile is a variation of the mechanism, never a benchmark result.

53.5 The words in the tables

Word	What it means	Its aim
Work per energy	work done for each unit of energy (requests per kilojoule on a card)	higher
Energy (J, Wh)	the energy used	lower
Work, requests served	how much was done; both arms must serve the same work	equal
Response time, median (p50)	half of the answers were faster than this	lower

Word	What it means	Its aim
Response time, p95	95 of 100 answers were faster than this: the slow answers, what service promises are written on	lower
Response time, p99	99 of 100 answers were faster than this: the slowest answers	lower
Time over the line, violations (pp)	the share of time the service was past its promise, in percentage points	lower
Failed requests, not served	answers that never came	zero
Machines in service, node-hours	how many machines were kept on, and for how long	lower
Band first	the founder's rule: no win unless time over the line is no higher than native's	"held"
Knobs handed back, restored	at the end every setting Omni-Compass touched was put back exactly	True / yes
Label	the verdict, chosen by a rule written before the run, never by hand	see each table

53.6 The GPU card (`results/gpu/run-<stamp>/GPU_REPS.md`)

One card, three arms, many repetitions:

- **native**: the card's firmware alone;
- **watch**: Omni-Compass running and deciding but writing nothing. It must equal native: this proves Omni-Compass watching costs nothing;
- **omni**: Omni-Compass on top, moving the card's clock ceiling and power limit.

Read it in this order:

1. **The verdict line** at the top, one of the labels chosen by rule (`docs/GPU_PREREGISTRATION.md`, amendment 1): SUPERIOR WITHIN GUARDRAILS, ENERGY IMPROVEMENT WITH SERVICE TRADEOFF, NONINFERIOR / INCONCLUSIVE, NOT ESTABLISHED, AWAY FROM ITS AIM, NOT ATTRIBUTABLE or INVALID; each gauge reads GAIN, LOSS or power given **clear of the noise**, or **STEADY, no difference beyond the noise** (amendment 14; the first counted run of 2 October printed "proven" and "not proven" for the same rule).
2. **Work per energy** (requests per kilojoule): the headline. A plus sign with a range wholly above zero is a GAIN clear of the noise.
3. **Requests served** must be equal in every arm. More energy saved by serving less work would be cheating; the bench checks it.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

4. **p95 and p99**: the slow answers. With the verdict rule (`omnicompass/verdict.py`), Omni-Compass never takes a step that makes a request more than 2% slower.
5. **Writes and restore**: how many settings were changed, and that every arm ended at the card's own limit.

The file `omni-gpu-<stamp>-confirmations.tar.gz` holds two such tables: compute-bound work (matrix products) and AI token generation (memory-bound work).

53.7 The card inside the seven organisms (`results/hil/run-<stamp>/HIL.md`)

The real card is wired into each of the seven organisms (the spine, the four realms, the four stacked, the whole tower) at four sizes (1, 10, 100 and 1,000 copies). Each row is one size, one organism and one part:

- **stacks (model)**: the modelled machines (evidence S);
- **card (meter)**: the real card, its own meter (evidence P);
- **both**: the two added together.

The second table lists the card's own receipts for every arm: its energy, requests served, p95, and its power limit at the start and at the end, which must be equal.

53.8 Real Kubernetes (`results/live/LIVE_REPS_<n>.md`)

Each set is 10 paired repetitions on a real Kubernetes cluster (kind): native Kubernetes (its HPA and scheduler) against the same Kubernetes with Omni-Compass on top. Read:

1. **worker nodes in service** and **node-hours**: how many machines were kept busy. A fall is GAIN.
2. **response time p95 and p99**: a fall is GAIN (faster).
3. **failed requests**: must be zero on both sides.
4. **CPU used with Omni's own**: Omni-Compass's own cost included; "no" in the significant column means its cost is inside the noise of the test (the interval beside it gives the size the test could have seen).
5. **The label** at the bottom, by the rule written before the run.

Energy on kind is a declared model, not a meter: kind keeps every machine powered.

53.9 The three-run tables (`results/live/V<engine>_<TEST>.md`, for example `V25_GOLDILOCKS.md`, `V25_CITYLEARN.md`)

Every benchmark since the engine was frozen runs three separate times, A, B and C, on the same bytes, and the table shows all three beside each gauge, each with its own 95% interval. Read the last column first, by the verdict rules above: **GAIN**, **LOSS** or **power given in all three of our runs** (the mean moved 0.5% or more, every run the same way with its interval clear of zero), **by the mean of our three runs** (the mean moved 0.5% or more; the count of runs beyond the noise beside it), **STEADY, under the floor** or **STEADY, the same**, or

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

the runs disagree (runs of 0.5% or more pointing opposite ways: the test is unstable there and is looked into). Every table was read again from its own data by that rule on 24 October (`tools/reread.py`). Nothing reads "confirmed" or "not confirmed": nobody outside Dubra Software Inc. / The Omni-Compass LLC has reviewed or approved these results. The `V<n>_` in a table's name (`V10_`, `V11_`, `V12_` and so on) is the engine the runs carried (`python3 tools/omni_version.py --commit <sha>`); a table never mixes engines, and a reading is never carried from one engine to another. Every LOSS and every power given is in the table beside the GAINs. On the omni-v11 tables there is no LOSS. Power given appears in the grid's dissipated energy in four grids, the tap operations in one, PgBouncer's connections, MySQL's pool from its factory size, Redis's memory and CityLearn's distance from net zero in one district. An earlier engine's LOSS stays in its own table, for example CityLearn's energy not served on omni-v7.

How often the rule reads a difference that is not there. Under no true difference, one run's 95% interval falls wholly above zero with probability 0.025 and wholly below with 0.025. A row reads GAIN or LOSS **in all three of our runs** only when all three independent runs fall on the same side, so its chance of a false reading is $2 \times 0.025^3 \approx 3.1 \times 10^{-5}$. A word read **by the mean of our three runs** carries no such bound: it says the runs' mean moved 0.5% or more, and the count of runs beyond the noise beside it says how firmly; read it with that count. Over a table of 30 judged rows the chance that any one is false is at most $30 \times 3.1 \times 10^{-5} \approx 0.09\%$ (a union bound, as Bonferroni's), and over the 798 judged rows of the omni-v11 tables that carry noise (1,039 judged rows in 23 tables, less the 241 of the deterministic simulators) the expected number of false readings is $798 \times 3.1 \times 10^{-5} \approx 0.02$. The bound assumes the three runs independent; runs on the same kind of machine can share a bias, which three runs cannot remove and the bound does not cover. The price of "in all three of our runs" is power: a small true difference must clear the noise three times, so many rows read by the mean of our three runs are differences too small for a run's pairs to resolve (with 3 pairs a run, $t = 4.303$ and the interval is wide). Every reading is printed with the three intervals behind it. The deterministic simulators (CityLearn, pandapower, MuJoCo) reproduce to the digit, so there the three runs check the harness, not the noise; their STEADY means the same to one part in a million.

53.10 The workload tables (`V<engine>_PGBENCH.md`, `_KAFKA.md`, `_REDIS.md`, `_YCSB.md`, `_SYSBENCH.md`) and the swarm table (`V<engine>_SWARM.md`)

The database, the broker and the cache share one shape. The head names the three runs, their commits and the engine each carried. Then one section per **workload**: the tuning workload first, marked "shown and not counted" because the rules were fitted on it, then the untouched workloads, which are the judged ones. Each section says what the workload is (value sizes, rates, steps) and what native's own capacity measured on that run, so the reader knows how hard native was pushed. The rows are the gauges with their direction in the name: the first row is always **work inside the response line**, the product number; then throughput, the latency percentiles, failures (any increase in any run is marked), **the resource held** (connections, consumers, the memory ceiling: the aim is lower, and Omni-Compass holds more of it wherever it bought a gain, so expect it higher there), the host's CPU (the compass's own cost included), and the knob's moves (shown, not judged). The last line of each section says whether every arm handed the knob back; the last line of the table counts the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

rows toward their aims, away from them and disagreeing across the untouched workloads. The swarm table reads the same way with cells instead of workloads, with collisions voiding a cell, and with a declared reproduction tolerance (one part in a thousand) because PyBullet does not reproduce to the bit across machines; its amendment says so.

53.11 The governor's own cost (`V3_OWN_COST.md`) and the robustness tables (`V<engine>_ROBUST_KILL.md`, `V<engine>_ROBUST_LONG.md`)

`V3_OWN_COST.md` is Omni-Compass's own CPU, from the `overhead` record every omni arm's audit carries, by organism and copies, under the engine each run carried; it is shown and not judged, and it is a few thousandths of one core at every size. The robustness tables (`results/live/V11_ROBUST_KILL.md` and `V11_ROBUST_LONG.md` on the engine that stands; each earlier engine's are its own record) add rows that belong to the omni arm alone, since native has no Omni-Compass process to kill: the seconds from the kill until every setting was back at the operator's (the allowance is 60 s, declared before the run), whether a second Omni-Compass process started and ran to the end, and that process's memory in the last ten minutes over the first ten (a quarter's growth is a leak, declared before the run); the 300 s after the kill (120 s on the tables up to omni-v14's) are compared between the arms like any paired gauge.

53.12 The organisms with a real cluster inside (`SIX_KUBE.md`, `V3_SIX_KUBE.md`, `V3_BIG_ORGANISM.md`)

Two kinds of rows, kept apart: **the cluster** (real Kubernetes, measured) and **the organism** (the modelled stacks around it, evidence S). "Organism behind its window (s)" is shown and not judged; a repetition reads **OFF THE CLOCK** when either arm ended more than 5% of its window late (its last steps saw a cluster whose load had already ended). The pairing stands, the mark stays, and the remedy is a longer window for that size on that machine.

53.13 The one number (`results/OMNI_INDEX.md`)

Every measure is a ratio oriented so that above 1 is a GAIN for Omni-Compass on top of native: work, speed, machines, energy. A test's index is the geometric mean of its ratios, a category's of its tests, the headline of the real categories, each weighted the same. A measure enters only as its three-run reading allows: GAIN, LOSS or power given in all three of our runs enters as the geometric mean of the runs' ratios; anything else (STEADY, the runs disagree, a word read by the mean of our three runs) enters as exactly 1. Modelled muscles are shown beside the index, never inside it.

53.14 The real test, the twenty scenarios and the whole organism

- **The real test** (`results/orchestrator/V18_THREE_ARMS_ABC.md`): one row per pair and gauge, each run's own word beside its number, the three-run reading in bold; below, each arm's totals in each run (requests answered, failed, wrong). The bottom line on the README and the live benchmark

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

engine page reads its pair Omni-Compass on native against native, takes the work row's mean of the three runs as its number and turns its light red on any slower service or failed request. The record's third arm, Omni-Compass alone on the muscles, is not carried there: Omni-Compass is never by itself (the founder's order of 25 October).

- **The twenty scenarios** (`results/scenarios/SCENARIOS_20.md`, class S): ten organisms, each native and with Omni-Compass on native. The first table gives native's own gauges and Omni-Compass on native's word and mean change against native; the sections after it give every run's change with its interval and the reading, each arm's own gauges, the realms runner's contrasts, and every LOSS row by name.
- **The whole organism** (`results/WHOLE_SYSTEM.md`): each layer's ratio oriented so that above 1 is a GAIN, composed by the product law $R(g) = \prod_\ell R_\ell(g)$; read the scope (with or without the card's old run) and the reading (by the index's rule, or every interval carried) before the number. It is a model of measurements, class S of class L and P, and its index is not a price.

53.15 The seven organisms grid (`results/grid_v5/GRID.md`; each engine's runs in `results/grid_v<engine>/`)

Columns are **copies × runs**: 1, 10 and 100 clustered copies, each at 1, 10 and 100 paired runs, and on GitHub's own machines 1,000 of each as well (paid cloud and card runs stop at 100). Rows are the seven organisms: the spine, the four realms, the four stacked and the whole tower. Each square shows the modelled value and the value with the real cluster inside. Read a square as "with Omni-Compass on top, against native, at this many copies, over this many runs". A square still running says so, and one beyond a free runner's memory or time is listed as pending runner capacity, never rented.

53.16 Kubernetes at scale (the `kwok-scale` workflow, its table written by `tools/kwok_report.py` into the run's own files; none is committed to the repository yet)

Real Kubernetes at 50, 500 and 1,000 nodes (KWOK nodes: real Kubernetes objects with no machines behind them):

- **decision time** is how long Omni-Compass takes to decide, at that size;
- **memory** is what it uses;
- **master switch** must read "yes": everything handed back.

53.17 One number, one word (`docs/BENEFIT_SHEET.md`)

In the tables a change keeps its raw sign: a response time that fell reads "-65%", a cache that grew reads "+300%", and the Reading column gives its word, GAIN, STEADY or LOSS, by what the gauge is for (the key above). The benefit sheet turns every gauge the same way round against **its declared aim**: plus is a GAIN,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

minus a LOSS or power given, whatever the gauge measures, and 0% is STEADY. Beside it every change the same in all three of our runs is written out in words, never as a bare sign: "p95 cut 65% (GAIN)", "memory ceiling held up 215% (power given)", so neither can be misread against a table that shows the same changes as "-65%" and "+215%". One number per benchmark, by the index's own rule, with its word beside it. Read that sheet first; read the tables for the rows behind a number, and read their Reading column, never the sign alone. The wiring page uses the same words.

53.18 Wire in, or watch (`docs/WIRING_VERDICTS.md`)

One of three words per knob, by one rule from the tables above. **Write**: a gauge GAIN in all three of our runs and none LOSS or power given in all three of our runs; Omni holds the knob. **Watch**: nothing GAIN in all three of our runs; the knob stays native and Omni only reads it (one wire out, no wire in), and a loss in all three of our runs is named with its cause. **Operator's choice**: gains and losses both the same in all three of our runs, a trade, shown with both readings of the index. Rows marked "shown, not judged" never count. A modelled muscle takes its word from its label: superior is write, a tradeoff label is the operator's choice, the rest is watch. The CSV beside the page (`results/WIRING_VERDICTS.csv`) has one row per knob and per muscle.

53.19 Where to start

1. `docs/STATE_OF_PLAY.md`: one page, every result and how strong it is.
2. `docs/DOSSIER.md`: every result with its chart.
3. This chapter, next to the table in front of you.
4. `DISCLOSURES.md`: what a result is and is not.

53.20 Reading the benefit: more work, or the same work for less

With the work held equal in both arms, the gain from Omni-Compass on top is $G = C[native] / C[omni] - 1$, where C is a resource (machine-hours, CPU core-hours, joules). The same work then needs $1 / (1 + G)$ of the resources, a saving of $G / (1 + G)$: a third more work is a quarter off the bill. The full explanation, the three rules for reading a receipt and where every number stands today are in the Owner's Manual, chapter 3, *Where the Value Comes From* (`docs/OMNI_COMPASS_OWNERS_MANUAL.md`).

CHAPTER 54

The Benefit Sheet: One Number per Benchmark

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

How to read this receipt. Every judged row reads one of three words, decided by what its gauge is for and never by the plus or minus sign of its number. **GAIN**: the gauge moved toward its declared aim against native (more work done, a shorter wait, fewer misses or failures, or a resource cut). **STEADY**: native and Omni-Compass within 0.5% of each other (the mean of the three runs' changes under the 0.5% floor, or no change at all), or the knob is at its limit on native. **LOSS**: the gauge moved away from its aim (less work done, a longer wait, more misses or failures). A resource spent or held (energy, the power drawn and its peaks and swings, machines, memory, processor time, a bill, wear) that fell is a cut, a GAIN; one that rose is **power given**, what Omni-Compass put in to buy the work and the speed shown beside it, always shown and never called a loss; work bought with each unit of a resource (work per energy) that fell is power given too. So a minus can read GAIN (a response time cut) and a plus can read LOSS (failed requests up). A change of 0.5% or more, the mean of the three runs' changes, reads GAIN, LOSS or power given: **in all three of our runs** where A, B and C moved the same way with every interval clear of zero, otherwise **by the mean of our three runs**, with the count of runs beyond the noise beside it; **the runs disagree** names runs that moved 0.5% or more in opposite directions, a test unstable there; **shown, not judged** is a gauge declared shown only. The output follows the input: every reading is the result of the tune, the wiring and the load it names, and where a reading elsewhere differs the first presumption is the wiring (`DISCLOSURES.md`, section 4). The full key, letter by letter: `docs/HOW_TO_READ_THE_RESULTS.md`. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

The founder's orders of 9 and 13 October 2026: next to every benchmark, say whether Omni-Compass on top was a benefit to the system and by how much, in one number whose sign always means the same thing, and say it in **GAIN**, **STEADY** and **LOSS**, judged by what each gauge is for and never by the sign of its number (the key: `docs/HOW_TO_READ_THE_RESULTS.md`). **On this sheet the sign is the system's own declared aims, gauge by gauge: a plus is a GAIN; a minus is a LOSS on work, speed, misses or failures, and power given on a resource spent (energy, machines, memory).** The number carries its word. Beside it every change judged across our three runs is written out with which way it went and its word: "p95 cut 65%

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(GAIN)", "memory ceiling held up 215% (power given)". An operator whose aims differ reads the same numbers the other way.

The result tables (the files in the last column) keep every change with its raw sign: a response time that fell reads "-65%" there, and the Reading column beside it says GAIN.

The four arms (the founder's order of 1 November; `results/TWO_BILLS.md`, `tools/two_bills.py`): **A**, the chip native; **B**, the chip with Omni-Compass on native; **C**, the cloud native; **D**, the cloud with Omni-Compass on native, each read by its bill, the work done inside it and the work per dollar. Every row below is one place's native against Omni-Compass on native (B against A on a chip, D against C through a cloud, the software end's own pairs elsewhere), on the engine it names.

The number is the Omni index's rule (`results/OMNI_INDEX.md`): each judged gauge becomes a ratio oriented so that above one is a GAIN; it counts only where judged across our three runs, anything else counts as exactly one; the number is the geometric mean of the ratios, minus one, in percent. For the tests inside the index the number is the index's own resource reading of that test; for a stack with several workloads it is the stack's index category; for the simulators and the organisms the same arithmetic runs over every judged gauge of their tables. Built from the tables by `tools/benefit_sheet.py`, checked by `verify.py`.

Benefit? reads **GAIN** (gauges GAIN across our three runs, none LOSS or power given), **GAIN, power given** (a GAIN bought with a resource put in, named beside it), **GAIN AND LOSS** (both; the number says which way the trade nets by this scoring, and the wiring page `docs/WIRING_VERDICTS.md` says what pays for what), **LOSS** (a LOSS and no GAIN), **power given** (a resource put in and nothing gained) or **STEADY** (nothing moved 0.5% or more across our three runs). LOSS should never appear: where it does, the row stands and its cause is found and fixed.

Every row names the engine its table ran on (read from the table). Results are never read across engines: a row on an older engine stands as that engine's result until the same benchmark's three runs on the engine that stands replace it here, and every benchmark is rerun on the engine that stands.

54.2 Not on the sheet, and why

- **Azure's managed Kubernetes, the bill** (`results/live/V1_AKS_STEADY.md`, `V1_AKS_BURST.md`): Omni v1, a 4-worker fleet, every gauge STEADY, inside the noise: 0%, and too small a fleet to show one machine.
- **The governor's own share of the machine** (`results/live/V3_OWN_COST.md`): 0.6% to 1.3% of one core at every size; shown, not a benchmark against native.
- **The card (NVIDIA)**: at the factory dial (the max) native already runs both knobs at their top and the governor writes nothing, so the card is not on the sheet; the other tunes, each its own result: The organisms on the eight-card machine: six organisms, each on its own A100, three runs on rented machines: the card's work per energy at 1 copy 4 one repetition in a run: shown, not judged, 2 no value of 6 organisms; at 10 copies 4 one repetition in a run: shown, not judged, 2 no value of 6 organisms; at 100 copies 2 no value, 1 one repetition in a run: shown, not judged of 3 organisms (`results/gpu/V23_A100_8CARD_STACKS_ABC.md`); The card on omni-v23, the power cap at 70% of the card's top (cap): three runs on an A10: work per energy STEADY, under the floor (the three runs' mean 0.38%) (`results/gpu/V23_A10_CAP_ABC.md`); The card on omni-v23, the power cap at 70% of the card's top, the full load (cap-full): three runs on an A10: work per energy GAIN in all three of our runs (`results/gpu/V23_A10_CAP_FULL_ABC.md`); The card's compute run on omni-v23: an A10 at the usual load, the firmware alone against Omni-Compass on top, three runs on rented cards: work per energy STEADY, under the floor (the three runs' mean 0.13%) (`results/gpu/V23_A10_FAST_ABC.md`); The organisms on the card, fully loaded: the seven organisms with an A10 inside, the card offered 1.3 times its full-power capacity, three runs on rented cards: the card's work per energy at 1 copy 6 STEADY, under the floor, 1 power given by the mean of our three runs of 7 organisms; at 10 copies 5 STEADY, under the floor, 2 power given by the mean of our three runs of 7 organisms; at 100 copies 6 one repetition in a run: shown, not judged of 6 organisms (`results/gpu/V23_A10_STACKS_FULL_ABC.md`). Every rental, its cost and what came back is in `docs/RUN_LEDGER.md`.
- **The index's second reading** (service alone, `results/OMNI_INDEX.md`): a second true number for the same tests, not repeated here; this sheet carries the preregistered one.

CHAPTER 55

Every Level on One Page

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

How to read this receipt. Every judged row reads one of three words, decided by what its gauge is for and never by the plus or minus sign of its number. **GAIN**: the gauge moved toward its declared aim against native (more work done, a shorter wait, fewer misses or failures, or a resource cut). **STEADY**: native and Omni-Compass within 0.5% of each other (the mean of the three runs' changes under the 0.5% floor, or no change at all), or the knob is at its limit on native. **LOSS**: the gauge moved away from its aim (less work done, a longer wait, more misses or failures). A resource spent or held (energy, the power drawn and its peaks and swings, machines, memory, processor time, a bill, wear) that fell is a cut, a GAIN; one that rose is **power given**, what Omni-Compass put in to buy the work and the speed shown beside it, always shown and never called a loss; work bought with each unit of a resource (work per energy) that fell is power given too. So a minus can read GAIN (a response time cut) and a plus can read LOSS (failed requests up). A change of 0.5% or more, the mean of the three runs' changes, reads GAIN, LOSS or power given: **in all three of our runs** where A, B and C moved the same way with every interval clear of zero, otherwise **by the mean of our three runs**, with the count of runs beyond the noise beside it; **the runs disagree** names runs that moved 0.5% or more in opposite directions, a test unstable there; **shown, not judged** is a gauge declared shown only. The output follows the input: every reading is the result of the tune, the wiring and the load it names, and where a reading elsewhere differs the first presumption is the wiring (`DISCLOSURES.md`, section 4). The full key, letter by letter: `docs/HOW_TO_READ_THE_RESULTS.md`. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

The founder's order of 17 October: Omni-Compass is shown on top at every level, on every gauge, and every level's gauges should go the same way; where one does not, it is named here and taken to the founder. Each row is built from its result files by `tools/levels.py`; nothing is typed in. A count is of judged gauges (a table's rows that read a word), each under its own table's rule (the three runs, or the realms result's ten seeds); **power given** is a resource put in, shown and never called a loss. Every row names the engine its tables ran on, and no reading is carried from one engine to another.

Level	Engine	Evidence	GAIN	STEADY	power given	LOSS	runs disagree	Goes the other way?
A group of clusters	not run	none yet	–	–	–	–	–	no run at this level yet, real or modelled, on the engine that stands (`k8s_fleet/` holds a model of an earlier engine)

55.1 Each level

55.1.1 The muscle, alone (1,107 muscles, each on its own native controller, under its own load)

Native at this level: each muscle's native controller. Engine: omni-v8. Evidence: S (our model). 421 of the STEADY are at their limit on native (nothing to push). Tables: `results/realms_v5/MUSCLES_V5.csv`.

55.1.2 The organism, the stack: the seven organisms under three loads (own load, the climb, work waiting in line)

Native at this level: every muscle on its native controller, coupled in one body. Engine: omni-v8. Evidence: S (our model). The organism's own reading; inside them no plant did less work or missed its line more often than native, under any load (the realms result's stricter look, plant by plant). Tables: `results/realms_v5/REALMS_V5.md`.

55.1.3 The cluster: real Kubernetes, native its own HPA and scheduler

Native at this level: Kubernetes as shipped with the operator's HPA target. Engine: omni-v26. Evidence: L. Tables: `results/live/V26_ALL_FOUR.md`, `results/live/V26_BATCH.md`, `results/live/V26_CAPACITY.md`, `results/live/V26_FAIRNESS.md`, `results/live/V26_FAULTS.md`, `results/live/V26_TRACE_GOOGLE2011.md`, `results/live/V26_ROBUST_KILL.md`, `results/live/V26_ROBUST_LONG.md`.

Goes the other way:

- V26_ALL_FOUR.md: All four in one run: more work, faster, fewer machines, less energy (load rising 1 to 8 and back): the A/B/C three-run table (Omni v26): response time (ms), 99th percentile (the runs disagree)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- V26_ALL_FOUR.md: All four in one run: more work, faster, fewer machines, less energy (load rising 1 to 8 and back): the A/B/C three-run table (Omni v26): failed requests (%) (the runs disagree)
- V26_ALL_FOUR.md: All four in one run: more work, faster, fewer machines, less energy (load rising 1 to 8 and back): the A/B/C three-run table (Omni v26): pod start wait, total (s) (LOSS)
- V26_ALL_FOUR.md: All four in one run: more work, faster, fewer machines, less energy (load rising 1 to 8 and back): the A/B/C three-run table (Omni v26): pod start wait, mean (s) (LOSS)
- V26_BATCH.md: Batch queue: 240 CPU jobs and cruise: the A/B/C three-run table (Omni v26): response time (ms), 99th percentile (the runs disagree)
- V26_BATCH.md: Batch queue: 240 CPU jobs and cruise: the A/B/C three-run table (Omni v26): time over the response line (% of samples) (the runs disagree)
- V26_BATCH.md: Batch queue: 240 CPU jobs and cruise: the A/B/C three-run table (Omni v26): alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) (LOSS)
- V26_BATCH.md: Batch queue: 240 CPU jobs and cruise: the A/B/C three-run table (Omni v26): pod start wait, total (s) (LOSS)
- V26_BATCH.md: Batch queue: 240 CPU jobs and cruise: the A/B/C three-run table (Omni v26): pod start wait, mean (s) (LOSS)
- V26_BATCH.md: Batch queue: 240 CPU jobs and cruise: the A/B/C three-run table (Omni v26): batch: queue finished (s) (LOSS)
- V26_CAPACITY.md: The capacity test, native and Omni-Compass on top at the same resource cap: the A/B/C three-run table (Omni v26): 1 (the runs disagree)
- V26_CAPACITY.md: The capacity test, native and Omni-Compass on top at the same resource cap: the A/B/C three-run table (Omni v26): 1.5 (LOSS)
- V26_CAPACITY.md: The capacity test, native and Omni-Compass on top at the same resource cap: the A/B/C three-run table (Omni v26): 1.5 (LOSS)
- V26_CAPACITY.md: The capacity test, native and Omni-Compass on top at the same resource cap: the A/B/C three-run table (Omni v26): 2 (LOSS)
- V26_CAPACITY.md: The capacity test, native and Omni-Compass on top at the same resource cap: the A/B/C three-run table (Omni v26): 2 (the runs disagree)
- V26_CAPACITY.md: The capacity test, native and Omni-Compass on top at the same resource cap: the A/B/C three-run table (Omni v26): 3 (the runs disagree)
- V26_FAIRNESS.md: Fairness: a noisy neighbour on the same workers: the A/B/C three-run table (Omni v26): response time (ms), 95th percentile (LOSS)
- V26_FAIRNESS.md: Fairness: a noisy neighbour on the same workers: the A/B/C three-run table (Omni v26): response time (ms), 99th percentile (the runs disagree)
- V26_FAIRNESS.md: Fairness: a noisy neighbour on the same workers: the A/B/C three-run table (Omni v26): time over the response line (% of samples) (the runs disagree)

55.1.6 A physical plant in an independent simulator: buildings, power grids, robot arms, drone swarms

Native at this level: the simulator's own controller, unchanged. Engine: omni-v26. Evidence: independent simulator. Tables: `results/live/V26_CITYLEARN.md`, `results/live/V26_PANDAPOWER.md`, `results/live/V26_MUJOCO.md`, `results/live/V26_SWARM.md`.

55.1.7 The organism with the real cluster inside (the grid, at 1, 10, 100 and on GitHub's machines 1,000 copies)

Native at this level: the organism's native controllers around Kubernetes with its HPA. Engine: older engines' tables; the grid runs again on the engine that stands. Evidence: L, the cluster; S, the organism. No table on the engine that stands yet; the grid's runs on it are dispatched (results/grid_v26/DISPATCHED.json). Tables: `results/live/SIX_KUBE.md`, `results/live/V3_SIX_KUBE.md`, `results/live/V3_BIG_ORGANISM.md`.

55.1.8 The cluster in a cloud: Azure Kubernetes Service, the bill

Native at this level: Azure's own cluster autoscaler and the HPA. Engine: single runs, omni-v5 to omni-v7; one set on omni-v18. Evidence: L, the bill metered. No three-run table yet: eight single runs at the tune-down, machines billed from down 6.5% to up 7.6%, every one STEADY, inside the noise; the fleet (about 1.9 of 4 machines busy) leaves no whole machine to give back; one set of 97 paired repetitions on omni-v18 read the bill up 1.21%, power given, inside the noise (results/live/AKS_STEADY_100_OMNI_V18.md). Tables: `results/live/AKS_BILL.md`, `results/live/raw/run-38981149348/`.

55.1.9 A group of clusters

Native at this level: each cluster's own autoscaler. Engine: not run. Evidence: none yet. No run at this level yet, real or modelled, on the engine that stands (`k8s_fleet/` holds a model of an earlier engine).

CHAPTER 56

The Dossier: Every Result in One Place

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

Every mechanism, harness, receipt and result, read from the files named beside it. Built by `tools/dossier.py` at commit `ccead14a412`. Evidence classes: **T** theorem, **V** verified in code, **S** a model, **L** live software (real Kubernetes), **P** a physical meter. A model is not a meter, and a model written by the people who wrote the law is not an independent test; where a result is a model it says so. The sections below are the record of omni-v3 and the engines before it, each named, every cell's word its own table's; the engine that stands is omni-v26, and its figure of record is the Omni index, **GAIN 20.0%** (its second reading, work and speed alone, GAIN 96.5%), in `results/OMNI_INDEX.md`.

56.1 The mechanism, and proof that it is the one that ran

Check	Result	Where
The whole repository re-runs and checks itself (`python3 verify.py`)	**PASS**	`results/VERIFY_RECEIPT.txt`
The eight-line engine and its six states, fingerprinted (`omnicompass/core.py`)	sha256 `bd615f156169f679…`	`RELEASE_MANIFEST.json`
Python and C++20 twins of every law, proven equal and sealed	seal intact: 17 Python/C++ twins	`results/SEAL.json`
The mechanism's identity against the code	mechanism identity matches the code	`results/MECHANISM_IDENTITY.json`
The engine's convergence to its pole under the bounded command	proved	`docs/TRACKING_THEOREM.md`
Check	**Result**	**Where**
Safety shield: its four properties over 2,000,000 random and adversarial cases run on their own (3 November 2026), 100,000 on every push and 1,000,000 in a full check	0 violations	`tests/test_shield_properties.py`, `verify.py`
Check	**Result**	**Where**

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Check	Result	Where
The compass law (push and pull, 5% cushions, fail up, plug contract) on every muscle, the card and Kubernetes	one law, one file	`omnicompass/compass_law.py`
Every file the results depend on, by fingerprint	written after the check passes	`RELEASE_MANIFEST.json`

The engine is the founder's eight-line equation, integrated by RK4 with the bounded command held across all four stages; it is frozen and fingerprinted, and the C++ twin matches it. The compass law is the outer loop that moves each muscle's own setting: it reads one service position (0 calm, 1 the line), pulls it to the compass's center, pushes against whatever is rising, bounds its force by tanh, fails up past the wall, and writes through a plug that reads every lever once before the first write, reads back every write, yields to any other writer and restores the snapshot at the end.

56.2 Real Kubernetes, Omni v3, every test three times (evidence class L)

Seven tests, ten paired repetitions each, three separate GitHub runs on the frozen engine (A the result, B and C the replications): native Kubernetes (its HPA and scheduler) against the same Kubernetes with Omni-Compass on top, a fresh six-worker cluster per arm, order rotated, the same work sent to both arms. A row reads **GAIN** or **LOSS in all three of our runs** (by what the gauge is for, never by its sign: a response time cut is a GAIN; machines or energy up is **power given**) only when all three runs move the same way with every 95% interval clear of zero and the mean change is 0.5% or more (under that floor it reads STEADY, under the floor); otherwise it reads STEADY, no difference beyond the noise, which is the result (the rule these tables were read by on omni-v3; the 0.5% floor of the one key came on 24 October, `docs/HOW_TO_READ_THE_RESULTS.md`). Each cell gives the word first, then the direction and the size over the three runs, then why. Every Omni arm ends with every setting handed back and read back. Steady runs: A 38013195851 (omni-v3); B 38013200499 (omni-v3); C 38013204648 (omni-v3); the other tests' runs are named in their tables.

Test	Work	Response time (p95; the batch queue's mean)	Machines in service	Energy (declared model)	Failed requests	Table
Steady work in steps	STEADY, equal by design	**GAIN in all three of our runs, down 64% to 66%**	**GAIN in all three of our runs, down 1.7% to**	**GAIN in all three of our runs, down 1.3% to**	STEADY, the same	`results/live/V3_STEADY.md`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Test	Work	Response time (p95; the batch queue's mean)	Machines in service	Energy (declared model)	Failed requests	Table
			2.0%	**1.8%**		
Demand that wanders	not taken	**GAIN in all three of our runs, down 56% to 64%**	STEADY, inside the noise	STEADY, inside the noise	**GAIN in all three of our runs, down 12% to 13%**	`results/live/V3_WANDERING.md`
All four in one run	**GAIN in all three of our runs, up 54% to 68%**	**GAIN in all three of our runs, down 57% to 62%**	STEADY, inside the noise	STEADY, inside the noise	**GAIN in all three of our runs, down 11% to 14%**	`results/live/V3_ALL_FOUR.md`
Fairness, a noisy neighbour	not taken	STEADY, inside the noise	STEADY, the same	STEADY, inside the noise	STEADY, inside the noise	`results/live/V3_FAIRNESS.md`
Faults: machine down, spike, runaway pod, blind probe	not taken	**GAIN in all three of our runs, down 58% to 63%**	STEADY, inside the noise	STEADY, inside the noise	**GAIN in all three of our runs, down 14% to 18%**	`results/live/V3_FAULTS.md`
A queue of batch jobs	not taken	**GAIN in all three of our runs, down 11% to 13%**	**GAIN in all three of our runs, down 16% to 20%**	**GAIN in all three of our runs, down 11% to 14%**	STEADY, inside the noise	`results/live/V3_BATCH.md`
A public day of demand: the Google cluster trace of 2011, replayed one step at a time	not taken	**GAIN in all three of our runs, down 64% to 66%**	**GAIN in all three of our runs, down 7.3% to 9.2%**	**GAIN in all three of our runs, down 5.3% to 6.7%**	**GAIN in all three of our runs, down 11% to 18%**	`results/live/V3_TRACE_GOOGLE2011.md`

Energy on kind is a declared model: the machines are containers on one runner, so a machine out of service cuts modelled watts, not a metered bill. Omni-Compass gives a machine back only after a paired trial shows the service no slower without it (the verdict, `omnicompass/verdict.py`): where a trial passed, the machines in service fell (the steady steps, the batch queue and the Google trace above, a GAIN), and where

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

none passed they stayed at native's and were spent on speed and work (the wandering demand, all four in one run, the faults and the noisy neighbour, STEADY). The v1 tables (`results/live/V1_*.md`, `docs/OMNI_V1.md`) read the same; the sets before v1 are in `docs/history/`.

56.3 A real database: PostgreSQL behind PgBouncer, Omni v3, three runs (evidence class L)

PostgreSQL 16 as shipped behind PgBouncer's shipped pool of 20 is native; omni is the compass law on one knob, the pool size, through PgBouncer's own console, inside the cover [2, 90] (`docs/POSTGRES_PREREGISTRATION.md`). Three paired repetitions a run, three runs, pgbench's own log for the gauges. Runs: A 38054754511; B 38054758150; C 38054761503.

Workload	Work inside the 50 ms line	p95	Connections held open	Host CPU-seconds (the compass's own cost)
`select`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise
`simple_update`	STEADY, inside the noise	STEADY, inside the noise	the runs disagree	STEADY, inside the noise
`tpcb_hot`	STEADY, inside the noise	STEADY, inside the noise	**GAIN in all three of our runs, down 7% to 13%**	STEADY, inside the noise

The compass takes connections back only while the pooler's clients wait for one under 1% of the time and gives them back the moment anyone waits (amendment 2 of `docs/POSTGRES_PREREGISTRATION.md`, 8 October: the first counted set's CPU cost was measured and traced to the harness's own psql launches, not to the pooler, and its first table is kept whole in `docs/history/V3_PGBENCH_set1.md`). Where it reads a cut it is connections held open for the same work, a GAIN, with the host's CPU STEADY (`tpcb_hot`: cut 7% to 13% in all three of our runs); where the add rule buys connections above the operator's setting on a slow write workload (`simple_update`: the most at once up 8% to 12%), that reads power given and counts below 1 in the index. The earlier counted sets are kept whole in `docs/history/V3_PGBENCH_set1.md` to `V3_PGBENCH_set3.md`. Table: `results/live/V3_PGBENCH.md`.

56.4 Real messaging: Apache Kafka, a consumer group's operator-set size, Omni v3, three runs (evidence class L)

Apache Kafka as shipped (one broker, a topic of 8 partitions) with the consumer group at the operator's 2 consumers is native; omni is the compass law on one knob, the consumer count, inside the cover [1, 8], holding the group's own end-to-end latency at 40% of the 500 ms line (`docs/KAFKA_PREREGISTRATION.md`). Three paired repetitions a run, three runs, the consumers' own

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

records for the gauges; the tuning workload is shown and not counted. Runs: A 38054742933; B 38054746778; C 38054750788.

Workload	Work inside the 500 ms line	End-to-end p95	Consumers running (the resource held)	Host CPU-seconds (the compass's own cost)
`tuning` (tuning, shown, not counted)	STEADY, inside the noise	STEADY, inside the noise	STEADY, under the floor (every run under 0.5%; the largest 0.33%)	STEADY, inside the noise
`burst`	STEADY, inside the noise	STEADY, inside the noise	**GAIN in all three of our runs, down 0.8%**	STEADY, inside the noise
`heavy`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise
`light`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise

On the counted set that stands (the brain's own verdict on the knob, amendment 2, run on 10 October: `docs/RERUN_2026-10-10.md`), the consumer count was handed back where the queue allowed: consumers running cut 0.8% on `burst`, a GAIN in all three of our runs (fewer consumers held for the same work), with work, latency and CPU STEADY (on the tuning workload, shown and not counted, the cut was 0.3% in each run: STEADY, under the 0.5% floor); `heavy` and `light` read STEADY on every gauge. No message went unconsumed in any arm; every count was handed back. The earlier counted sets are kept whole in `docs/history/V3_KAFKA_set1.md` and `V3_KAFKA_set2.md`. Table: `results/live/V3_KAFKA.md`.

56.5 A real cache: Redis, the operator's memory ceiling, Omni v3, three runs (evidence class L)

Redis as Ubuntu ships it with the operator's 64 MB ceiling and allkeys-lru is native; omni is the compass law on one knob, the ceiling, inside the cover [16, 512] MB through Redis's own console, growing only while the cache is full and giving a notch back when calm and nothing is evicted (`docs/REDIS_PREREGISTRATION.md`). An application with a declared 5 ms store trip on a miss and a working set that steps up and down; three paired repetitions a run, three runs; the tuning workload is shown and not counted. Runs: A 38054731163; B 38054735302; C 38054739168.

Workload	Work inside the 2 ms line	Cache hit rate	p95	Memory ceiling held, MB (the resource held)	Host CPU-seconds
`tuning` (tuning, shown, not counted)	**GAIN in all three of our runs, up 4.4% to 4.9%**	**GAIN in all three of our runs, up 4.4% to 5.0%**	STEADY, inside the noise	**power given in all three of our runs, up 19% to 26%**	STEADY, inside the noise
`burst`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise
`large`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise
`small`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise

On the counted set that stands (the brain's own verdict on the knob, amendment 2), every untouched workload reads STEADY on every gauge: under the resource objective the verdict left the ceiling where the operator set it, as the preregistration expected before the runs. The tuning workload, shown and never counted, bought a GAIN in work inside the line (up 4.4% to 4.9%: more requests answered inside the line) and in the hit rate (up 4.4% to 5.0%), with memory given (the ceiling held up 19% to 26%, power given). The earlier counted sets are kept whole in `docs/history/V3_REDIS_set1.md` and `V3_REDIS_set2.md`. Table: `results/live/V3_REDIS.md`.

56.6 A real database's storage-engine cache: MongoDB under YCSB, the operator's cache size, Omni v3, three runs (evidence class L)

MongoDB 8.0 as its publisher ships it with the operator's WiredTiger cache of 512 MB is native; omni is the compass law on one knob, the cache size, inside the cover [256, 2,048] MB through the server's own console, growing by notches of 64 MB only while the cache is full and reads are slow, and giving a notch back when calm and the cache holds its working set (`docs/YCSB_PREREGISTRATION.md`; the first counted set's gate was 'nothing evicted', which its amendment 1 of 8 October records as satisfied by a cold cache, and the table named below says which set it is). YCSB's published core workloads with the key space stepping through the cache and past it, drawn uniformly, at 3,000 operations a second from 32 threads; three paired repetitions a run, three runs; the tuning workload (workload A) is shown and not counted. Runs: A 38054777807; B 38054782696; C 38054787517.

All patents, copyrights and trademarks filed in the USA.

Workload	Work inside the 1 ms line	p95	Cache size held, MB (the resource held)	Pages read into the cache	Host CPU-seconds
`tuning` (tuning, shown, not counted)	STEADY, inside the noise	the runs disagree	STEADY, inside the noise	shown, not judged	STEADY, inside the noise
`b`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	shown, not judged	STEADY, inside the noise
`burst`	STEADY, inside the noise	STEADY, inside the noise	**GAIN in all three of our runs, down 10% to 13%**	shown, not judged	STEADY, inside the noise
`c`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	shown, not judged	STEADY, inside the noise
`f`	STEADY, inside the noise	STEADY, inside the noise	**GAIN in all three of our runs, down 13% to 15%**	shown, not judged	STEADY, inside the noise

On this machine the data files sit in the operating system's page cache as well, so a storage-engine miss is a read from memory, not a disk, as disclosed before the run. On the counted set that stands, the cache size held was cut 10% to 15% on `burst` and `f`, a GAIN in all three of our runs, with work inside the line, p95, mean latency and CPU STEADY; `b` and `c` read STEADY on every gauge; the cache was handed back on every omni arm. The earlier counted sets are kept whole in `docs/history/V3_YCSB_set1.md` to `V3_YCSB_set3.md`. Table: `results/live/V3_YCSB.md`.

56.7 A real database's buffer pool: MySQL under sysbench, the operator's InnoDB pool size, Omni v3, three runs (evidence class L)

MySQL 8.0 as Ubuntu ships it with the operator's 512 MB InnoDB buffer pool is native; omni is the compass law on one knob, the pool size, inside the cover [128, 2,048] MB in the server's own 128 MB chunks through its own console, growing only while the pool is full and the server's own statement latency is slow, and giving a chunk back only while the pool's misses are under 1% of its reads (`docs/MYSQL_PREREGISTRATION.md`). sysbench's OLTP scripts as shipped with the tables in use stepping through the pool and past it, at a fixed offered rate from 32 threads; three paired repetitions a run, three runs; the tuning workload (point select) is shown and not counted. Runs: A 38054765202; B 38054768832; C 38054773573.

All patents, copyrights and trademarks filed in the USA.

Workload	Work inside the line	p95	Buffer pool held, MB (the resource held)	Pages read from disk	Host CPU-seconds
`tuning` (tuning, shown, not counted)	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	shown, not judged	STEADY, inside the noise
`burst`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	shown, not judged	STEADY, inside the noise
`read_only`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	shown, not judged	STEADY, inside the noise
`read_write`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	shown, not judged	STEADY, inside the noise
`update_index`	STEADY, inside the noise	STEADY, inside the noise	STEADY, inside the noise	shown, not judged	STEADY, inside the noise

On the counted set that stands (the brain's own verdict on the knob, amendment 3), every untouched workload reads STEADY on every gauge, and the pool was handed back on every omni arm. The earlier counted sets are kept whole in `docs/history/V3_SYSBENCH_set1.md` to `V3_SYSBENCH_set4.md` (the first: 15 of 45 arms not handed back because the plug's restore was issued while the server was still withdrawing the blocks of a shrink, which MySQL ignores; the plug fixed and the fix declared). The update_index work-inside-the-line row counts almost nothing in either arm (a single update's client round trip exceeds the server-side 0.6 ms line) and is disclosed. Table: `results/live/V3_SYSBENCH.md`.

56.8 The bill on a real cloud: Azure Kubernetes Service, Omni v1 (evidence class L, a metered bill)

Azure's own cluster autoscaler is native; omni is the same autoscaler with Omni-Compass idling the machines it gives back; the bill is Azure's own count of machines every 15 s at list price, a fresh cluster per arm, deleted after it (`.github/workflows/aks-metered.yml`, `docs/K8S_COMPASS_PREREGISTRATION.md`, the bill on a real cloud). Transcribed from the receipts they cite:

Test	Fleet	Bill	Response time	Reading	Receipt
Steady load, 5 pairs	4 workers	down 4.7% ($0.0636 to $0.0606), its interval across zero	inside the noise	STEADY, no difference beyond the noise on any gauge	`results/live/V1_AKS_STEADY.md`
A burst sized to the cluster, 5 pairs	4 workers	up 5.0% ($0.1044 to $0.1096), its interval across zero	the 99th percentile down 34% (5,975 to 3,967 ms), clear of the noise in this one run (a GAIN in one run, not a reading of three); p95 inside the noise	the bill STEADY, inside the noise	`results/live/V1_AKS_BURST.md`

One machine is a quarter of a 4-worker fleet, so only a cut of about 30% or more can clear the noise there; the expected machine cut is a few percent. The fleet that can show one machine (40 workers in nine machine families, the subscription's per-family allowance being 10 vCPUs) is preregistered and dispatched on v3; its first dispatches were refused by the subscription's allowances and by Azure's own cluster capacity in eastus before any arm ran, each refusal recorded in the preregistration's amendments.

56.9 Omni-Compass on the modelled card: each base alone, and with Omni on top (evidence class S)

Omni-Compass never runs the card. It sits on the card's own firmware (or on an operator's power cap) and moves the clock ceiling and the power limit, which that base already accepts (`omni_controller/gpu_compass.py`, the same law in `realms/gpu_card.py`). A step down is taken only after a paired trial on the card shows it adds at most 2% to the card's own time on a request (`omnicompass/verdict.py`); where no step passes, the card runs as it does alone.

Each cell is the raw change against the base alone, the geometric mean over the seeds, its sign as it lies (a minus is less energy or a shorter response); it is a model, class S, and carries no word of its own.

Work	Base	Energy, raw change (tuning / fresh)	Median response, raw change	p95, raw change	p99, raw change
Compute-bound	firmware + Omni vs firmware alone	-0.70% / -0.48%	+1.56% / +1.47%	-0.84% / +0.01%	-0.09% / +0.02%
Compute-bound	105 W cap + Omni vs the cap alone	+0.02% / -0.11%	-12.29% / -25.59%	-6.41% / -7.06%	-3.15% / -5.82%

Work	Base	Energy, raw change (tuning / fresh)	Median response, raw change	p95, raw change	p99, raw change
AI token generation	firmware + Omni vs firmware alone	-3.25% / -3.72%	+0.55% / +0.70%	+0.29% / +0.26%	+0.02% / -0.52%
AI token generation	105 W cap + Omni vs the cap alone	-2.10% / -2.38%	+0.07% / +0.12%	+0.03% / -0.02%	-0.06% / -1.57%

Source: `results/sim/gpu_two_wire/RESULT.md` and `fresh/RESULT.md`. The rule, and why the allowance is 2%, is amendment 8 of `docs/GPU_PREREGISTRATION.md`.

56.10 The six organisms at 1, 10, 100 and 1,000 runs and sizes, Omni v3 (evidence class S)

Each organism runs native (its own controllers) and with the compass law on every muscle, same seed, same load, same clock. Size is the number of copies of the organism governed together on one clock (1,000 copies of the four stacked is 1.7 million modelled muscles); runs are the first N of the same paired set, so 1, 10, 100 and 1,000 nest. 78 of the 90 cells are done (`results/scale/GRID.md`); the twelve left (1,000 runs at 100 copies, 100 runs at 1,000 copies) say so in the grid, and 1,000 runs at 1,000 copies is not run, beyond the machines available.

The full grid with every cell: `results/scale/GRID.md`; the receipts, one per size: `results/scale/receipts/`. Work per energy rose in every cell, by about the same at every size (up 0.06% to 0.40%: about 0.07% for Physics and 0.36% for Energy, the four stacked and the tower), every cell under the founder's 0.5% floor, so by the one key it reads STEADY, under the floor; the time over the service line is at or under native's in every cell, so the band-first rule holds and every cell of 10 runs or more reads GAIN within the guardrails by the preregistered rule. Every knob was handed back in every run.

56.11 The 945 muscles and the four realms, Omni v3 (evidence class S)

The catalog (`realms/catalog.csv`): 945 muscles in 59 families, 430 in Compute / AI / Cloud, 376 in Physics / Robotics / Autonomous, 470 in Energy / Facility / Industrial and 440 in Distribution / Specialized (1,716 counting a muscle once per realm, a shared spine of 257; the catalog that stands holds 1,107 muscles in 70 families, `realms/catalog_v5.csv`). Every muscle alone and every organism whole ran on v3 (`results/realms/REALMS.md`; its A, B and C reproduced to the last digit, `docs/history/OWNERS_MANUAL_RESULTS_V1_V3.md`): no muscle with less work per energy, 124 GAIN within the guardrails, 9 that cut energy by trading service for it (GAIN AND LOSS) and the rest STEADY; every organism GAIN within the guardrails by the preregistered rule, its work per energy up 0.1% to 0.3% (under the 0.5% floor, so STEADY, under the floor, by the one key), work STEADY, time over the line not above native's. On v2 the Physics realm and the tower read GAIN AND LOSS (a service traded for

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

energy); the cause was a missing do-no-harm gate on speed knobs, which made v3 (`docs/OMNI_V3.md`). Three independent simulators with their own native controllers are wired the same way and read by the same rule: the power grid (`results/live/V3_PANDAPOWER.md`: energy drawn and net import cut in all 11 SimBench grids with ZIP loads, a GAIN; the energy dissipated in the lines up in 4 and tap operations 4 → 8 a year in one, power given), robot arms (`results/live/V3_MUJOCO.md`: on the Gen3 peak torque cut 29%, tracking error cut 21%, copper heating cut 11% and energy per takt cut 0.8%, each a GAIN in all three of our runs; the iiwa and the UR5e left native by the paired trial, STEADY) and CityLearn (`results/live/V3_CITYLEARN.md`, the 11 districts with electric batteries: the daily peak cut in all 11 and the daily unevenness in 10, a GAIN; electricity bought cut in 4 and under the 0.5% floor in the other 7, STEADY; the highest peak cut in 5 and up in 3, power given; the bill STEADY in 10, seven of them under the floor, and cut in 1). Every row stands in every table, whichever way it went.

56.12 Harnesses and receipts

Harness	What it proves	Receipt
`scripts/kind_paired.sh`, `tools/live_reps.py`, workflow `benchmark-reps`	native against Omni on real Kubernetes, paired on one runner, the reset checked	`results/live/raw/run-*/live-reps/`
`tools/confirm_abc.py` (and `pgbench_abc.py`, `kafka_abc.py`, `redis_abc.py`, `swarm_abc.py`, `mujoco_abc.py`, `pandapower_abc.py`, `citylearn_abc.py`)	three separate runs read by one rule: GAIN or LOSS in all three of our runs (power given for a resource spent that rose), STEADY, the runs disagree; each run's engine checked against the fingerprint	`results/live/V3_*.md`, `V1_*.md`
`tools/omni_version.py`	which frozen engine a checkout or any result's commit carries	`OMNI_V1.json`, `OMNI_V2.json`, `OMNI_V3.json`
`scripts/aks_paired.sh`, workflow `aks-metered`	the same on Azure's managed Kubernetes, Azure's own bill, a fresh cluster per arm, the fleet pre-flighted against the subscription's allowances	`results/live/V1_AKS_*.md`
`tools/run_kil.py`, workflows `six-kube`, `big-organism`, `big-organism-detached`; `t`	the six organisms with a real cluster inside at 1 to 1,000 copies, on GitHub and on a rented machine; the clock rule	`results/live/V1_SIX_KUBE.md`, `V3_SIX_KUBE.md`, `V1_BIG_ORGANISM.md`

Harness	What it proves	Receipt
`verify.py`, `tools/release_manifest.py`	everything above re-runs and checks itself; the manifest fingerprints the result	`results/VERIFY_RECEIPT.txt`, `RELEASE_MANIFEST.json`

The rules for each run were written and committed before it ran (`docs/*_PREREGISTRATION.md`); every row is reported, LOSS included; nothing is read across engine versions.

56.13 What is not yet shown

- A cloud bill or energy cut on real machines: the 4-worker Azure fleet on v1 reads STEADY, inside the noise, as a fleet too small to show one machine must; the steady set of 100 pairs on omni-v18 read the compute bill up 1.2% by the mean of its 97 pairs, its interval across zero: power given, not beyond the noise (`results/live/AKS_STEADY_100_OMNI_V18.md`).
- The real card on the engine that stands: the card runs on rented cards so far ran omni-v21 and omni-v23 (`results/gpu/`: the one card, the one card fully loaded and the eight-card machine); every card result before them ran on a controller since replaced and is obsolete.
- Paid cloud and card runs stop at 100 copies and 100 repetitions (the founder's order of 12 October, to cut the time and the bill); on GitHub's own machines the 1,000 tier stands again (his distinction of 15 October, `scripts/dispatch_grid.py`), a cell beyond a free runner's memory or time listed as pending runner capacity; the v3 cells at 1,000 above stand as they were run.
- The queue in `docs/REGISTER.md` section 4: every open benchmark still to run, in order, each row with its own status.

CHAPTER 57

Paired Runs and Receipts on Your Own System

The method of every benchmark in this manual is the method a reader can use on their own system, and it is deliberately simple: the same system, the same work, native and then omni back to back on the same machines, repeated with the order rotated, each gauge reported with the 95% interval of its paired difference. Pairing is what makes a difference of a few percent visible on a shared machine whose own noise is larger than that: two arms run minutes apart on one runner see the same neighbours and the same hour, so their difference is a difference between arms, while two arms on separate machines differ by about 15% in p95 on their own. The order rotates so that no arm always runs first, warm or cold. The work is held equal by an

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

open-loop load, a fixed rate of requests at fixed moments, so that a lower resource count can never mean that less work was done. The steps below are the whole method.

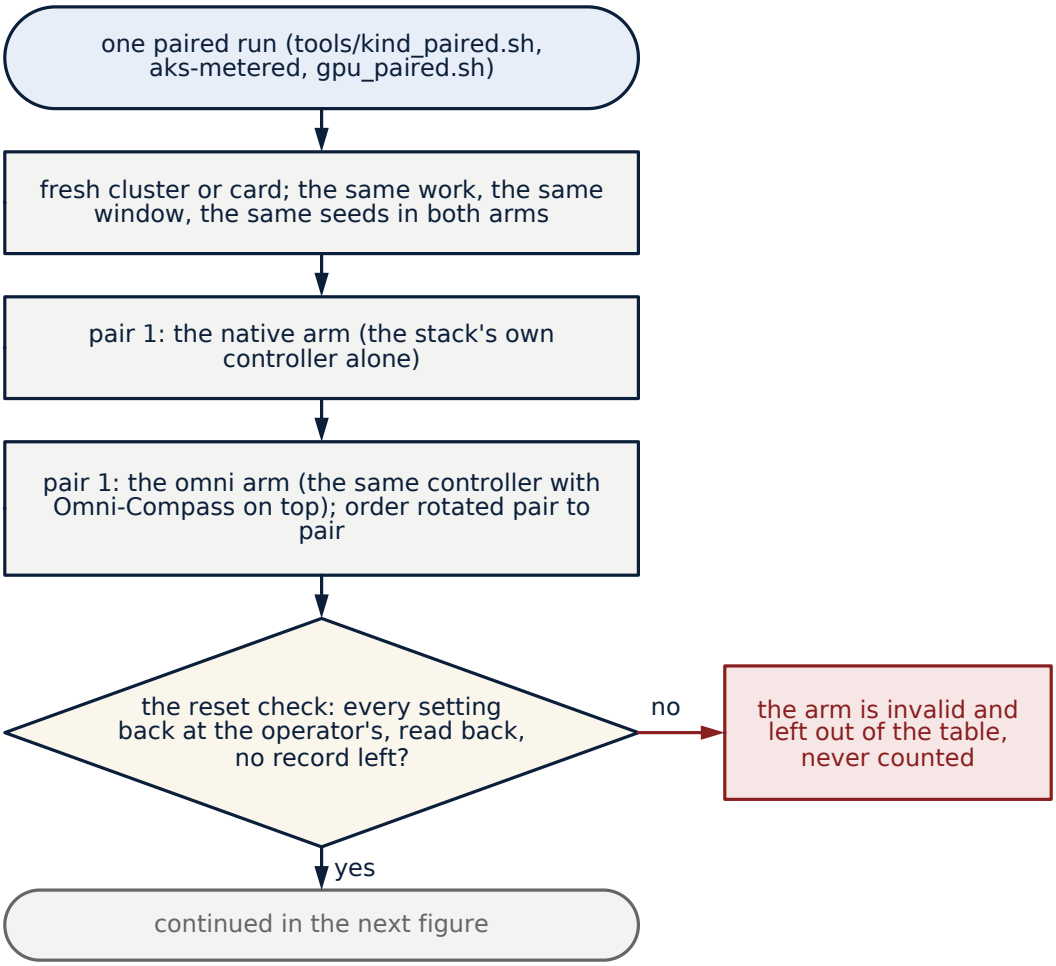

Figure 53. Flowchart: one paired run, the pairs. A fresh cluster or card; the same work, the same window and the same seeds in both arms; each pair runs the native arm (the stack's own controller alone) and the omni arm (the same controller with Omni-Compass on top), the order rotated pair to pair; the reset check after each arm (every setting back at the operator's, read back, no record left) invalidates an arm that fails it, and that arm is never counted. Continued in the next figure.

1. **Paired runs.** Run your service the same way twice, once native and once with Omni-Compass on top, back to back on the same machines, the order rotated, at least 5 times (10 for a result you publish). `scripts/kind_paired.sh` and `tools/live_reps.py` do this on Kubernetes; `scripts/gpu_rented_run.sh` does it on a GPU box, in one command: wire check, smoke, the seven organisms with the card inside, then the preregistered counted run.
2. **The switch drill** after every run: turn Omni-Compass OFF; check every setting is back at its recorded original; turn it ON.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

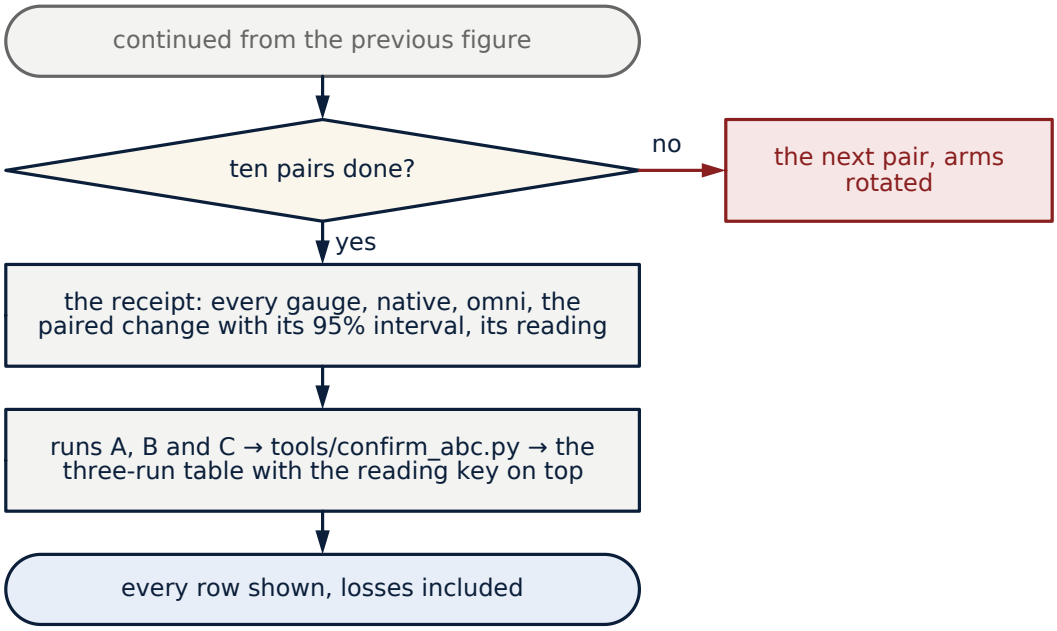

Figure 54. Flowchart: one paired run, from the pairs to the three-run table. After ten pairs the receipt is written: every gauge, native, omni, the paired change with its 95% interval and its reading; runs A, B and C go through tools/confirm_abc.py into the three-run table with the reading key on top; every row is shown, losses included.

3. **The receipt.** Each gauge: native, Omni-Compass, the change, the 95% interval of the difference, and whether the interval excludes zero. A change under 0.5% reads STEADY; a change of 0.5% or more reads its word by the gauge's aim, GAIN, LOSS or power given, and the receipt says whether its interval clears zero (beyond the noise) or not.
4. **The label, by rule written before the run:** SUPERIOR WITHIN GUARDRAILS / ENERGY IMPROVEMENT WITH SERVICE TRADEOFF / NONINFERIOR / INCONCLUSIVE / NOT ESTABLISHED / AWAY FROM ITS AIM / NOT ATTRIBUTABLE / INVALID. Guardrails: work not lower by more than 1%; the share of time outside the service line not higher by more than 1 percentage point. The band-first rule is stricter: no win is claimed while the time outside the service line is above native's.

At scale (modelled). The seven organisms run on GitHub's machines (Actions, workflow `six`) or on any machine (`bash scripts/scale_ladder.sh`) at 1, 10, 100 and 1,000 paired runs and at 1, 10, 100 and 1,000 copies of each organism on one clock. Real Kubernetes runs on GitHub's machines (workflow `benchmark-reps`); the seven organisms with a real cluster inside as one more muscle run in `six-kube` (1 to 100 copies on GitHub) and `big-organism` and `big-organism-detached` (1,000 copies on a rented machine).

5. **Preregister, then run.** The arms, the knob, the cover, the gauges and the readings are written before the first counted run (`docs/*_PREREGISTRATION.md`); the rules are frozen on one tuning case and then

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

applied unchanged to untouched cases. A rule changed after a result is a new version of the engine (Chapter 59), never a footnote.

6. **The clock rule.** An organism must keep its window. `tools/run_kil.py` records how long after the window its last step ended; the report shows it as "organism behind its window (s)", shown and not judged, and marks a repetition **OFF THE CLOCK** when either arm ended more than 5% of the window late, because its last steps then saw a cluster whose load schedule had already ended. The pairing stands (both arms slip alike) and the mark stays on the cell. The remedy is a longer window for that size on that machine, never a faster reading of the same run.
7. **Every row, losses included.** A row that went against Omni-Compass is reported with the others. If Omni-Compass loses, the first suspect is our own wiring, native setup or scoring; that is fixed and the test run again, and the loss stays in the record. A benchmark may be left unpublished; it is never published with rows cut out.
8. **The raw files live with the code.** Every finished run's files (capture, response times, audit log, controller log, one SHA-256 manifest per repetition) are copied into `run-<id>/` on the branch `raw` by the `archive-run` workflow: every hour, by itself, every finished run of every workflow that hands in files, failed runs included (a run id in `.github/archive_request.txt` goes first; a run still going is left for a later pass), and every table names the runs and the commit it was made from. Main's tree carries the code and the tables only, so a clone of it is small; `bash scripts/raw_archive.sh open /run-<id>/` places a run's files at `results/live/raw/run-<id>/`, the path every table names.

How many repetitions, and why. The width of a paired interval shrinks with the square root of the number of pairs, so going from five pairs to ten narrows it by about a third, and from ten to forty by half again. On GitHub's runners, ten pairs of a 900 s window put the interval on work inside the line at ±7.5 to ±14.6 points of native and on p95 at ±16.0 to ±17.8 points (the all-four table on omni-v21, `results/live/V21_ALL_FOUR.md`, run A: work +30.0% with an interval of +22.5 to +37.5; p95 −51.5% with −67.5 to −35.5), wide intervals that still clear zero because the gains are tens of percent; the energy intervals on the same runs are ±0.2 to ±0.3 points, narrow because the gauge is a declared formula over counts of machines, and that is why energy there reads "no difference beyond the noise" honestly rather than as a small claimed gain. A gain of a few percent on a cluster would need forty pairs or more to clear zero at these widths, and the manual does not claim one anywhere a table shows it inside the noise. Three pairs of a 7,200 s window, the long run's shape, give a wider interval on each run but three such runs, each read on its own, still have to agree in sign for a reading the same in all three of our runs. On a stack with a finer knob (connections, consumers, megabytes) the intervals are narrower at three pairs than the cluster's at ten, because the knob moves in hundreds of small steps rather than in whole machines. An operator planning their own receipt should run five pairs first, look at the interval widths on the gauges they care about, and set the count for the published run from those widths, never from the result.

Why the load is open-loop. A closed-loop load generator waits for each answer before sending the next request, so a slower system is offered less work and its throughput "improves" its own latency; two arms under closed-loop load are not doing the same work. An open-loop generator sends requests at fixed moments

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

whatever the system does, so both arms are offered the same work to the request, a queue forms when the system falls behind, and the time over the line and the failed requests record the cost. Every real-stack test in this program (the cluster's load generator, pgbench's rate limit, Kafka's producer at a fixed rate, Redis and YCSB at a fixed target rate) offers its work open-loop, and a lower resource count in the omni arm can therefore never mean less work was asked.

What a receipt looks like. One row per gauge: the gauge's name and direction; native's value and omni's; the paired change as a percentage of native with its 95% interval; the reading. A head naming the system, the knob, the cover, the window, the number of pairs, the order rotation, the engine's fingerprint and the commit; a foot saying whether every arm was handed back and whether any repetition was off the clock. `tools/live_reps.py` prints exactly this for a Kubernetes run and the three-run tools print it for three runs side by side; a receipt from any other tool should be laid out the same way so that a reader of this manual can read it without learning a new shape.

The readings to expect, and what it means when you do not see them. The published tables are the reference an installer reads their own receipt against: not the numbers, which belong to our systems and our loads, but the signs and the words. On omni-v11's tables, the newest until omni-v12's three runs land, on real Kubernetes, ten pairs a run and three runs each (`results/live/V11_*.md`; the CruiseKube row is omni-v10's):

The service	Reads GAIN in all three of our runs	Reads STEADY	Power given
Rightsized with Goldilocks and the VPA's recommender	response time −47% to −48% mean, −61% to −64% at the 95th percentile, −68% to −70% at the 99th; time over the line −98% to −100%; alert minutes −100%; pods started −53% to −61%; the total pod start wait −48% to −63%	machines, failed requests, replicas, the mean pod start wait	parked-worker energy +1.7% to +2.3%
Scaled by KEDA's HTTP add-on	response time −57% mean, −72% to −74% at the 95th percentile, −58% to −62% at the 99th; time over the line −98% to −99%; alert minutes −100%; replicas −11% to −20%	machines, failed requests, pods started, pod start wait	parked-worker energy +1.6% to +2.2%

The service	Reads GAIN in all three of our runs	Reads STEADY	Power given
Scaled by KEDA on CPU and requests	response time −36% to −38% mean, −52% to −53% at the 95th percentile, −57% to −61% at the 99th; time over the line −97% to −100%	machines, failed requests, alert minutes, pods started, pod start wait	parked-worker energy +1.1% to +1.8%; replicas +2% to +3%
Governed by CruiseKube's own recommendations (omni-v10)	nothing: no setting written	every gauge	none
Held at a fixed CPU cap, four caps	nothing: the cap blocks the one lever	completed work and work inside the line at every cap	none

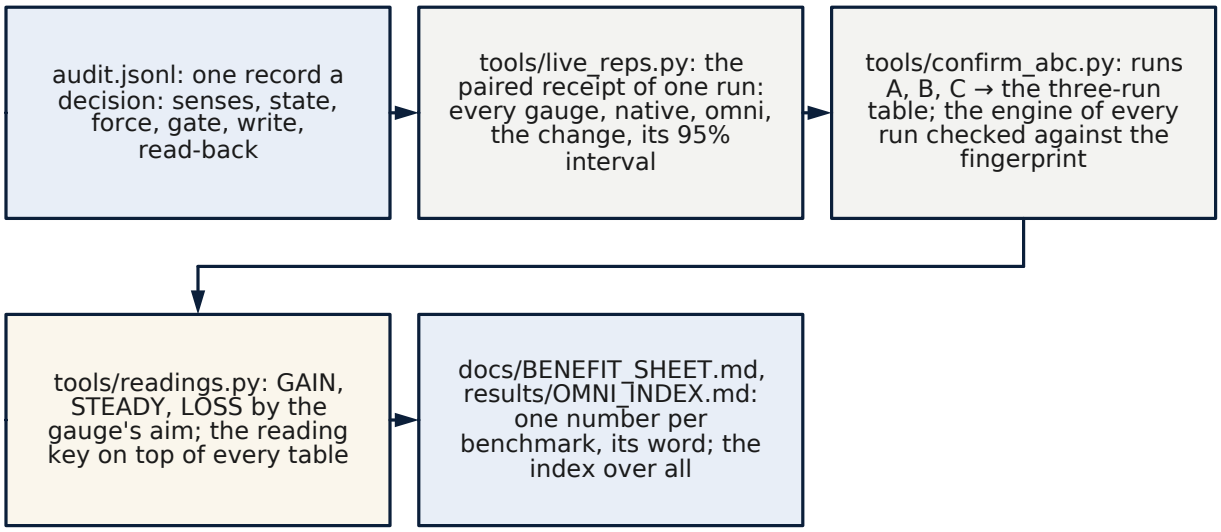
Read your receipt against this table in three steps. **First the words.** A service gauge that reads LOSS on your receipt, where the table reads GAIN or STEADY for the same kind of service, is read as a wiring fault before anything else (`DISCLOSURES.md`, section 4): the feed's freshness and its line, the sensed autoscaler's name, the identity's permissions (Chapter 50), the window's length against the interval widths above. **Second the direction.** Where the table reads GAIN, your receipt should read GAIN or STEADY; a smaller gain is your stack's, not a fault, because the gain is bounded by how far native stood from its own best. **Third the power given.** A resource that rose on your receipt is read beside the work and the speed it bought; a rise with nothing bought is a question for the audit (the Operator's Manual, Appendix L): what did the governor write, and why. Two readings are not faults: STEADY on every gauge where native already runs at the top of its range (the knob is at its limit on native, and the governor leaves it there by design, Chapter 32), and a machine count that does not fall where no machine can be given back without a LOSS (the audit's `node_gate.reason` names the gate that held). What the table cannot give is your number: the same engine on another stack is another result, and it is yours (section 76.7).

CHAPTER 58

Evidence Classes and How to Read a Result

One number, one word. In every table a change keeps its raw sign: a response time that fell reads "-65%", a cache that grew reads "+300%", and the Reading column beside it gives its word, GAIN, STEADY or LOSS, decided by what the gauge is for and never by its sign (the key at the front of this manual): a response time cut 65% is GAIN, a cache grown 300% is **power given**, a fall in work is LOSS. The benefit sheet

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.



(`docs/BENEFIT_SHEET.md`, built from the tables by `tools/benefit_sheet.py` and checked by `verify.py`) turns every gauge the same way round against **each gauge's declared aim** (each preregistration's): plus is a GAIN, minus a LOSS or power given, whatever the gauge measures, and 0% is STEADY, nothing beyond the noise. Beside it every change the same in all three of our runs is written in words, never as a bare sign: "p95 cut 65% (GAIN)", so it cannot be misread against a table that shows the same change as "-65%". One number per benchmark, by the index's own rule, with its word beside it (GAIN, GAIN with power given, GAIN AND LOSS, STEADY, power given or LOSS). The wiring page (section 60.12) uses the same words. A reader who wants one figure for a benchmark reads that sheet; a reader who wants the rows behind it reads the table it names, and reads its Reading column, never the sign alone.

Class	Rung	What it is	What it can show
T / V	E1	deterministic tests, proofs, Python against the C++ twin	the law is what it says, and both languages agree
S	E2	a run on a modelled plant, our own model	whether the law helps the model, and where it breaks
L	E3	real software (Kubernetes on kind), no hardware meter	real decisions on real software; energy there is a declared model
P	E4	a physical meter (the GPU's own power reading)	the hardware's own answer

Read every number with its class beside it. A modelled number is never quoted as a hardware result. When a receipt's energy line is modelled, the receipt says so.

What each class can and cannot carry, with the examples in this manual. A class **T / V** result (the C++ twin agreeing with the Python to 3.6×10^{-15} on 500 trajectories; two million adversarial cases through the shield with zero violations) says that the law is what the text says it is and that both implementations compute it; it says nothing about whether the law helps any machine. A class **S** result (the 1,107 muscles and seven organisms, the organisms at 1,000 copies, the power grid in pandapower, the robot arms in MuJoCo, the buildings in CityLearn, the drones in PyBullet) says what the law does to a published model of a plant under that model's own native controller; it carries exactly the model's fidelity and no more, which is why S results are shown beside the Omni index and never inside it, and why the manual says "the energy is a declared model" on every S line that reports energy. A class **L** result (real Kubernetes on kind, PostgreSQL behind PgBouncer, Apache Kafka, Redis, the organisms with the real cluster inside) says what the law did to real software making real decisions on real requests; the machines, where they are containers on one runner, are counted in machine-hours in service and their energy, where it is reported, is a declared formula, which the table says; the CPU seconds of the host are measured. A class **P** result would say what a physical meter read, and the one P instrument in this program, the GPU's own power reading, has no current result: every earlier card result ran on a controller since replaced and is obsolete. Azure's bill is an L result with a real bill: the machines billed are Azure's own count, the price is Azure's list price, and the energy is still not a meter.

All patents, copyrights and trademarks filed in the USA.

Every table is made by a tool, never by hand; raw records keep their recorded values, every page that shows them uses the words. A reader can follow one run from its audit line to its row in the benefit sheet.

Figure 55. Flowchart: from the audit to the receipt, the table and the one number. The audit (one record a decision) is read by tools/live_reps.py into the paired receipt of one run; runs A, B and C go through tools/confirm_abc.py into the three-run table, each run's engine checked against the fingerprint; tools/readings.py sets GAIN, STEADY or LOSS by the gauge's aim and puts the reading key on top of every table; the benefit sheet and the Omni index carry one number per benchmark. Every table is made by a tool, never by hand.

How to read a row. Every row in every three-run table has the same shape: the gauge and its direction; native's value in run A and omni's value in run A, so the size of the numbers is visible; the paired change in each of the three runs as a percentage of native with its 95% interval; and the reading. Read the reading first, then the intervals, then the sizes. A reading of "GAIN in all three of our runs" with intervals of −0.5% to −0.1% is a small, real effect; a reading of "no difference beyond the noise (3 of 3 runs)" with intervals of −30% to +25% is a test that could not see an effect of that size either way, which is a statement about the test's power, and the manual says so where it applies (the 4-worker Azure fleet). A "LOSS in all three of our runs" row stands in the table, and enters the index as a loss.

A worked reading, from the cache table. Take the Redis table's `large` workload (`results/live/V3_REDIS.md`). The product row, work inside the 2 ms line, reads GAIN in all three of our runs, with the three runs' paired changes each clear of zero and of the same sign; that is the gain. The resource row, the memory ceiling held, reads power given in all three of our runs: Omni held a ceiling of about 256 MB on average where the operator had set 64 MB, in every run, clear of zero. The two rows together are the result: the cache answered more requests inside the line because it was given more memory, and the table says both. A reader who quotes the first row without the second has misread the table, and the index is built so that this cannot happen there: the cache's category enters the one number as a loss (about 0.75 on its own),

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

because the resource it spent is counted at full weight against the work it gained. The CPU row, inside the noise, says the host did not pay in processor time; the failed-request row, zero in both arms, says nothing was refused to get there. Four rows, three directions, one honest sentence: more work inside the line, bought with memory, at no cost in CPU or refusals. That is how every table in Chapter 60 should be read, row by row, before any sentence about it is written.

Three questions to ask of any class L result. First, what was native, exactly: which controller, at which published version, with which settings, and were those settings an operator's or ours? (Every preregistration names them; the broker's native was set at its knee by design and says so.) Second, what did the governor spend: machines, memory, connections, CPU, its own cost? (Every table has the resource rows; a result with a gain and no resource row is not in this program.) Third, who else could have produced the gain: the order of the arms, the warm-up, the runner's neighbour, the clock? (Rotation of the arm order, the warm-up before every window, the paired design on one machine and the clock rule are the answers, and section 60.14 names the residue they do not remove.)

CHAPTER 59

The Frozen Engines and the Three-Run Rule

The engine is frozen, and every freeze has a fingerprint. The engine is the compass law (`omnicompass/compass_law.py`), the live controllers (`omni_controller/`), the realms with their muscles and six organisms (`realms/`), and the runners of the independent simulators (`tools/run_kil.py`, `run_citylearn.py`, `run_pandapower.py`). `OMNI_V1.json` to `OMNI_V25.json` (there is no `OMNI_V4.json`: v4 was a plan, `docs/OMNI_V4_PLAN.md`, never fingerprinted) each hold one SHA-256 per file and one digest over all of them. Any change to a rule, a gain, a guard, a preset or a muscle makes **the next version**, and every result is run again on it; no result is ever read across versions. When the engine is declared final, the engine that stands then is published as Omni-Compass 1.0 and the older fingerprints go to `docs/history` as the road to it, never as a second product.

Engine	What changed	Fingerprint	Results read on it
v1 (`docs/OMNI_V1.md`)	the compass law, the controllers, 656 muscles in 46 families, six organisms; the power-grid runner added inside the version	`ccc7fbdf8b312ed7…`, 38 files	the six Kubernetes tests A/B/C, the six organisms with the cluster inside, the big organisms, Azure steady and burst, CityLearn, the power

python3 tools/omni_version.py --commit <sha>    # the engine at the co
    ↪ mmit any result ran on
```

A commit that holds every engine file but one not yet written reads as that version with the file named ("omni-v1, 37 of 38 files, all v1 bytes; not yet in this commit: tools/run_pandapower.py"): a v1 result for every test but the one that runner serves, which could not have run there. Every table made by rule checks each run's commit against the fingerprint and heads itself with a warning if any run is not the engine it claims or if the three are not separate runs.

The three-run rule (the founder's order of 24 October 2026: any change of 0.5% or more is a change; `tools/readings.py`, `three_run_reading`). Every benchmark runs as **A, B and C**, three separate

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

GitHub runs on the same frozen bytes. With c_i the change of run i in percent of native, the change read is the mean $\bar{c} = (c[A] + c[B] + c[C])/3$, and all three runs are shown beside the reading:

- **GAIN**, **LOSS** or **power given in all three of our runs**: $|\bar{c}| \geq 0.5\%$, and every run moved the same way with its 95% interval clear of zero. The word comes from what the gauge is for, never from the sign; a resource spent that rose reads power given, never a loss.
- **GAIN**, **LOSS** or **power given by the mean of our three runs**: $|\bar{c}| \geq 0.5\%$, but not every run cleared zero the same way; the count of runs beyond the noise stands beside the word ("beyond the noise in 1 of 3").
- **STEADY, under the floor**: $|\bar{c}| < 0.5\%$. **STEADY, the same**: nothing moved.
- **The runs disagree**: runs with $|c_i| \geq 0.5\%$ pointed in opposite directions. The test itself is then unstable on that measure, and it is looked into before anything is claimed.
- A count that must never rise (failed requests, lost messages) has no floor: any rise in any run reads LOSS. Each run's own number wears that run's own word by the same floor; a deterministic simulator's three runs, which reproduce one another, read in all three of our runs from 0.5% up.

The tables are made by rule, never by hand (`tools/confirm_abc.py` for the paired Kubernetes and Azure tests, `pgbench_abc.py`, `kafka_abc.py`, `redis_abc.py`, `swarm_abc.py`, `mujoco_abc.py`, `pandapower_abc.py`, `citylearn_abc.py`; a deterministic simulator's three runs must reproduce each other to the digit, or to the declared tolerance where the simulator is not bit-reproducible across machines, and a score reads "the runs differ" when they do not), and `tests/test_confirm_abc.py`, run by `verify.py`, proves the rule on fixed cases.

Why three separate runs, and why the readings are what they are. One run of ten paired repetitions gives one interval, and an interval from one run can be narrow by luck: the runner was quiet that hour, the order of arms happened to favour one side. A second run on another day and another machine is a replication; a third makes a coincidence expensive. The three runs are separate GitHub runs, which means separate machines, separate hours and separate installations of every dependency, so what agrees across them is not an artefact of one machine. The readings are designed so that there is no reading a reader could mistake for a weaker form of "yes": a row reads "in all three of our runs" only when every run moved the same way with its interval clear of zero; a change of 0.5% or more that some run could not tell from the noise keeps its word, "by the mean of our three runs", with the count of runs beyond the noise beside it; a mean under 0.5% is STEADY; and runs of 0.5% or more that point in opposite directions are reported as a disagreement, which is an instability in the test to be found and fixed, not averaged away. The tables are made by tools, not by hand, and the tools check each run's engine and refuse to mix engines.

The Omni index (`tools/omni_index.py`, `results/OMNI_INDEX.md`) is the one combined number. Every measure of every test is a ratio oriented so that above 1 is a GAIN for Omni-Compass on top of native: work (more), speed (a lower response time), machines (fewer), energy (less). A test's index is the geometric mean of its ratios, a category's the geometric mean of its tests, the headline the geometric mean of the real categories, each weighted the same. A measure enters only as its three-run reading allows: GAIN, LOSS or power given in all three of our runs counts as the geometric mean of the runs' ratios; anything else counts as

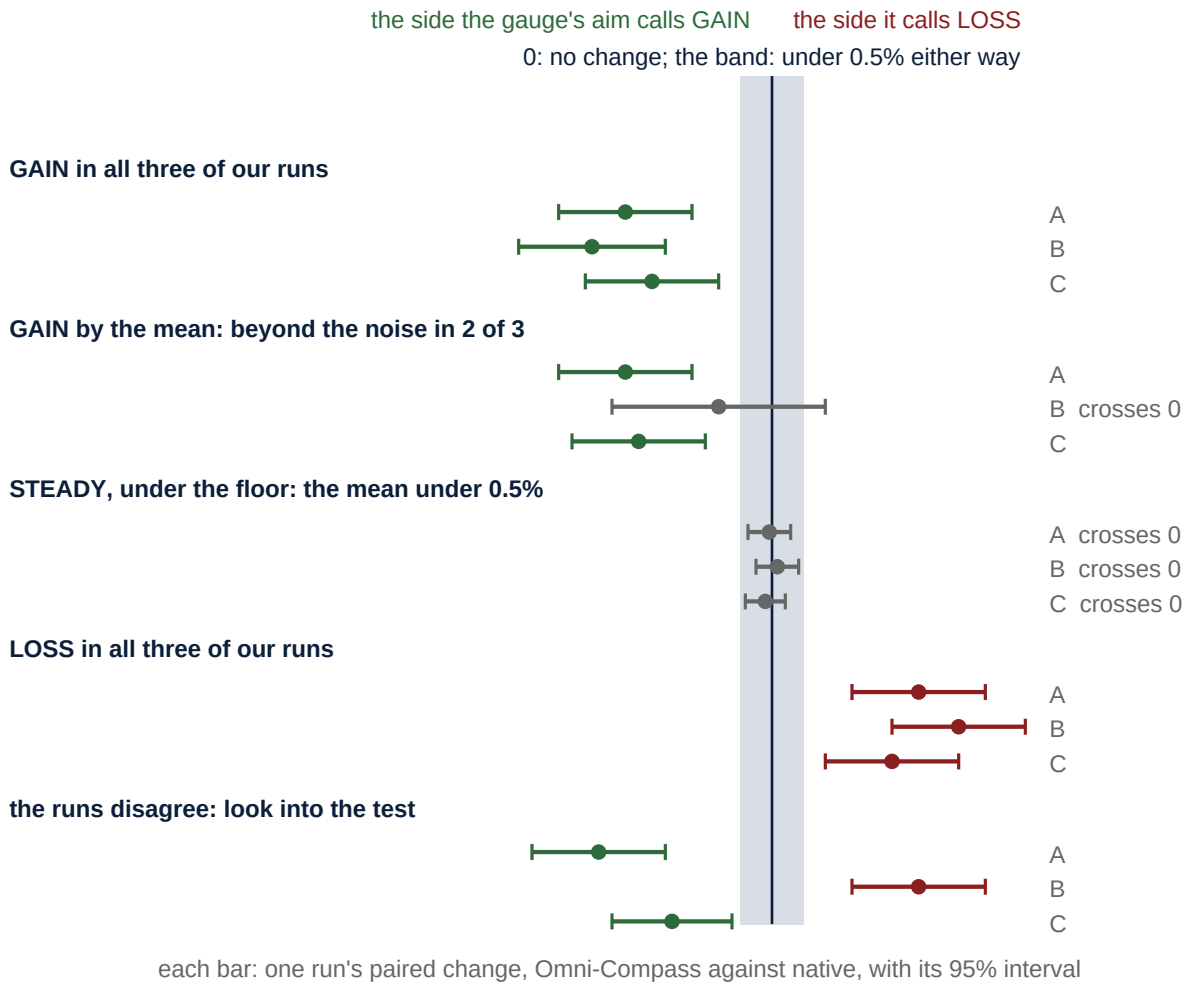

Figure 56. The three-run rule, read from the intervals, as drawn before the rule of 24 October (since then a mean change under 0.5% is STEADY and a change of 0.5% or more whose intervals do not all clear zero reads its word by the mean of our three runs). Each row is one gauge; each bar is one run's paired change of Omni-Compass against native with its 95% interval.

GAIN or LOSS in all three of our runs: the same side in all three, every interval clear of zero. STEADY, as drawn: at least one interval includes zero. The runs disagree: clear intervals on both sides, an unstable test to be looked into. Which side reads GAIN is set by what the gauge is for: for time waited, misses and failures a fall; for work done a rise; for a resource spent a fall is a cut and a rise is power given, never a loss.

exactly 1 (STEADY, the runs disagree, and a word read by the mean of our three runs), so nothing that did not hold in every run is claimed either way. Modelled muscles are shown beside the index, never inside it.

Why geometric means, and three rules a referee should check. A ratio of 2 and a ratio of 0.5 are the same size of effect in opposite directions; their arithmetic mean is 1.25, which would read as a gain, while their geometric mean is 1, which is the truth. Geometric means also make the index indifferent to which side a gauge is written from (work per machine or machines per unit of work), and they let a category of three tests

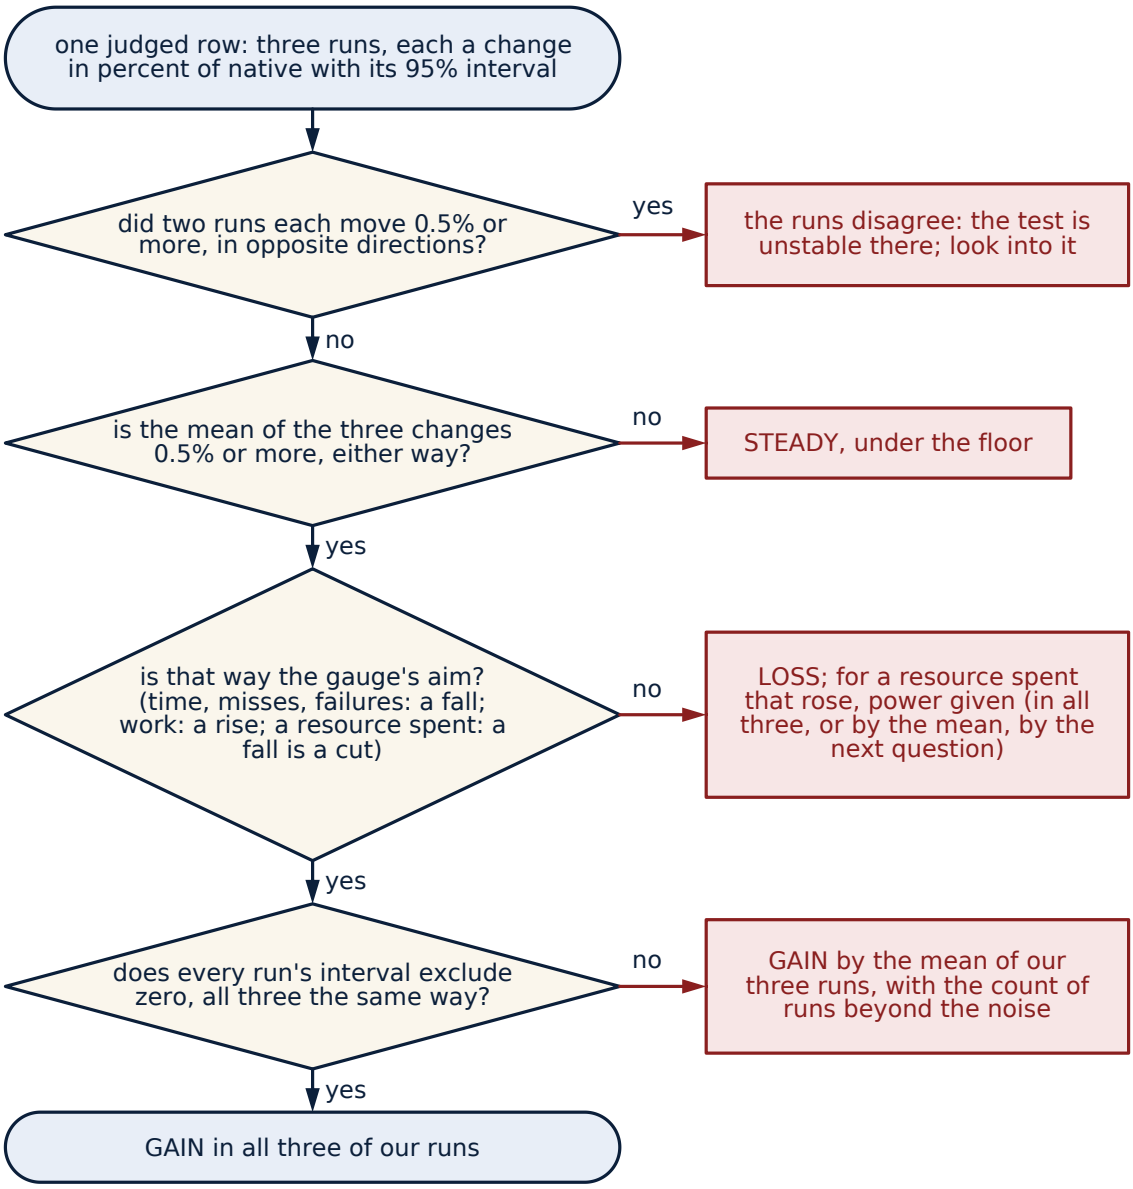

Figure 57. Flowchart: the three-run reading rule, as a procedure, as drawn before the rule of 24 October. For one judged row: if any of the three intervals includes zero the row reads STEADY, with the count of runs it holds in; if the three clear intervals do not point the same way the runs disagree and the test is unstable there; if they point the gauge's way the row reads GAIN in all three of our runs, and the other way LOSS, except for a resource spent that rose, which is power given.

Since 24 October the 0.5% floor on the mean of the three runs comes first, and an interval across zero no longer makes a row STEADY: it reads its word by the mean of our three runs, with the count beyond the noise (the text above).

and a category of six weigh the same. Three rules follow from the design and can be checked in the tool: first, the tuning workload or tuning cell of every benchmark is excluded, because the rules were fitted on it; second,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

no row inside the noise contributes anything, in either direction, so the index can never be moved by a run that happened to be quiet; third, the categories are the real ones only (Kubernetes, the database, messaging, the cache as it lands, Azure and the card as their tables land), each weighed the same whatever the number of tests inside it. The index therefore answers one question only: across every real category the same in all three of our runs, what did Omni-Compass on top of native deliver in more work, faster answers, fewer machines and less energy, counting the resources it spent against it. The index page says, where a ratio is large, why it is: in messaging, native sat at nine tenths of its measured capacity by design, so its queue grew at the high steps and Omni's did not, and a queue kept short against a queue that grows is a large ratio in response time.

CHAPTER 60

Results to Date

Every result below, read together in one place with what each shows and what it does not, by evidence class and engine, newest first: *The Receipts, in Their Totality* (`docs/THE_RECEIPTS.md`). The chip's own receipts (an A10 and an A100, each its own power meter) are read in section 60.6 and `results/TWO_BILLS.md`.

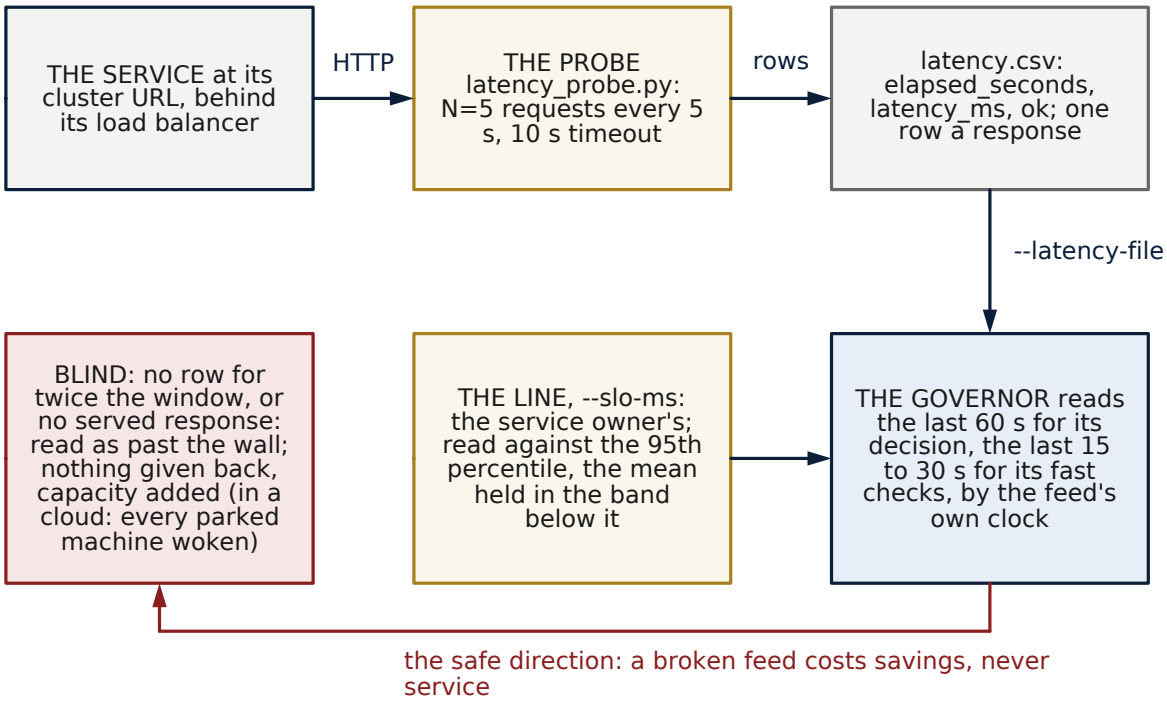
Every result below is Omni-Compass **on top of** a native system against the same native system alone, with the same work in both arms, read by the three-run rule of Chapter 59, on the engine named. Losses are in the tables beside the gains. The whole list, benchmark by benchmark with its native engine, its knob, its gauges and its file, is `docs/REGISTER.md`; the program that takes every benchmark to full size is `docs/PROOF_PROGRAM.md`.

How to read the chapter. Each section names the stack, the native controller Omni-Compass sat on, the one knob it moved, the result file in `results/live/` or `results/`, the three GitHub run numbers (or the rented machine's start and collect runs) and the engine version those runs were on; a reader can open the file, find the runs under the repository's Actions tab, and check the commit with `tools/omni_version.py --commit`. The figures quoted in prose are the table's figures and no others; where a range is given ("−13% to −37%") it is the span of the three runs' point estimates, not an interval. Every row of every table has one of the readings of the three-run rule (Chapter 59): GAIN, LOSS or power given in all three of our runs or by the mean of our three runs (with the count beyond the noise), STEADY under the floor or the same, or the runs disagree; rows that are shown and not judged say so and why. Every table was read again from its own data by the rule of 24 October (`tools/reread.py`); where a figure quoted below was written before that, its table's own word now stands. A loss is written in the same sentence as the gain it came with, never in a footnote, and the index (section 60.11) counts every loss in all three of our runs against Omni at full weight.

Two cautions a referee should hold while reading. The real-software results (evidence class L) were taken on GitHub's shared runners or on single rented machines, with the host's CPU-seconds as the only measure of

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

energy and no meter on the wall; Chapters 57 and 58 say what that does and does not allow. And the modelled results (evidence class S) are reported as what they are, our own plant models run whole, and are never summed with the live ones; the index is built from the real categories alone, and the modelled realms sit beside it as a separate finding about the law's coherence at scale.



60.1 Real Kubernetes: seven tests, ten pairs each, three runs each

The six Kubernetes tests were designed to ask six different questions of the same cluster, and they are read together; a seventh, added on 8 October, asks the same questions under a day of demand that somebody else measured. The cluster is kind: a real Kubernetes control plane and six worker nodes as containers on one 4-core GitHub runner, with a real metrics-server, a real HPA at the operator's target of 50% CPU, a real PHP service behind a NodePort, and a real load generator whose replica count steps through a schedule identical in both arms. A real probe times HTTP requests every five seconds from outside the service. Native is that cluster with its HPA alone; omni is the same cluster with the compass law on the HPA target inside [30%, 50%] and on the machines through the release gate and the verdict. Both arms start from the same fresh cluster, run for 900 s after a 120 s warm-up, and end with the reset check.

Written from the newest three-run table of each test by `python3 tools/results_chapter.py`, from the benefit sheet's record (`results/BENEFIT_SHEET.json`); `verify.py` fails a push where it differs. Each line names the test, its table and the engine its runs were on, its reading, and then every judged gauge with the span of the three runs' changes (the span of the three point estimates, not an interval), in the key's words. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

- **Steady work** (`results/live/V26_STEADY.md`, omni-v26): **GAIN, power given**, by the index's rule 31.5% GAIN. Mean response cut 47% to 50% (GAIN); p95 cut 66% to 67% (GAIN); p99 cut 71% to 73% (GAIN); time over the line cut 98% to 100% (GAIN); alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) cut 100% (GAIN); pods started cut 4% to 29% (GAIN); pod start wait, total (s) cut 7% to 35% (GAIN); pod start wait, mean (s) cut 2% to 10% (GAIN); replicas up 3.2% to 4.7% (power given).
- **Faults** (`results/live/V26_FAULTS.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 34.3% GAIN. Mean response cut 36% to 50% (GAIN); p95 cut 54% to 62% (GAIN); p99 cut 31% to 62% (GAIN); time over the line cut 20% to 26% (GAIN); alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) cut 11% to 13% (GAIN); pod start wait, total (s) up 67% to 92% (LOSS); replicas up 26% to 30% (power given); pods started up 65% to 94% (power given).
- **Demand that wanders** (`results/live/V26_WANDERING.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 27.6% GAIN. Mean response cut 36% to 41% (GAIN); p95 cut 48% to 54% (GAIN); time over the line cut 29% to 37% (GAIN); alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) cut 22% to 29% (GAIN); pod start wait, total (s) up 108% to

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Feed two: the service's own timings (an ingress, a mesh, the application's histogram) written in the same three columns, measured at the same place as the line, never pre-smoothed. One feed for one governor.

Figure 58. Wiring schematic: the response-time feed and the line. The probe times real requests to the service and writes one row a response to latency.csv (elapsed_seconds, latency_ms, ok); the governor reads the file by its own clock, the last 60 s for its decision and the last 15 to 30 s for its fast checks, against the line the service owner wrote (--slo-ms).

A feed that has not advanced for twice the window, or holds no served response, reads as blind, and a blind sense is read as past the wall: nothing is given back and capacity is added (in the cloud mode every parked machine is woken), the safe direction. A second feed, the service's own timings, may be written in the same three columns, measured at the same place as the line and never pre-smoothed.

133% (LOSS); pod start wait, mean (s) up 9% to 21% (LOSS); replicas up 24% to 31% (power given); pods started up 67% to 131% (power given).

- **All four at once** (`results/live/V26_ALL_FOUR.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 28.6% GAIN. Work inside the line up 31% to 50% (GAIN); mean response cut 34% to 43% (GAIN); p95 cut 42% to 53% (GAIN); time over the line cut 30% to 35% (GAIN); alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) cut 19% to 26% (GAIN); pod start wait, total (s) up 107% to 167% (LOSS); pod start wait, mean (s) up 15% to 35% (LOSS); replicas up 5% to 15% (power given); pods started up 75% to 87% (power given).
- **A queue of jobs** (`results/live/V26_BATCH.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 10.2% GAIN. Machines cut 13% to 28% (GAIN); machine-hours cut 13% to 28% (GAIN);

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

standby-model energy cut 9% to 19% (GAIN); mean response cut 5.4% to 9.9% (GAIN); p95 cut 0.3% to 2.1% (GAIN); machines after the queue cut 22% to 45% (GAIN); alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) up 1.0% to 3.6% (LOSS); pod start wait, total (s) up 129% to 1700% (LOSS); pod start wait, mean (s) up 14% to 800% (LOSS); queue finished up 2.4% to 3.1% (LOSS); replicas up 1% to 25% (power given); pods started up 100% (power given).

- **A public day of demand (Google 2011)** (`results/live/V26_TRACE_GOOGLE2011.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 37.4% GAIN. Mean response cut 49% to 50% (GAIN); p95 cut 60% to 64% (GAIN); p99 cut 47% to 54% (GAIN); time over the line cut 76% to 77% (GAIN); failed requests cut 8% to 15% (GAIN); alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) cut 60% to 68% (GAIN); pod start wait, total (s) up 163% to 173% (LOSS); replicas up 14% to 26% (power given); pods started up 126% to 166% (power given).
- **A noisy neighbour** (`results/live/V26_FAIRNESS.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 2.6% LOSS. Mean response cut 0.4% to 8.0% (GAIN); p95 up 5% to 11% (LOSS); pod start wait, total (s) up 10% to 23% (LOSS); second app: response time (ms), 95th percentile up 0% to 12% (LOSS); second app: failed requests (%) up 2.0% to 3.3% (LOSS); replicas up 2.0% to 4.0% (power given); pods started up 7% to 18% (power given).

On top of Kubernetes with its add-ons (KEDA two ways), and on top of Goldilocks and of CruiseKube: section 60.2.

60.2 On the add-ons: Goldilocks, CruiseKube and KEDA

Native is the add-on as its project ships it, on the same kind cluster as section 60.1, the served image pulled onto every worker before each arm; Omni-Compass sits on top of it, never in its place. Each test's own table carries the governor's inputs (the settings commands it wrote, the targets it held) beside the service's outputs, shown and not judged.

Written from the newest three-run table of each test by `python3 tools/results_chapter.py`, from the benefit sheet's record (`results/BENEFIT_SHEET.json`); `verify.py` fails a push where it differs. Each line names the test, its table and the engine its runs were on, its reading, and then every judged gauge with the span of the three runs' changes (the span of the three point estimates, not an interval), in the key's words. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

- **A service rightsized by Goldilocks and the VPA's recommender, Omni-Compass on top, ten pairs, three runs** (`results/live/V26_GOLDILOCKS.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 10.2% GAIN. Parked-worker energy up 1.1% to 1.7% (power given); standby-model energy up 1.1% to 1.7% (power given); mean response cut 34% to 37% (GAIN); p95 cut 39% to 45% (GAIN); p99 cut 36% to 38% (GAIN); time over the line cut 84% to 86% (GAIN); replicas up 29% to 35% (power given); pods started up 73% to 100% (power given); pod start wait, total (s) up 96% to 149% (LOSS); pod start wait, mean (s) up 12% to 22% (LOSS).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

- **A service rightsized by CruiseKube applying its own recommendations, Omni-Compass on top, ten pairs, three runs** (`results/live/V26_CRUISEKUBE.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 1.3% LOSS. Machines cut 0.3% to 5.3% (GAIN); machine-hours cut 0.5% to 5.1% (GAIN); standby-model energy cut 0.0% to 3.6% (GAIN); mean response up 0.5% to 1.8% (LOSS); p95 up 0.7% to 3.1% (LOSS); p99 up 5.8% to 8.9% (LOSS); pods started up 0% to 20% (power given); pod start wait, total (s) up 0% to 14% (LOSS).
- **With its add-ons: KEDA's HTTP add-on on the live requests in flight, Omni-Compass on top, ten pairs, three runs** (`results/live/V26_KEDA_REQUESTS.md`, omni-v26): **GAIN, power given**, by the index's rule 26.4% GAIN. Parked-worker energy up 1.7% to 1.8% (power given); standby-model energy up 1.7% to 1.8% (power given); mean response cut 46% to 49% (GAIN); p95 cut 41% to 49% (GAIN); p99 cut 21% to 23% (GAIN); time over the line cut 64% to 70% (GAIN); alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) cut 59% to 71% (GAIN); replicas cut 8% to 14% (GAIN).
- **With its add-ons: KEDA on the CPU target and the live requests in flight, Omni-Compass on top, ten pairs, three runs** (`results/live/V26_KEDA_CPU_REQUESTS.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 7.3% GAIN. Parked-worker energy up 1.4% to 1.6% (power given); standby-model energy up 1.4% to 1.6% (power given); mean response cut 28% to 29% (GAIN); p95 cut 33% to 40% (GAIN); p99 cut 27% to 34% (GAIN); time over the line cut 54% to 82% (GAIN); replicas up 22% to 31% (power given); pods started up 56% to 74% (power given); pod start wait, total (s) up 36% to 112% (LOSS).

60.3 Omni-Compass direct: the three arms, three runs

The founder's order of 23 October: native, Omni-Compass on native and Omni-Compass direct, always shown together. The test is Omni-Compass's own orchestrator (`omni_orchestrator/`, `docs/OMNI_ORCHESTRATOR.md`): native is Kubernetes' published autoscaling rule on the muscles, written by us as the yardstick (brain `yardstick`); Omni-Compass on native is Omni-Compass on top of that rule (brain `omni_native`); Omni-Compass direct is Omni-Compass alone on the muscles, no Kubernetes (brain `omni`). Three runs on GitHub's own machines, A, B and C from one commit (`9d2bea96a878`, engine omni-v21, runs 40474220398, 40474223636, 40474227699), the full form: 18 steps of 25 s, the clients stepping 1 2 3 2 3 4 …, the busy room rule; each pair read by the one key, paired by step (`results/orchestrator/V21_THREE_ARMS_ABC.md`, class L):

Pair	Gauge	Three runs	A	B	C		
Omni on native against native	Work (requests a step)	**GAIN in all three of our runs**	GAIN, up 10.3%	GAIN, up 8.2%	GAIN, up 7.0%

table: Omni direct against Omni on native, Work (requests a step). The test runs again on the engine that stands. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

60.4 The organisms with the real cluster inside, and the grid

The newest tables of the organisms with the real Kubernetes cluster inside are omni-v3's; they run again on the engine that stands, and until their tables land these are omni-v3's.

Written from the newest three-run table of each test by `python3 tools/results_chapter.py`, from the benefit sheet's record (`results/BENEFIT_SHEET.json`); `verify.py` fails a push where it differs. Each line names the test, its table and the engine its runs were on, its reading, and then every judged gauge with the span of the three runs' changes (the span of the three point estimates, not an interval), in the key's words. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

- **The six organisms with the real cluster inside, 10 and 100 copies** (`results/live/V3_SIX_KUBE.md`, omni-v3): **GAIN, power given**, by the index's rule 5.3% GAIN. P95 cut 32% to 52% (GAIN); time over the line cut 8% to 36% (GAIN); replicas up 0.6% (power given); failed requests cut 8.4% to 8.5% (GAIN); parked-worker energy cut 0.3% (GAIN); standby-model energy cut 0.3% (GAIN).
- **The big organisms with the real cluster inside, 1,000 copies on Azure** (`results/live/V3_BIG_ORGANISM.md`, omni-v3): **GAIN**, by the index's rule 155.0% GAIN. P95 cut 95% to 98% (GAIN); p99 cut 97% to 98% (GAIN).

The grid (the seven organisms at 1, 10 and 100 copies, each at 1, 10 and 100 runs). Its one written report is engine omni-v5's (`results/grid_v5/GRID.md`); its modelled squares read, in the report's own summary with its signs put in words: modelled, 36 of 36 squares of 10 and 100 runs GAIN (fewer misses); the 18 single runs: 18 with fewer misses; work STEADY, the same (raw +0.000%); energy STEADY, up 0.000% to 0.065% (under the 0.5% floor). The squares with the real cluster inside are read gauge by gauge in the same report. The grid has been sent on every engine since, omni-v6 to omni-v26 (`results/grid_v*/DISPATCHED.json`), and no report of those runs has been written yet; until one is, the grid is read only on omni-v5.

60.5 The bill on a real cloud

Azure Kubernetes Service, with Azure's own cluster autoscaler as native, is the one cloud read so far; Google and Amazon are wired as Azure is and not yet run (their queues switched off). What a bill must show and how it is read is section 60.6 and `results/TWO_BILLS.md`.

Azure Kubernetes Service, the steady set of 100 paired repetitions on omni-v18: the bill, the machines, the service (`results/live/AKS_STEADY_100_OMNI_V18.md`; run 40069633316, engine omni-v18, 97 paired repetitions read). The record's own reading, carried from it by `python3`

All patents, copyrights and trademarks filed in the USA.

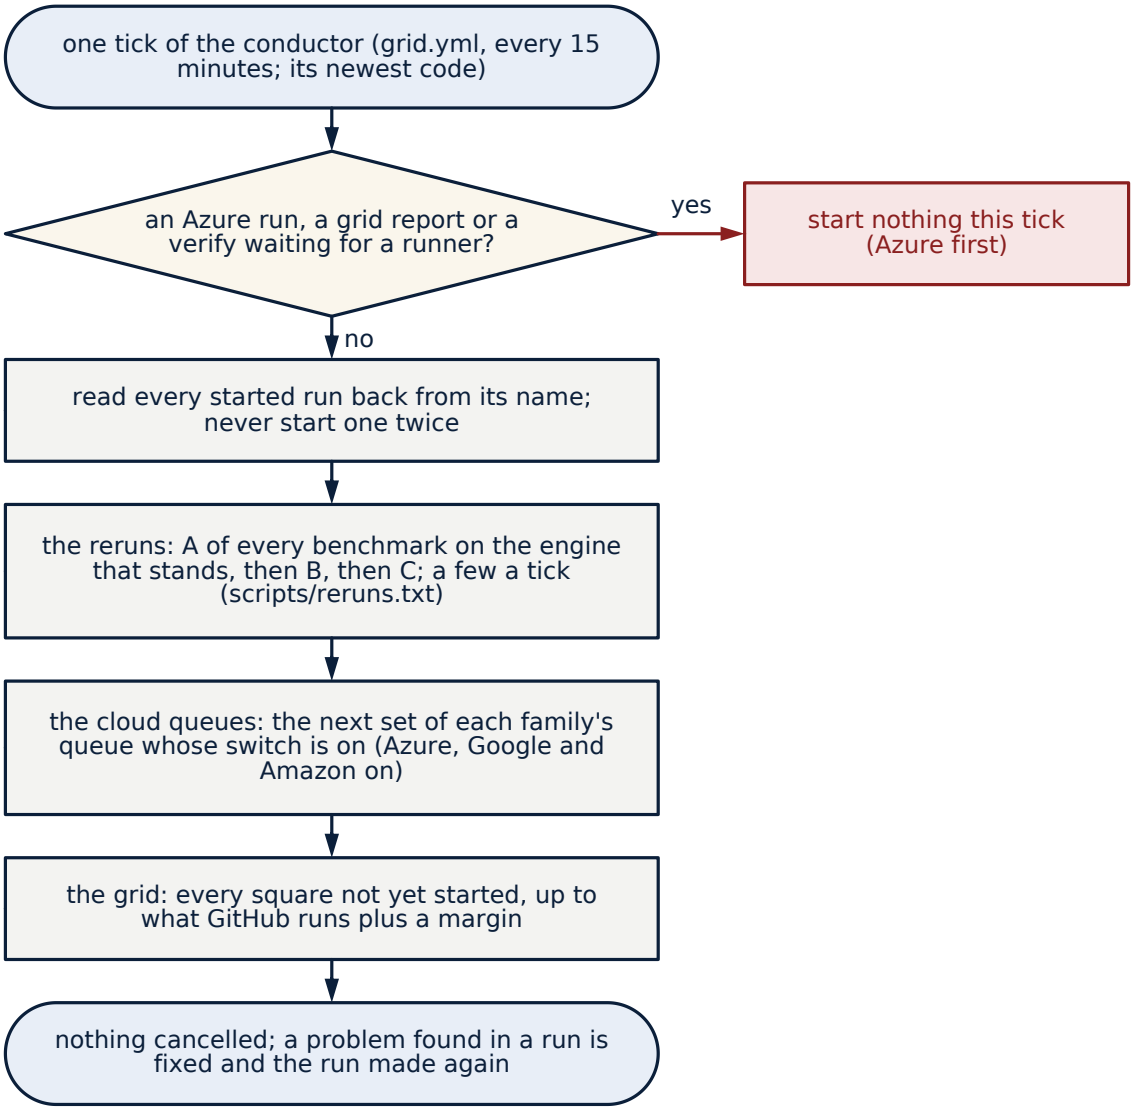

Figure 59. Flowchart: one tick of the grid conductor (grid.yml, every 15 minutes, on its newest code). It starts nothing while an Azure run, a grid report or a verify waits for a runner; it reads every started run back from its name and never starts one twice; it releases the reruns of every benchmark on the engine that stands (A of every benchmark, then B, then C), the next set of each cloud queue whose switch is on, and every grid square not yet started, up to what GitHub runs plus a margin. Nothing is cancelled.

`tools/results_chapter.py`, its retired word for no difference beyond the noise written as the key's STEADY: the compute bill at list price up 1.2% by the mean of the 97 pairs, its 95% interval across zero (−$0.0007 to +$0.0021 a repetition): power given, not beyond the noise; machines billed up 1.2%, the same; the response time's 99th percentile GAIN (down 11.0%, its interval clear of zero); every other service gauge STEADY or not beyond the noise; failed requests up 3.9% by the mean, its interval across zero. The stopping rule read the bill at every look and never decided it, so the set ran to the paid cap of 100.

60.6 The cloud is a wire: three pieces, two places, one organism (a composition, class S of L and P)

What the record shows in each place so far (the words for each place, and what each benchmark must show, are written once and carried word for word in this manual, the README and `DISCLOSURES.md`, section 10): at the software end the benefit, the Omni index over work, speed and machines (`results/OMNI_INDEX.md`; composed layer by layer in `results/WHOLE_SYSTEM.md`), with no bill in it; on bare metal, the A10's own bill and meter on omni-v23 (`results/TWO_BILLS.md`, `results/gpu/V23_A10_CAP_FULL_ABC.md`), fully loaded: the bill STEADY, the work done inside it the runs disagree (up in two runs, down in the third, that run's lost work on the next version's list), the chip's energy for each request served GAIN in all three of our runs (the A100's three runs on omni-v21 read work and energy STEADY, `results/gpu/V21_A100_CAP_ABC.md`); through the cloud, Azure's steady set on omni-v18, 97 paired repetitions (`results/live/AKS_STEADY_100_OMNI_V18.md`) reads the bill up 1.2%, inside the noise, and the 99th percentile GAIN: it holds. What the benefit cost the chip, the energy and the wire is listed row by row in section 3b of `results/WHOLE_SYSTEM.md`. In the cloud the yardstick is the work per dollar: the work answered within the line divided by the bill, against native; a bill that rises is power given beside the work it bought, and the work must rise more.

The people, counted: the oversight line (`results/OVERSIGHT.md`, written by `tools/oversight.py` from the tables). The Omni index counts work, speed and machines, never a person; the receipts count the people too, in both arms. Across the 37 real Kubernetes tests of omni-v26, the minutes an on-call page would be open (the 3 a.m. call) went down 11.0%, fewer in 13 tests and to none in 3, and down in each of our three runs beyond the noise (GAIN in all three of our runs), while the governor turned the knobs itself (227; 207; 226 settings an hour in runs A; B; C, no person touching either arm). Counted as pages from the same runs' raw files by the rule written before the count, the pages a person would have been sent went down 12.2% (GAIN by the mean of our three runs, beyond the noise in 2 of 3; `results/OVERSIGHT_PAGES.md`): fewer pages, each open about as long. In the bill it is the people line, b = s(people) · b(people) at the owner's own share: at the founder's example of 7%, down 0.8% of the whole bill. It is not added to the index (a share of a bill and a reading of work and speed do not add), and it removes no person: a person keeps the switch.

A cloud is just a wire (the founder's words of 24 October: "a big bold statement", carried in every manual). It is the wire between the software end (the owner's programs, Kubernetes and the open-source orchestrators, managers and autoscalers that carry the work) and the hardware end (the bare metal: the GPU chips, the Linux racks, the data center, on site or off site). Omni-Compass sits on all three pieces where a system lets it (the software end in either place, the chip only on bare metal); a system itself runs in one of two places, bare metal or the cloud (the founder's order of 1 November). The wire makes no benefit of its own. Until 31 October every cloud run in this repository was set on the wire alone (the tune-down on the machines only, the pods exactly native's), so it could only park machines the cloud's own autoscaler already made, after its own trial, and show at most a small cut in the bill of the wire. From 31 October (the founder's order of that day) every

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

cloud set runs the whole engine at the max on the cloud's cluster, the software end, and what its receipt must show is that the engine holds there: no judged gauge LOSS against native, the work per dollar read beside the bill (the founder's words of 31 October, night: "We just need to show we hold"). The benefit is shown where it lives, at the software end, and explained through the wire. The energy and the throughput gained at the bare metal are the provider's and not under it; they are measured where Omni-Compass sits on the chip and composed with the wire into one organism and one bill by the product law $R(g) = \prod_\ell R_\ell(g)$, $\log R = \Sigma_\ell \log R_\ell$, the variances added (`tools/whole_system.py`, `results/WHOLE_SYSTEM.md`; regrouped into places and routes by `docs/engine/export_whole.py`). A provider that ran Omni-Compass on its own back end would see that benefit on its own chips and racks; no tenant can meter it, so it is never claimed here as a measurement. No run has stacked the layers: each factor is one layer's own run with the layers under it native, and the product assumes a layer's ratio does not change when the layers around it also carry Omni-Compass (tested on the governors' four ways: 18 of 30 pairs agree within the noise). The stacked run that replaces the composition is preregistered (`docs/WHOLE_SYSTEM_PREREGISTRATION.md`).

Place	Measured so far (every interval carried, without the card's old run)
The software end: the cluster and the services on it (class L)	work **GAIN 26.6%**; speed **GAIN 304.8%**; machines **power given 42.5%**; energy **STEADY 0.0%**
The bare metal: the card and the machine	not in the headline scope: the machine's own layer is not yet run, and the card's own three runs are read on their own bill (`results/TWO_BILLS.md`)
The cloud's wire	it holds: the layer enters as exactly 1 on every gauge, its bill kept as native's

Route	Light	The whole workload against native (its index; the gauges correlated)	Gauge by gauge
On site: the software end × the bare metal	green, GAINING	**GAIN 43.4%** (+27.7% to +60.9%)	work **GAIN 26.6%**; speed **GAIN 304.8%**; machines **power given 42.5%**; energy **STEADY 0.0%**
Through the cloud: the software end × the cloud's wire × the bare metal at the back end	green, GAINING	**GAIN 43.4%** (+27.7% to +60.9%)	work **GAIN 26.6%**; speed **GAIN 304.8%**; machines **power given 42.5%**; energy **STEADY 0.0%**; bill **STEADY 0.0%**

By the index's rule (only what held the same way in all three of our runs enters) the same routes read **GAIN 43.5%** (+27.8% to +61.1%) on site and **GAIN 43.5%** (+27.8% to +61.1%) through the cloud. The bare metal

All patents, copyrights and trademarks filed in the USA.

enters both routes as no change until it is measured, so both routes today are the software end's and, through the cloud, the wire holding. Neither is a bill in money (section 76.8): a bill is the sum of the costs inside a declared boundary, and no figure is written for a place before its runs read it. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

60.7 A real database, a real message broker, a real cache

Five stacks whose knob is a resource an operator sizes once and leaves: the operator's fixed setting as native, the compass on that setting through the stack's own console as Omni-Compass on native, a tuning workload shown and not counted, and the untouched workloads judged; MySQL, MongoDB and Redis are also read with native exactly as the vendor ships it, where a factory setting already at the knob's top is at its limit on native and Omni-Compass watches. Every move on these knobs passes the brain's verdict first (section 45.4): a give-back or a spend is written only after its paired trial on the stack itself reads no LOSS, so a knob that cannot prove it pays stays at the operator's setting, and a table that reads STEADY on every row is the do-no-harm reading, not a missing one.

Written from the newest three-run table of each test by `python3 tools/results_chapter.py`, from the benefit sheet's record (`results/BENEFIT_SHEET.json`); `verify.py` fails a push where it differs. Each line names the test, its table and the engine its runs were on, its reading, and then every judged gauge with the span of the three runs' changes (the span of the three point estimates, not an interval), in the key's words. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

- **Redis, the cache's memory ceiling** (`results/live/V26_REDIS.md`, omni-v26): **GAIN, power given**, by the index's rule 4.9% LOSS. Work inside the line up 16% to 27% (GAIN); hit rate up 16% to 27% (GAIN); p95 cut 0% to 98% (GAIN); mean cut 40% to 77% (GAIN); host CPU busy cut 1% to 38% (GAIN); host CPU-seconds cut 0% to 39% (GAIN); CPU per 1,000 inside the line cut 22% to 51% (GAIN); process_cpu_seconds cut 7% to 15% (GAIN); memory ceiling held up 272% to 428% (power given); memory used up 250% to 411% (power given); p99 cut 0.6% to 1.6% (GAIN).
- **PostgreSQL, the pooler's pool size** (`results/live/V26_PGBENCH.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 1.8% LOSS. P95 up 0% to 11% (LOSS); mean up 0% to 172% (LOSS); connections most at once up 0% to 87% (power given); CPU per 1,000 inside the line up 0.0% to 1.0% (power given); work inside the line up 0.1% to 3.4% (GAIN); mean cut 0% to 30% (GAIN); connections held open up 18% to 34% (power given); host CPU busy up 0.4% to 3.0% (power given); host CPU-seconds up 0.4% to 2.8% (power given); p95 cut 2.4% to 8.0% (GAIN); p99 cut 0% to 72% (GAIN); median cut 0.1% to 1.2% (GAIN); host CPU busy cut 0.2% to 1.3% (GAIN); host CPU-seconds cut 0.2% to 1.3% (GAIN); CPU per 1,000 inside the line cut 0.3% to 1.4% (GAIN).
- **MySQL, the buffer pool's size** (`results/live/V26_SYSBENCH.md`, omni-v26): **GAIN, power given**, by the index's rule 12.5% LOSS. P95 cut 0% to 43% (GAIN); p99 cut 2% to 96% (GAIN); mean cut 1% to 77% (GAIN); host CPU busy cut 0.7% to 6.9% (GAIN); host CPU-seconds cut 0.6% to 6.8%

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(GAIN); CPU per 1,000 inside the line cut 1% to 25% (GAIN); pool held up 39% to 141% (power given); pages holding data up 42% to 111% (power given); work inside the line up 1% to 31% (GAIN).

- **MongoDB, the storage engine's cache size** (`results/live/V26_YCSB.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 7.1% LOSS. P99 up 0.2% to 4.5% (LOSS); cache size held up 0% to 178% (power given); cache in use up 0% to 167% (power given); process_cpu_seconds up 0.0% to 5.0% (power given); p95 up 0.9% to 1.6% (LOSS); host CPU busy up 3% to 15% (power given); host CPU-seconds up 4% to 16% (power given); CPU per 1,000 inside the line up 4% to 16% (power given); mean up 0.3% to 2.0% (LOSS); p95 cut 1.2% to 2.0% (GAIN); mean cut 1.4% to 2.2% (GAIN); host CPU busy cut 0.1% to 2.7% (GAIN); host CPU-seconds cut 0.3% to 3.2% (GAIN); CPU per 1,000 inside the line cut 0.2% to 3.4% (GAIN); process_cpu_seconds cut 1.5% to 1.9% (GAIN).
- **Kafka, the consumer group's size** (`results/live/V26_KAFKA.md`, omni-v26): **GAIN, power given**, by the index's rule 221.1% GAIN. Work inside the line up 16% to 23% (GAIN); p95 cut 99% to 100% (GAIN); p99 cut 92% to 100% (GAIN); median cut 0% to 30% (GAIN); mean cut 96% to 98% (GAIN); messages waiting, most cut 82% to 99% (GAIN); messages waiting, mean cut 96% to 98% (GAIN); CPU per 1,000 inside the line cut 2% to 14% (GAIN); consumers running up 73% to 215% (power given); consumers most at once up 150% to 300% (power given); host CPU busy up 2% to 14% (power given); host CPU-seconds up 2% to 15% (power given).

60.8 Robustness: the governor killed outright, the long run, its own cost

The robustness benchmark (`docs/ROBUSTNESS_PREREGISTRATION.md`) is a test of Omni-Compass itself, not of a gain: the governor killed outright inside the window, and a run of two hours. The governor's own processor is shown in every Kubernetes table, never judged.

Written from the newest three-run table of each test by `python3 tools/results_chapter.py`, from the benefit sheet's record (`results/BENEFIT_SHEET.json`); `verify.py` fails a push where it differs. Each line names the test, its table and the engine its runs were on, its reading, and then every judged gauge with the span of the three runs' changes (the span of the three point estimates, not an interval), in the key's words. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

- **Robustness: the two-hour run** (`results/live/V26_ROBUST_LONG.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 6.0% LOSS. Mean response cut 36% to 39% (GAIN); p95 cut 29% to 39% (GAIN); p99 cut 12% to 30% (GAIN); time over the line cut 29% to 35% (GAIN); failed requests cut 7.8% to 9.1% (GAIN); alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) cut 20% to 26% (GAIN); replicas up 20% to 59% (power given); pods started up 219% to 227% (power given); pod start wait, total (s) up 258% to 279% (LOSS); pod start wait, mean (s) up 4% to 22% (LOSS).
- **Robustness: the governor killed outright mid-run** (`results/live/V26_ROBUST_KILL.md`, omni-v26): **GAIN AND LOSS**, by the index's rule 1.7% LOSS. Mean response cut 28% to 40% (GAIN);

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

p95 cut 13% to 55% (GAIN); time over the line cut 31% to 35% (GAIN); failed requests cut 1.1% to 6.9% (GAIN); alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line) cut 19% to 22% (GAIN); replicas up 21% to 22% (power given); pods started up 102% to 159% (power given); pod start wait, total (s) up 104% to 181% (LOSS); robust: failed requests in the 300 s after the kill (%) up 3.9% to 9.0% (LOSS).

60.9 The modelled realms and the independent simulators

Every result here is evidence class S: a statement about a published model under its own native controller, never about hardware, and never counted in the Omni index. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

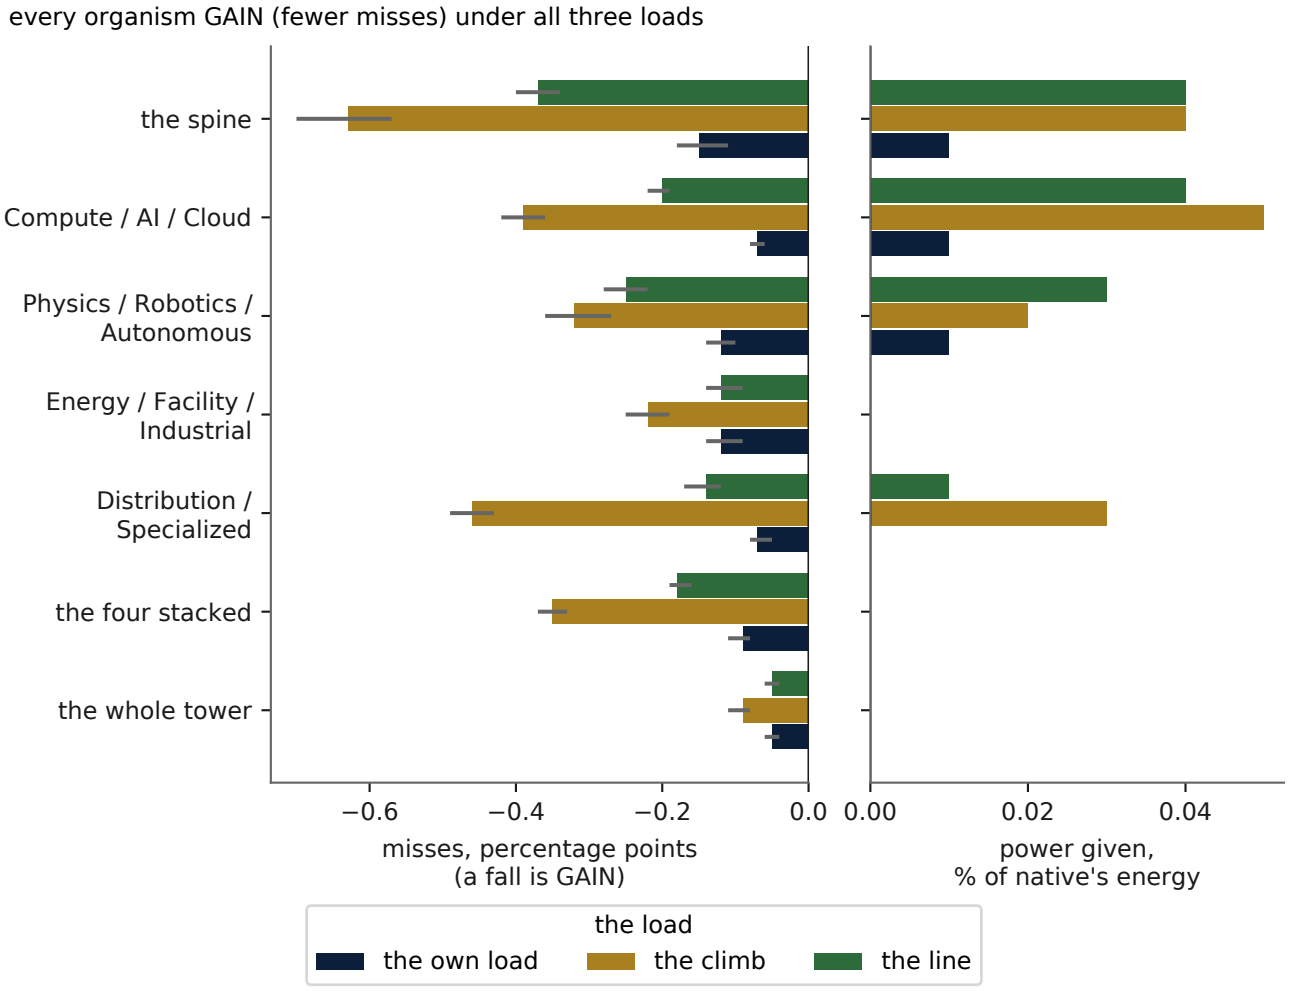

Figure 60. Receipt chart: the seven organisms under the three loads (the own load, the climb and the line), from results/realms_v5/REALMS_V5.md. Left, the change in misses in percentage points with its 95% interval, a fall read GAIN; right, the power given as a share of native's energy. Every organism reads GAIN (fewer misses) under all three loads; the organisms are class S, our own models.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The 1,107 muscles and the seven organisms (`results/realms_v5/REALMS_V5.md`). The newest record is engine omni-v8's: run 2026-10-17 15:39 UTC, commit `9819a903cba3`, preregistered seeds 3000 to 3009 (ten paired runs per muscle, per organism and per load), read again by the 0.5% rule on 24 October 2026. It runs again on the engine that stands; until its table lands, this one is omni-v8's.

Every muscle alone, under its own load and with work waiting in line	Muscles of 1,107
GAIN: fewer misses, faster or more work, and no LOSS under either load	**530**
of them: the waiting line cleared sooner	493
of them: over the line less often	445
of them: more work	12
STEADY, at its limit on native (native already runs the knob at the top of its range; Omni-Compass writes nothing)	421
STEADY, the same as native	156
LOSS, or GAIN and LOSS	**0**

Each organism under each load: the change in decisions over the line (Omni-Compass's count against native's), the largest change in work over the three loads, and the largest rise in energy (the organism's energy against native's; under the 0.5% floor it reads STEADY).

Organism (muscles)	Over the line: its own load	the climb	work waiting in line	Work, largest change	Energy, largest rise
The spine (267)	GAIN, down 6.1%	GAIN, down 7.9%	GAIN, down 8.8%	STEADY, 0.003% (under the 0.5% floor)	STEADY, up 0.039% (under the 0.5% floor)
Compute / AI / Cloud (540)	GAIN, down 3.6%	GAIN, down 7.0%	GAIN, down 8.3%	STEADY, 0.002% (under the 0.5% floor)	STEADY, up 0.046% (under the 0.5% floor)
Physics / Robotics / Autonomous (404)	GAIN, down 2.5%	GAIN, down 3.2%	GAIN, down 2.3%	STEADY, 0.002% (under the 0.5% floor)	STEADY, up 0.030% (under the 0.5% floor)
Energy / Facility / Industrial (480)	GAIN, down 7.5%	GAIN, down 2.7%	GAIN, down 8.3%	STEADY, 0.000% (under the 0.5% floor)	STEADY, the same
Distribution / Specialized (484)	GAIN, down 2.8%	GAIN, down 7.2%	GAIN, down 4.7%	STEADY, 0.003% (under the 0.5% floor)	STEADY, up 0.026% (under the 0.5% floor)

Organism (muscles)	Over the line: its own load	the climb	work waiting in line	Work, largest change	Energy, largest rise
The four stacked (1,908)	GAIN, down 3.6%	GAIN, down 4.8%	GAIN, down 4.3%	STEADY, 0.002% (under the 0.5% floor)	STEADY, the same
The whole tower (1,107)	GAIN, down 1.9%	GAIN, down 1.4%	GAIN, down 1.1%	STEADY, 0.000% (under the 0.5% floor)	STEADY, the same

Written from the newest three-run table of each test by `python3 tools/results_chapter.py`, from the benefit sheet's record (`results/BENEFIT_SHEET.json`); `verify.py` fails a push where it differs. Each line names the test, its table and the engine its runs were on, its reading, and then every judged gauge with the span of the three runs' changes (the span of the three point estimates, not an interval), in the key's words. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

- **Robot arms (MuJoCo), the three untouched robots** (`results/live/V26_MUJOCO.md`, omni-v26): **GAIN**, by the index's rule 3.8% GAIN. Energy per takt cut 0.8% (GAIN); copper heating per cycle cut 11% (GAIN); mechanical work per cycle cut 6.6% (GAIN); peak joint torque cut 29% (GAIN); tracking error, RMS cut 21% (GAIN); end-point error at the waypoints cut 11% (GAIN).
- **Power grids (SimBench), both load models** (`results/live/V26_PANDAPOWER.md`, omni-v26): **GAIN, power given**, by the index's rule 5.8% GAIN. Energy the loads drew cut 1.3% to 1.5% (GAIN); energy dissipated in lines and transformers cut 0.5% to 2.4% (GAIN); net import from the upstream grid cut 1% to 15% (GAIN); tap operations cut 16% to 38% (GAIN); energy dissipated in lines and transformers up 0.6% to 1.5% (power given); tap operations up 100% (power given).
- **Drone swarms, the three untouched cells** (`results/live/V26_SWARM.md`, omni-v26): **GAIN**, by the index's rule 2.2% GAIN. Energy per mission cut 5% to 17% (GAIN); fleet energy over the window cut 5% to 17% (GAIN); missions per charge at the autopilot's reserve up 5% to 21% (GAIN).
- **Buildings and batteries (CityLearn), the districts with batteries** (`results/live/V26_CITYLEARN.md`, omni-v26): **GAIN**, by the index's rule 1.4% GAIN. Electricity bought cut 3% to 14% (GAIN); daily peak draw cut 3% to 17% (GAIN); highest peak cut 2.7% to 4.4% (GAIN); ramping cut 3% to 10% (GAIN); daily load unevenness cut 0.9% to 6.0% (GAIN); monthly load unevenness cut 0.8% to 2.3% (GAIN); electricity bill cut 16% (GAIN); carbon cut 12% (GAIN); distance from zero net energy cut 1.0% (GAIN).

60.10 The ten organisms two ways: the twenty scenarios (modelled, class S)

The twenty scenarios (ten organisms, each native and with Omni-Compass on native; engine omni-v23, run 2026-10-31 20:06 UTC, three runs, seeds 3000 to 3002; `results/scenarios/SCENARIOS_20.md`). In the 9 modelled organisms the muscles over the line read GAIN in 9 (from GAIN, down 1.58% in the whole tower to GAIN, down 63.34% in the orchestra); the work STEADY in 9; the power STEADY in 7 (Compute / AI / Cloud: GAIN, a cut, down 0.59%; The orchestra: power given, up 52.38%). The whole organism without the card, composed from the real tables (class S, a composition of class P and class L measurements), reads GAIN 22.5% by the index's rule; its tables come from 5 engines (omni-v1, omni-v12, omni-v18, omni-v21, the engine of commit 5b2832f (4 October 2026)), so it is a composition across engines, never one engine's reading.

60.11 The one number, and the table

The one number. The Omni index over the real categories, judged across our three runs by the rule of 24 October, each test read from its own newest table with a reading (26 on omni-v26; no table is pooled across engines): **GAIN 20.0%** (real Kubernetes **GAIN 22.2%** over its 9 tests; the database behind its pooler **power given 1.8%**; real messaging **GAIN 221.1%**; the real cache **power given 4.9%**; the database's storage-engine cache **power given 7.1%**; the database's buffer pool **power given 12.5%**; each category weighed the same; Azure and the card join as their three-run tables land). The second reading, service alone (work and speed scored, machines and energy shown), stands at **GAIN 96.5%** (real Kubernetes GAIN 68.4%; the database behind its pooler GAIN 0.5%; real messaging GAIN 1524.3%; the real cache GAIN 93.7%; the database's storage-engine cache GAIN 0.04%; the database's buffer pool GAIN 7.9%). The benefit sheet reads the index's row GAIN AND LOSS. A category enters at whatever its tables show in all three of our runs, nothing included, which is the reader's guarantee that the number is not built from the categories that happened to work. The numbers of earlier engines are the road, in `docs/history`, and are never read beside these.

Every test's newest table in one place, written from the same record (`results/BENEFIT_SHEET.json`) by `python3 tools/results_chapter.py`; the gauges behind each reading, in the table's own words, are in `docs/BENEFIT_SHEET.md`.

Test	Class	Engine	Reading	By the index's rule	Table

The 945 modelled muscles as one tower, every muscle written at once	S	omni-v3	**GAIN**	0.3% GAIN	`results/realms/REALMS.md`

Running now and next. Every benchmark runs again on omni-v26, the engine that stands, released by the conductor (`scripts/dispatch_grid.py`, `scripts/reruns.txt`: A of every benchmark, then B, then C), the steady and wandering Kubernetes tests among them; Azure one run at a time in its region (the steady set, the bursts 1 4 1 6 1 9 and 1 6 1 8 1 6, the real day; A, B and C); the grid with the real cluster inside on GitHub's free runners. The runs of earlier engines already started run to their end and stand as their own engine's record. Google and Amazon are not yet run: their first sets, on omni-v10 on 18 October, stopped at the login at no cost, and since 24 October both queues are switched off and kept, wired as Azure's sets run (100 paired repetitions under the stopping rule, the 60 s beat, the $0 check first), each switched on by the founder's word (Google once its key is stored whole, Amazon once its account is on its Paid plan); the GPU chips wait for the founder's word; the CPU governor's measured run waits for a machine with a power meter.

60.12 Wire in, or watch: the verdict per knob

The founder's order of 9 October 2026 made a principle of what section 1.2 describes as a mechanism: Omni-Compass need not be wired into every muscle. Where it cannot beat the native controller on the muscle's own gauges, the muscle lives by itself and Omni only reads it, one wire out and no wire in. `tools/wiring_verdicts.py` applies that principle to every published result and prints the page `docs/WIRING_VERDICTS.md` (one row per knob and per muscle in `results/WIRING_VERDICTS.csv`; `verify.py` fails if the page differs from what the tables give). The rule is the same for every table: a knob reads **write** where at least one judged gauge is GAIN in all three of our runs and none is LOSS or power given in all three of our runs; **watch** where nothing is GAIN in all three of our runs, whether the rows are inside the noise, the runs disagree, or a gauge is LOSS or power given in all three of our runs with nothing against it (the LOSS is then named with its cause); and **operator's choice** where GAIN and LOSS (or power given) both hold in all three of our runs, a trade shown with both readings of the index. A modelled muscle takes its word from its realms label (`results/realms_v5`): a GAIN on work, speed or misses is write, the energy the max took for it power given and never a trade; SAME AS NATIVE and AT ITS LIMIT ON NATIVE are watch.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

What the page says today, quoted from it by `python3 tools/results_chapter.py` (`docs/WIRING_VERDICTS.md`, written by `tools/wiring_verdicts.py` from the tables that stand): "on the real stacks Omni earns its wire in on 0 of 26 knob-cases, trades on 22 and watches on 4. Of the 1,107 modelled muscles, 530 earn a wire in and 577 stay native: 421 of the 577 are at their limit on native (the knob already at the top of its range: nothing to push, read and left native) and 156 read the same as native (nothing moved beyond the noise). A knob left native costs nothing and earns nothing; it needs no wire in, and the page below says so muscle by muscle."

The same verdict, live (built 9 October, running since 10 October). The page judges after the fact; the founder's order is that the brain judge in real time, on the knob, before it writes. On the five live stacks that is now in the harnesses (section 45.4; `tools/knob_verdict.py` around the engine's own verdict, the engine unchanged): every knob starts in watch and is written only inside the allowance a paired trial on the stack itself has earned under the declared objective, one notch a trial; a refused step is not taken, a trial holds the knob, a fail-up never spends beyond the allowance, the operator's setting is always free. The amendments are declared in the five preregistrations with the expectation written before the runs (Redis left native under the resource objective, the first notch refused; Kafka allowed step by step while each consumer pays; PostgreSQL's add above the operator's setting refused on `simple_update`; MySQL's `read_write` chunks refused; MongoDB's cache given back a notch a trial). The runs were dispatched on 10 October, three a stack and objective, in the day's rerun of every benchmark on one commit (`docs/RERUN_2026-10-10.md`), and the tables, the index and the page are then read again from them.

60.13 The second set of 10 October

What the second set of 10 October taught the trial (the four rules written into Omni v4) is kept whole, with its numbers as they were read that day on that day's engine, in `docs/history/SECOND_SET_2026-10-10.md`; nothing of it is a result of the engine that stands.

60.14 Threats to validity, stated by us

A referee will look for the ways these results could mislead. We list the ones we know, what each would do to the numbers, and what the record does about it.

1. **The machines are shared.** Every Kubernetes, database, broker and cache run is on one GitHub runner with four cores, and the governor, the load generator, the probe and the system under test share it. A governor that costs CPU can slow the service it governs, and a noisy neighbour on the host can move a run. The pairing on one runner with rotated order removes the between-machine noise; the host's own busy share is recorded beside every run; the governor's own CPU is a gauge in every table and a loss in all three of our runs where it is one (the database, Kafka's light workload); and three separate runs on separate machines must agree before anything counts.
2. **kind is not a cloud.** Idle machines stay powered and native has no node autoscaler, so a machine given back on kind is a machine-hour in service, not a watt and not a dollar. The energy rows on kind are a

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

declared model and say so on every line. The bill is Azure's test, and its only result so far is inside the noise on a fleet too small to show one machine.

3. **Native is at its knee by design in the broker test.** The Kafka producer's peak offers nine tenths of the capacity measured for the operator's two consumers, so native's queue grows at the high steps and omni's does not. This is the situation the benchmark is of (a group sized for the quiet hours and overrun at the peak), it is preregistered, and it is why the latency ratios are large; the index page and the table say so. A native group sized for the peak would show a smaller latency gain and a smaller consumer cost, and would be a different, also legitimate, benchmark.
4. **Declared penalties.** The cache's 5 ms store trip on a miss and the broker's 1, 2 or 5 ms of CPU per message are declared parameters of our own application, not measurements of anyone's store. The gauges that depend on them (work inside the line, the request latency) scale with them; the hit rate, the lag, the consumers and the memory held do not.
5. **Simulators are models.** Every S result is a statement about a published model under its own controller. A model may flatter or punish the governor in ways the real plant would not. S results are therefore shown beside the index and never inside it, and the muscles' models are the simplest physics that reproduces the meter's response to the knob, with the native controllers tuned as their authors ship them.
6. **The tuning case was seen.** Every benchmark's rules were set on one tuning case, and that case is shown and not counted. Where a rule changed after a counted result was seen (the swarm table's reproduction tolerance), the amendment is written in the preregistration with its time and reason, the table says so, and the runs were not rerun.
7. **The engine changed, version after version.** Each version is a fingerprint (`tools/omni_version.py`), every result is labelled with its engine, and the tools refuse to mix engines; a reader comparing two engines' numbers is comparing two engines. The one composition across engines, the whole organism (section 60.10), names its engines and says so.
8. **Three runs are three, not thirty.** The three-run rule is a replication standard, not a large sample. A row the same in all three of our runs of ten pairs is a row whose paired difference cleared zero in each of three independent samples of ten; the intervals are shown so a reader can judge their width. Where the intervals are wide, the manual says the test lacked power rather than calling the result a null.
9. **The founder's own harness.** The application in front of the cache, the producer in front of the broker, the load generator and the probe are ours. They are declared, versioned, archived with every run and reproducible from the repository; they are not independent of us. The independent pieces are the systems under test, their native controllers, the simulators and their shipped controllers, and the benchmark tools (pgbench, kind, Kubernetes, PyBullet, MuJoCo, pandapower, CityLearn) that others wrote. The load schedules of the Kubernetes tests were ours too, written one step at a time; the public-trace test (`docs/TRACES_PREREGISTRATION.md`) answers that by replaying a day of demand somebody else measured (the Google cluster trace of 2011, then the Azure Functions trace) under the wandering test's own rules, the derivation receipted and committed before the runs; its newest table is section 60.1's line for it, every row with its word, its LOSS row included.

All patents, copyrights and trademarks filed in the USA.

60.15 What is not yet shown, and the open program

What this manual does not show, and the program that will show it or show its absence:

- **A bill saving.** Azure's steady set on omni-v18 read the bill inside the noise and counted no work (section 60.5); on the bare metal the A10's work for each dollar reads the runs disagree (`results/TWO_BILLS.md`). No bill saving is shown; the sets that count the work run next, and a set that reads STEADY on a fleet that could have seen a saving is that result.
- **The card at scale.** An A100 (omni-v21) and an A10 (omni-v23) have three-run tables of their own (section 60.6, `results/gpu/`); the eight-card box and the organisms on the card are the next runs, each at one named commit.
- **Robustness over a day.** The governor killed outright and the two-hour run are measured (section 60.8); the 24-hour run on rented machines (`docs/ROBUSTNESS_PREREGISTRATION.md`, scenario 2b) has no table yet, and the same test on the other stacks remains open.
- **A demand shape that is not ours, on more than one trace.** One public trace is read (a day of the Google cluster trace of 2011, section 60.1); the Azure Functions invocation trace, a request-driven shape, has no table yet, and the "our own schedules" threat of section 60.14 is answered in full only when a second, differently shaped day is read.

The queue beyond these, in order, is `docs/REGISTER.md` section 4, one or two at a time, each preregistered before it runs: PX4 and ArduPilot swarms, YCSB and HammerDB, Spark, OpenSearch, fio, Open-RMF, Basilisk, Orekit and GMAT, RocketPy and OpenRocket, Cantera. When the founder declares the engine final, the engine that stands then is published as Omni-Compass 1.0, and the older fingerprints go to `docs/history` as the road to it.

CHAPTER 61

Wire In, or Watch: The Verdict per Knob

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

How to read this receipt. Every judged row reads one of three words, decided by what its gauge is for and never by the plus or minus sign of its number. **GAIN**: the gauge moved toward its declared aim against native (more work done, a shorter wait, fewer misses or failures, or a resource cut). **STEADY**: native and Omni-Compass within 0.5% of each other (the mean of the three runs' changes under the 0.5% floor, or no change at all), or the knob is at its limit on native. **LOSS**: the gauge moved away from its aim (less work done, a longer wait, more misses or failures). A resource spent or held (energy, the power drawn and its peaks and

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

swings, machines, memory, processor time, a bill, wear) that fell is a cut, a GAIN; one that rose is **power given**, what Omni-Compass put in to buy the work and the speed shown beside it, always shown and never called a loss; work bought with each unit of a resource (work per energy) that fell is power given too. So a minus can read GAIN (a response time cut) and a plus can read LOSS (failed requests up). A change of 0.5% or more, the mean of the three runs' changes, reads GAIN, LOSS or power given: **in all three of our runs** where A, B and C moved the same way with every interval clear of zero, otherwise **by the mean of our three runs**, with the count of runs beyond the noise beside it; **the runs disagree** names runs that moved 0.5% or more in opposite directions, a test unstable there; **shown, not judged** is a gauge declared shown only. The output follows the input: every reading is the result of the tune, the wiring and the load it names, and where a reading elsewhere differs the first presumption is the wiring (`DISCLOSURES.md`, section 4). The full key, letter by letter: `docs/HOW_TO_READ_THE_RESULTS.md`. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

Omni-Compass is wired **out of** every muscle: it reads every reading. It is wired **into** a knob only where the paired measurement shows no gauge of the muscle read **LOSS** against native. Where the measurement shows nothing (**STEADY**), or shows a LOSS, the muscle stays native and Omni only watches it: one wire out, no wire in. This is not a new rule. It is what the engine does on the muscle itself before it moves anything (`omnicompass/verdict.py`: the paired trial, and the verdict **left native** where no step is allowed), and it is the watch arm of every realms run (`docs/REALMS_PREREGISTRATION.md`: the governor reads every period and writes nothing). This page applies the same principle to every published result, one verdict per knob, so that an operator can see which knobs earn a wire in and which stay native. The founder's order of 9 October 2026: where Omni cannot beat native, the muscle lives by itself; we only wire out of it.

Every verdict here is computed by `tools/wiring_verdicts.py` from the test's own result file; nothing is typed in, and `verify.py` fails if this page differs from what the tables give. One row per knob and case: `results/WIRING_VERDICTS.csv` (1214 rows, the 1,107 modelled muscles included one by one, and the seven organisms under three loads).

61.1 The rule

Every judged gauge of a table counts (rows marked "shown, not judged" never do). Every reading is **GAIN**, **STEADY** or **LOSS**, decided by what the gauge is for and never by the sign of its number (the key: `docs/HOW_TO_READ_THE_RESULTS.md`): response times and failed requests are time waited, missed or failed, so a fall is GAIN; work done is GAIN when it rises; machines, energy, memory, connections, consumers and processor time are resources spent, so a fall is a cut, a GAIN, and a rise is **power given**, the price named beside what it bought. Each gauge's aim is its preregistration's; an operator whose aim differs reads the same numbers the other way. A knob reads:

- **write**: at least one gauge GAIN across our three runs, and no LOSS and no power given. Omni holds the knob.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **watch**: no GAIN across our three runs. The knob stays native; Omni reads it and writes nothing. Where a gauge read LOSS or power given across our three runs, it is named and its cause given below. Where the runs disagree, nothing is settled and the knob stays native until it is.
- **operator's choice**: GAIN, and LOSS or power given, both judged across our three runs: a trade. Both readings of the Omni index are shown where the test is in it (the resource reading, the preregistered headline, and the service reading, work and speed alone), and the side that pays is named. The operator who wants the gain and can pay the price wires in; every other operator watches.

A modelled muscle (the 1,107 on their plants under its own load and work waiting in line, `results/realms_v5/MUSCLES_V5.csv`, the max of `realms/compass_arm_v5.py`, run on omni-v8: `results/realms_v5/REALMS_V5.md`) takes its verdict from its label by rule: a GAIN on work, speed or misses (MORE WORK, FASTER, FEWER MISSES, alone or together, on every load it ran) is write, and the energy the max took for it is power given, shown beside it and never a trade (the founder's order of 13 October); SAME AS NATIVE is watch, nothing moved beyond the noise; AT ITS LIMIT ON NATIVE is watch by design, the knob already at the top of its range on native, read and left native.

61.2 The count

Where	Knobs or cases	Write	Operator's choice	Watch
Real stacks, three runs each (Kubernetes under seven demands; the pool, the consumer group, the memory ceiling, the storage-engine cache and the buffer pool, each under its untouched workloads)	26	0	22	4
Independent simulators, three runs each (robot arms, grids, districts, swarms; evidence class S)	38	21	14	3
The 1,107 modelled muscles, alone on their plants under two loads (evidence class S)	1107	530	0	577
The organisms with the real cluster inside (GitHub at 10 and 100 copies; Azure at 1,000)	14	12	1	1

In words: on the real stacks Omni earns its wire in on 0 of 26 knob-cases, trades on 22 and watches on 4. Of the 1,107 modelled muscles, 530 earn a wire in and 577 stay native: 421 of the 577 are at their limit on native (the knob already at the top of its range: nothing to push, read and left native) and 156 read the same as native (nothing moved beyond the noise). A knob left native costs nothing and earns nothing; it needs no wire in, and the page below says so muscle by muscle.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

61.3 The real stacks (evidence class L: live software, three separate GitHub runs on the frozen engine)

The reading of every judged gauge is in the test's own table (the Source column). The index columns are the two readings of `results/OMNI_INDEX.md` for that test, where it has one.

61.3.1 Real Kubernetes: one knob under seven demands

The knob: the autoscaler's replicas, the floor and the machines, on top of the Horizontal Pod Autoscaler (kind clusters on GitHub, ten pairs a run).

Demand	GAIN across our three runs	LOSS or power given across our three runs	Verdict	Index: resource	Index: service	Why	Source

Workload	GAIN across our three runs	LOSS or power given across our three runs	Verdict	Index: resource	Index: service	Why	Source
	41%, host CPU busy cut 1% to 14%, host CPU-seconds cut 0% to 14%, CPU per 1,000 inside the line cut 22% to 32%, process_cpu_seconds cut 7% to 12%					389% (power given), because the knob itself: the ceiling grows while the cache is full and misses, so a wide working set is held instead of evicted; the memory is the price of the hit rate, declared in advance as the gauge expected to rise: the power given (`docs/REDIS_PREREGISTRATION.md`, the gauges); memory used up 324% to 325% (power given), because the memory actually used follows the ceiling: the working set the operator's 64 MB could not hold is held. The trade pays under the service reading (GAIN 12.9%)

61.4 Every LOSS and every power given across our three runs on a real stack, and why

The founder's question was where the negatives are and why each is there. Every gauge that read LOSS or power given in all three of our runs on a real stack, with its cause read from the preregistration that carries the result:

- **Kubernetes, replicas: steady work up 3.2% to 4.7%, demand that wanders up 24% to 31%, all four at once up 5% to 15%, a noisy neighbour up 2.0% to 4.0%, faults up 26% to 30%, a queue of jobs up 1% to 25%, a public day of demand (Google 2011) up 14% to 26%, With its add-ons: KEDA on the CPU target and the live requests in flight, Omni-Compass on top, ten pairs, three runs up 22% to 31%, power given** (15.1 / 2.013 / 8.526 / 8.532 / 8.886 / 9.469 / 9.483 / 9.652 → 10.74 to 8.802 in run A). See the table. Verdict: **operator's choice** on every workload named.
- **Kubernetes, pod start wait, total (s): demand that wanders up 108% to 133%, all four at once up 107% to 167%, a noisy neighbour up 10% to 23%, faults up 67% to 92%, a queue of jobs up 129% to 1700%, a public day of demand (Google 2011) up 163% to 173%, With its add-ons: KEDA on**

- **MongoDB, p95: burst up 0.9% to 1.6%, LOSS** (0.3517 → 0.3547 in run A). See the table. Verdict: **watch**.
- **MongoDB, host CPU busy: burst up 4% to 10%, c up 3% to 15%, power given** (0.07632 / 0.1753 → 0.08741 to 0.1823 in run A). See the table. Verdict: **watch** on every workload named.
- **MongoDB, host CPU-seconds: burst up 5% to 13%, c up 4% to 16%, power given** (127.2 / 138.2 → 133.2 to 160.1 in run A). See the table. Verdict: **watch** on every workload named.
- **MongoDB, CPU per 1,000 inside the line: burst up 5% to 13%, c up 4% to 16%, power given** (0.1032 / 0.2387 → 0.1195 to 0.2498 in run A). See the table. Verdict: **watch** on every workload named.
- **MongoDB, mean: c cut 0.3% to 2.0%, LOSS** (0.05854 → 0.05973 in run A). See the table. Verdict: **watch**.
- **MySQL, pool held: burst up 39% to 62%, read_only up 59% to 131%, read_write up 95% to 126%, update_index up 136% to 141%, power given** (512 → 1156 to 827.2 in run A). See the table. Verdict: **operator's choice** on every workload named.
- **MySQL, pages holding data: burst up 42% to 62%, read_only up 58% to 106%, read_write up 92% to 111%, update_index up 94% to 95%, power given** (457.4 / 457.6 / 462.2 / 464 → 720.6 to 977 in run A). See the table. Verdict: **operator's choice** on every workload named.

12 of these are a LOSS (alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line), mean, p95, p99, pod start wait, mean (s), pod start wait, total (s), queue finished, second app: failed requests (%), second app: response time (ms), 95th percentile): each is named above with its cause, and each is a fault to find and fix, our own wiring first. The rest are power given, a resource spent to buy the service the knob exists for. Where the resource was given and nothing was bought (PostgreSQL's `simple_update`), the verdict is watch; where it bought service, the verdict is the operator's, and both index readings say what the trade is worth.

61.5 The independent simulators (evidence class S: deterministic models with their own native controllers)

61.5.1 Robot arms (MuJoCo Menagerie, Google DeepMind)

The knob: the servo's speed override inside the takt.

Case	GAIN across our three runs	LOSS or power given across our three runs	Verdict	Why	Source
kinova_gen3	energy per takt cut 0.8%, copper heating per cycle cut 11%, mechanical work per cycle cut 6.6%, peak joint torque cut 29%,	none	**write**	No LOSS: the same job inside the same takt, hit more accurately with less force; the cycle is slower inside the takt (shown, not	`results/live/V7_MUJOCO.md`

Why the line heating rose on four grids (power given). The lower setpoint carries the grid's power at a lower voltage and therefore a higher current, and the energy dissipated in the lines rises with the square of the current. The four grids where it rose are four of the five that export more than they import (net import negative: rural 1 and 2, semiurb 1 and 2); on the importing grids the loads' own draw falls with the voltage under ZIP loads and the line heating falls with it. Under constant-power loads the loads draw the same at any voltage, so the setpoint saves nothing on the loads and the exporting grids give the line heating with nothing bought. Tap operations, declared in advance as Omni's expected cost (`docs/PANDAPOWER_PREREGISTRATION.md`): this grid barely taps on its own (4 a year), so Omni's moves double a very small count. The verdict on those four grids is the operator's: the loads' energy and the upstream import cut (GAIN) against the lines' heating up (power given); under constant-power loads on 1-MV-rural--1-sw, where nothing was bought, it is watch.

				no)	
quebec_neighborhood_without_demand_response_set_points			**no knob**	no electric battery in the district (20 buildings, 0 water tanks left native): there is nothing for Omni to hold, so there is nothing to decide; any difference between the arms is CityLearn's own run-to-run variation (scores that differ in A, raw: time uncomfortable -0.28%; reproduced: no)	`results/live/V7_CITYLEARN.md`

Why the ramping (power given) and the energy not served (LOSS) rose in the 2023 districts, and the bill moved under the floor (STEADY). The seven 2023 challenge districts are small (3 to 6 buildings) and short (720 to 2,208 hours), and in them the energy not served and the comfort rows move, where in the county neighbourhoods they read the same: the compass steers the batteries from the district's electricity reading alone (one wire, one muscle, `docs/CITYLEARN_PREREGISTRATION.md`), flattening the draw it sees, and in these districts that leaves less in the batteries for the hours that count against the bill, the hour-to-hour ramping and the energy not served. The bill, what the battery is bought to lower, is up 0.19% to 0.35% in all three of our runs here, under the 0.5% floor (STEADY, under the floor): the battery buys nothing on the bill there, so for the operator who pays the bill this is a watch. The cause is a reading of the tables, not yet tested on its own.

61.5.4 Drone swarms (gym-pybullet-drones, University of Toronto)

The knob: the autopilot's cruise override.

61.6.3 Why the watch muscles are watch

- **421 muscles are at their limit on native.** Native already runs the knob at the top of its range: every admission knob lets everything in while change is permitted (275 admission knobs), a power knob runs the full clock or the full battery power (96 power knobs), and 50 capacity and setpoint knobs sit where native's own controller already has what the plant needs. There is nothing for the max to push; the knob is read and left native, STEADY by design, and no wire in is needed.
- **156 muscles read the same as native**: 37 of them wrote and nothing moved beyond the noise on work, speed or misses, 119 wrote nothing because native held the reading and the law had nothing to push. Watch, by rule; these are the room the next engine looks for a gain in, in the model gate first.

61.6.4 Power given, muscle by muscle

All patents, copyrights and trademarks filed in the USA.

The max buys work and speed; the energy it takes is **power given**, shown beside what it bought and never a trade or a loss (the founder's order of 13 October). The write muscles whose power given on their own load is the largest:

Muscle	Family	Knob	Reading	Misses (percentage points)	Work	Power given: the energy
db_replicas	Database & Transactions	capacity	GAIN (fewer misses)	down 5.54	up 0.27%	up 104.31%
io_capacity	Database & Transactions	capacity	GAIN (fewer misses)	down 6.89	up 0.35%	up 96.73%
read_route	Database & Transactions	capacity	GAIN (fewer misses)	down 6.31	up 0.35%	up 90.41%
synchronous_replication	Database & Transactions	capacity	GAIN (fewer misses)	down 3.90	up 0.39%	up 89.14%

An organism's label is the whole's: every muscle written at once. The wiring an operator takes from this page is finer: the write muscles wired in, the watch muscles left native with one wire out. The organism result says the whole, written at once, read GAIN (fewer misses) in every organism under every load; the work and the energy beside it moved under the 0.5% floor in every one (the work at most 0.003%, the energy at most 0.046%), STEADY; this page says which parts carried it.

61.7.2 The organisms with the real cluster inside

The knob is the cluster's (the autoscaler's replicas, the floor and the machines), under the organism's own demand, with the modelled muscles around it. The cluster's gauges decide the verdict; the organism's modelled work and energy are shown beside them and are judged muscle by muscle above.

61.8 Not decided here

- **Azure's managed Kubernetes (the bill):** the two tables on Omni v1 (`results/live/V1_AKS_STEADY.md`, `V1_AKS_BURST.md`) ran a 4-worker fleet, where every gauge read STEADY, no difference beyond the noise, but the burst's p99 in one run; the steady set of 100 paired repetitions on omni-v18 (`results/live/AKS_STEADY_100_OMNI_V18.md`) read the compute bill up 1.2% by the mean of its 97 pairs, its interval across zero (power given, not beyond the noise), and the 99th percentile GAIN (down 11.0%). Until a set reads the bill beyond the noise the verdict on Azure is watch, for want of a result rather than because of one.
- **The card (NVIDIA, its own meter):** the card runs on rented cards are read in their own three-run tables (`results/gpu/`, omni-v21 and omni-v23), not on this page; every card result before them is obsolete.
- **The robustness runs** (the governor killed mid-run, the long run): read in their own tables (`results/live/V21_ROBUST_KILL.md`, `results/live/V21_ROBUST_LONG.md`); they test the governor's own staying power, not a knob's value.

61.9 What this means for the wiring

The two-way plug stays one wire in and one wire out (`docs/WIRING_GUIDE.md`). This page decides, per knob, whether the wire in is connected. A knob marked **write** is wired both ways. A knob marked **watch** is wired out only: Omni reads it, learns from it, and never writes it; the native controller lives by itself. A knob marked **operator's choice** is wired out, and in only by the operator who wants that trade. The engine's verdict (`omnicompass/verdict.py`) does the same on the muscle itself at run time, and a knob it has left native is a watch knob whatever this page says. Nothing on this page changes the engine (the one that stands is named by `tools/omni_version.py`); it changes what an operator connects.

61.10 The same verdict, live: the brain decides on the knob before it writes

This page judges after the fact, from published tables. The founder's order of 9 October is that the brain judge in real time, on the knob, before it writes, and that a knob which cannot prove it pays stay native. On the five live stacks (the pool, the consumer group, the memory ceiling, the storage-engine cache, the buffer pool) that is now built into the harnesses: `tools/knob_verdict.py` wraps the frozen engine's own verdict (`omnicompass/verdict.py`, unchanged) around every live knob. The knob starts in watch; a paired trial on the stack itself (the knob held at the deepest step already allowed, then one notch further, under the same traffic) allows one notch at a time under the declared objective, the resource reading of the index by default or the service reading at the operator's choice; a refused step is not taken and not retried for a minute; a trial holds the knob; a fail-up never spends beyond the allowance; the operator's setting is always free. The audit carries the cost sample and the verdict's state every second, the arm record sums it, and the three-run tables print the verdict per workload. It is declared as an amendment in each of the five preregistrations with the expectation written before the runs (Redis: left native under the resource objective; Kafka: allowed step by step while each consumer pays; PostgreSQL: the add above the operator's setting refused on `simple_update`; MySQL: the `read_write` chunks refused; MongoDB: the cache given back a notch a trial). The runs on it were dispatched on 10 October 2026 (`docs/RERUN_2026-10-10.md`); this page is then read again from their tables. Inside the modelled realms every muscle carries its own card since omni-v5 (`realms/muscle_cards_v5.csv`, `docs/FORMAL_V5.md` section 5); the trade between muscles judged on the whole organism is the next version's work.

Where the brain's verdict stood when this table was written (the live wires on Omni v3), knob by knob. Every wire in this table is now in the fingerprint of the engine that stands, omni-v26 (`OMNI_V26.json`: `tools/knob_verdict.py`, `tools/store_brain.py`, the five store runners, the card's `omni_controller/gpu_compass.py`, the robot, swarm, building, grid and processor runners), and omni-v22 brought the five store wires to the max: what a wire's own rule asks goes through unclamped, up to the operator's cover, never below native (`docs/OMNI_V22.md`). Who decided, in real time, whether a knob pays before it is written, and in which directions (spend: more resource for service; give back: less resource where the service holds):

Where	The knob	Who decides it pays, and when	Directions tried	Engine
The 1,107 modelled muscles	each muscle's knob	the max on every muscle, every muscle its own card; the knobs native already runs at the top of their range read and left native	the law's own push and pull	the max (`docs/OMNI_V5.md`), its table run on omni-v8 (`results/realms_v5/REALMS_V5.md`)
The machine itself: the Linux kernel's frequency ceiling (`docs/CPU_POWER_PREREGISTRATION.md`)	one knob	`tools/knob_verdict.py` around the engine's verdict: every notch down tried on the machine first, under the index's reading for one machine (energy x latency / work) or energy per request inside the line	give back only (the ceiling cannot go above the top; the top always free)	outside the engine; built 10 October, waiting for a machine on the metal, no run yet

CHAPTER 62

The Pilot Protocol and Kit

62.1 Pilot Protocol

> **Before you wire anything:** read `DISCLOSURES.md`. Omni-Compass acts only through the wires it is given; it cannot be slapped on. If your paired receipts differ from the published benchmarks in direction, the first presumption is wiring: check the installation with section 42.5 of the manual (*Wired right or wired wrong*).

A pilot is the one proof our own runs cannot give: Omni-Compass on top of the licensee's own native controllers, on the licensee's own systems and work, read against native by the licensee's own engineers. Every result Dubra Software Inc. / The Omni-Compass LLC publishes was run and scored by its own code, and every table says that no outside party has reviewed or approved it. A pilot run by this protocol is how that

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

changes. The protocol was rewritten on 31 October 2026 for the engine that stands: native stays on in every arm, Omni-Compass moves native's knobs and never replaces native, and the readings are the receipts and the service gauges, read by the one key.

62.1.1 Before day one: the agreement and the license

- The evaluation license covers evaluation and simulation: test and staging systems, the models and `verify.py`.
- Governing live, customer-facing traffic is production use, and production use needs the signed, paid Omni-Compass Enterprise License first.
- A pilot on a production system, the read-only shadow included, runs only under a pilot agreement signed with The Omni-Compass LLC before day one. The agreement names the systems, the dates, the rules on this page and who receives the readings.

62.1.2 What runs, and what does not

- **The governor** (`omni_controller/controller.py`; on a graphics card, `omni_controller/gpu_governor.py`) sits on top of the native controllers already there: Kubernetes' pod autoscaler and cluster autoscaler, the card's own power management. Native stays on in both arms. Omni-Compass sets native's knobs (the autoscaler's target and range, the machines in service, the CPU limits, the card's power limit) and never takes native's place.
- **The engine at its factory tune**, as shipped (`docs/FACTORY_PROFILE.md`), at the factory beat. Any knob may be turned. A changed tune's readings are its own, and turning a knob can change every metric in either direction (`DISCLOSURES.md`, section 3).
- **Not the pilot:** the C++ engine and `verify.py`. They check that the engine's two copies compute the same and that the code does what its rules say (phase 0). They govern nothing.
- **Omni-Compass by itself** (the third arm: native's autoscalers off, Omni-Compass the only controller on those knobs) runs only where the licensee chooses it, after phase 2, preregistered as `docs/SOLO_PREREGISTRATION.md` is.

62.1.3 Phase 0: the code checked (one day, the evaluator's own machine)

Run `python3 verify.py`. Pass: `VERIFICATION: PASS`. This includes the parity tests of the C++ engine against the Python (`tests/test_cpp_*_parity.py`), the shield's invariants and the reading rules. `python3 tools/reproduce.py` rebuilds every published table from its archived raw runs and exits 1 on any difference.

62.1.4 Phase 1: shadow (one week, no write rights)

- The shadow kit (`docs/PILOT_KIT.md`, `scripts/pilot_shadow.sh`): the governor in observe mode at the factory beat, under an identity that can read and cannot write. The kit proves this with `kubectl auth can-i` and stops if any write right exists.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- Logged at every decision: what Omni-Compass would set, what native did and what followed (`shadow_out/audit.jsonl`), with the count of writes, which must be 0.
- Pass, agreed before the start: no write, and no logged decision that breaks the shield's invariants I1 to I5 (claim C7, `docs/CLAIMS_REGISTER.md`).

62.1.5 The handover (one day)

One muscle at a time, in this order: the power cap, the machines in service, the pod autoscaler's target and range, then the CPU limits. `--native MUSCLE[,...]` leaves every muscle not yet handed over where native runs it. At each handover the reset is tested: everything goes back to native, and the native settings are read back equal to the snapshot taken at the start.

62.1.6 Phase 2: the paired pilot (30 days: three runs of 10 days, A, B and C)

- **The pairing:** two matched pools at the same time, the same work split between them: native alone on one, Omni-Compass on top of native on the other. Where one pool is all there is, alternate whole days between the arms, with the same days of the week in each.
- **The three runs:** days 1 to 10 are run A, days 11 to 20 run B, days 21 to 30 run C. Each run is read on its own, and the three are read together by the three-run rule (`tools/confirm_abc.py`).
- **The stops:** the kill switch is tested on the first day and the last. It is instant, for security only, and puts every setting back to native (`omnicompass/master.py`, `tools/omni_switch.py`). The lease is tested once: stop the governor's process and watch the plug walk every setting back to native gradually.
- **Pass:** the pilot holds. Nothing the service is judged on reads LOSS against native in run A, B or C by the one key, and every resource that rose is read beside the work it bought, as power given.

62.1.7 What to read: the receipts and the service gauges

Where	The receipt, native against Omni-Compass	Read from
Through the cloud	the work per dollar: the work completed over the provider's bill for each arm's machines	the provider's own cost export and the licensee's request or job counts
The chip	the work per joule: the work completed over the card's own energy counter, with its clocks, temperature and throttle reasons beside it	the card's published interface (`nvidia-smi`, NVML)
On site	the work per machine-hour: the pool is the owner's, so its hours are no bill	the capture below

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Where	The receipt, native against Omni-Compass	Read from
The service, every place	the 95th percentile response time (the 90th and 99th beside it), the minutes over the response line, the pods waiting for a place, the failed requests, the work completed	the licensee's own monitoring
Oversight, every place	the alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line: the minutes an on-call page would be open), and the operations engineer-hours where the licensee logs them, each turned into dollars only at the licensee's own rates	the alert history and the licensee's own time records
Omni-Compass itself	every write it made, read back, and every reason	its audit (`--audit`)

Capture both arms read-only with `fleet/capture/kube_capture.sh`, then score each run:

```
python3 pilot/score.py --baseline native.csv --omni omni.csv [--idle-w W --dyn-w W]
```

It reports node-hours and energy per used CPU core-hour, utilisation, pending-pod minutes and the autoscaler's shortfall minutes, each with a bootstrap 95% interval over hourly blocks. Energy is measured only where the capture holds a meter's `power_w`; where no meter reads it, energy is not scored. Each run needs at least 24 hourly blocks per arm (a 10-day run holds about 240).

62.1.8 The paired audit sheet

One sheet a run, filled in only from that run's own records, both columns measured, nothing written before the run and every LOSS row kept. The licensee's own engineers fill it in; the one key reads it across the three runs.

```
OMNI-COMPASS PAIRED AUDIT — native against Omni-Compass on native
Window: ____ days     Place: bare metal / through the cloud     Engine
    ↪ : omni-v__ (fingerprint ________)
Run: A / B / C  (each run paired; the same work offered to both arms)

                                              NATIVE          OMNI-COMPASS
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    ↳ ON NATIVE
WORK      Work completed (requests/jobs) __________     __________
BILL      Machine-hours billed           __________     __________
          Rate per machine-hour ($)      __________     __________
    ↳ (the same rate in both)
          Other metered line items ($)   __________     __________

          Bill, B ($)                    __________     __________
FOR THE   E = W / B (work per dollar)    __________     __________
BILL      G = E(Omni) / E(native) − 1    ____________   read across th
    ↳ e three runs: GAIN, STEADY or LOSS
OVERSIGHT Alert minutes (p95 over line)  __________     __________
          Operations engineer-hours      __________     __________

    ↳ (the licensee's own logs)
          Labor at the licensee's rate   __________     __________
HEALTH    Failed requests                __________     __________
          95th-percentile response (ms)  __________     __________
```

On bare metal the bill is fixed for the window, so a benefit shows as more work inside it (W); through the cloud it may show as more work, a smaller bill (B), or both. Either way it is read in G, the one equation of `results/TWO_BILLS.md`. The labor line is the licensee's: the record of this repository counts alert minutes and the governor's own commands, never people, and no rate or share is assumed for it.

62.1.9 Reading it

Every gauge is read by the one key (`tools/readings.py`, `docs/HOW_TO_READ_THE_RESULTS.md`): GAIN, STEADY or LOSS by what the gauge is for, never by the sign of its number. Time waited, missed or failed that fell is a GAIN; work that rose is a GAIN; a resource spent or held that fell is a cut, a GAIN, and one that rose is power given, never a LOSS. A mean change under 0.5% reads STEADY. Across the three runs a reading is GAIN or LOSS in all three when every run moved the same way clear of zero; the runs disagree when clear runs moved in opposite directions, and that is a finding to look into, not a result.

62.1.10 Reporting

Every row is reported, LOSS included, in the key's words, with the run it came from. The readings, the captures and their SHA-256 sums go to the licensee and to Dubra Software Inc. / The Omni-Compass LLC as the pilot agreement says. Where the pilot's direction differs from the published benchmarks, the first presumption is the wiring (section 42.5 of the manual), and the pilot goes on once the wiring is checked.

All patents, copyrights and trademarks filed in the USA.

62.2 Omni-Compass shadow pilot kit

What a customer runs first. Omni-Compass watches the cluster read-only beside its own autoscalers. At the engine's factory beat (every 60 s; `OMNI_INTERVAL` sets another) it decides what it would do, using the same closure law that was benchmarked. It never writes.

1. `kubectl config use-context <the cluster>`
2. `DURATION=86400 IDLE_W=<watts per idle node> DYN_W=<watts at full load> bash scripts/pilot_shadow.sh`
   - It proves with `kubectl auth can-i` that the identity can read and cannot write, and stops if any write permission exists.
   - It captures telemetry and logs every recommendation to `shadow_out/audit.jsonl`.
   - It writes `shadow_out/SHADOW_REPORT.md`: node-hours used against node-hours Omni-Compass would have used, and the write count, which must be 0.
3. Scoring against a matched baseline: `python pilot/score.py --baseline baseline.csv --omni omni.csv` (bootstrap intervals over hourly blocks).

Guarded control follows `docs/PILOT_PROTOCOL.md`: one loop at a time, the reset tested at each handover.

The kit is exercised end to end on kind by the `live-shadow` workflow.

CHAPTER 63

The GPU Bench

Before you wire anything: read `DISCLOSURES.md`. Omni-Compass acts only through the wires it is given; it cannot be slapped on. If your paired receipts differ from the published benchmarks in direction, the first presumption is wiring: check the installation with section 42.5 of the manual (*Wired right or wired wrong*).

This is the test that answers "does Omni-Compass save real energy?" with the GPU's own power meter. There is no model in it. It has run on rented cards on Lambda, every receipt in `results/gpu/`: the A10 run of 2 October, on a card controller since replaced and so obsolete, and the runs from omni-v18 on (on one A10 on omni-v23 the energy for each request served fell 0.8% to 1.8%, GAIN in all three of our runs, `results/gpu/V23_A10_CAP_FULL_ABC.md`).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

63.1 What you need

- A Linux machine with one NVIDIA GPU (a rented cloud GPU works: A100, H100, L4, A10, RTX), the NVIDIA driver and `nvidia-smi`.
- Python 3 with PyTorch built for CUDA (`pip install torch numpy`).
- Root, because setting a GPU power limit (`nvidia-smi -pl`) needs it. Persistence mode on is recommended (`sudo nvidia-smi -pm 1`); the receipt records it either way.

63.2 Run it

```
git clone <this repository> && cd <it>
sudo bash scripts/gpu_paired.sh                       # 5 repetitions,
    ↪  10 minutes per arm: about 3 hours
sudo REPS=5 DURATION=300 bash scripts/gpu_paired.sh   # 5-minute arms:
    ↪  about 1.5 hours
```

Options (environment variables): `REPS`, `DURATION` (s per arm), `DRAIN` (s after arrivals stop), `COOLDOWN` (s idle before each arm), `GPU` (index), `SAMPLE_MS`, `INTERVAL` (s between Omni decisions), `SLO_MS` (response-time target; default ten bare service times), `WORKLOAD_ARGS` (e.g. `--n 8192 --target-ms 80`).

63.3 Two phases

- `PHASE=smoke` (the default): look for faults and for an effect worth a counted run. Any number of repetitions.
- `PHASE=confirm`: the preregistered test (`docs/GPU_PREREGISTRATION.md`), 10 repetitions. Omni's code must be committed; its files are hashed before the first arm and again after the last, and any change invalidates the run.

```
sudo PHASE=confirm bash scripts/gpu_paired.sh
```

The **primary outcome** is work per energy: requests served per kilojoule the GPU drew.

63.4 What it does

1. **Receipt.** GPU name, UUID, VBIOS, driver, kernel, host, persistence mode, power management, the enforced limit, default, minimum, maximum and current power limit, the workload's hash, the mechanism id, git commit (`receipt.json`). The current power limit is the **snapshot**; every arm must start and end at it. The bench refuses to start unless power management is Enabled (otherwise a written limit would not bind).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

2. **Calibrate once.** The workload times its request at the snapshot limit and picks the request size so one request takes about 50 ms (`calib.json`). Every arm uses the same calibration.
3. **Three arms per repetition, order rotated,** each after `COOLDOWN` s idle:
   - **native**: no Omni process.
   - **watch**: Omni runs, reads the GPU and decides, and is forbidden to write. This is the control: it shows what the machine does with Omni present and silent. If it writes even once, the run is invalid.
   - **omni**: Omni writes the GPU power limit.
4. **The same work in every arm.** `tools/gpu_workload.py` sends one seeded stream of requests (fp16 matrix products) at 30%, 60%, 80%, 30%, 60% and 30% of the GPU's full-power capacity. Every arm gets the same requests at the same moments.
5. **Measured by the device.** `nvidia-smi` samples power draw, temperature, utilisation, the power limit, the **enforced** power limit and the clock-limit reasons every 200 ms for the whole arm (the fields the driver reports, listed in `smi_fields.txt`); RAPL CPU package counters are read at both ends where the machine has them. This is receipt C, the outcome: Omni never supplies it.
6. **Reset.** After the omni arm Omni restores the snapshot limit and reads it back. The script checks the limit after every arm.
7. **The table** (`GPU_REPS.md`): each gauge for native, watch and omni, and three paired contrasts with 95% intervals — observation (watch − native), authority (omni − watch), total (omni − native). If an interval includes zero, it reads **STEADY, no difference beyond the noise**; wholly on one side, **GAIN** (or **LOSS**, or **power given**) **clear of the noise** (the words of amendment 14). The result label is chosen by rule (`docs/GPU_PREREGISTRATION.md`, amendment 1): SUPERIOR WITHIN GUARDRAILS, ENERGY IMPROVEMENT WITH SERVICE TRADEOFF, NONINFERIOR / INCONCLUSIVE, NOT ESTABLISHED, AWAY FROM ITS AIM, or INVALID. Also: actuator fidelity (receipt B), control effort and representation fidelity (receipt A). A meter that was not fitted prints UNAVAILABLE. The run folder holds every raw file and `SHA256SUMS.txt`.

63.5 What Omni does on the GPU (omni_controller/gpu_governor.py)

Every 2 s it reads the GPU and runs the Omni-Compass engine (the throughput law in `omnicompass/adapter.py`): load is GPU utilisation, power stress is draw over the snapshot limit, heat is temperature over 83 C, queue is response-time pressure. The engine's power cap becomes a power limit, inside hard rules:

- never below the GPU's current draw x 1.3, never below 0.70 of the snapshot (`--min-share`), never below the device minimum, never above the snapshot;
- a busy card (utilisation smoothed over decisions at or over 0.5, `--util-gate`) gets the snapshot limit back at once, and the cap returns only under 0.4;

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

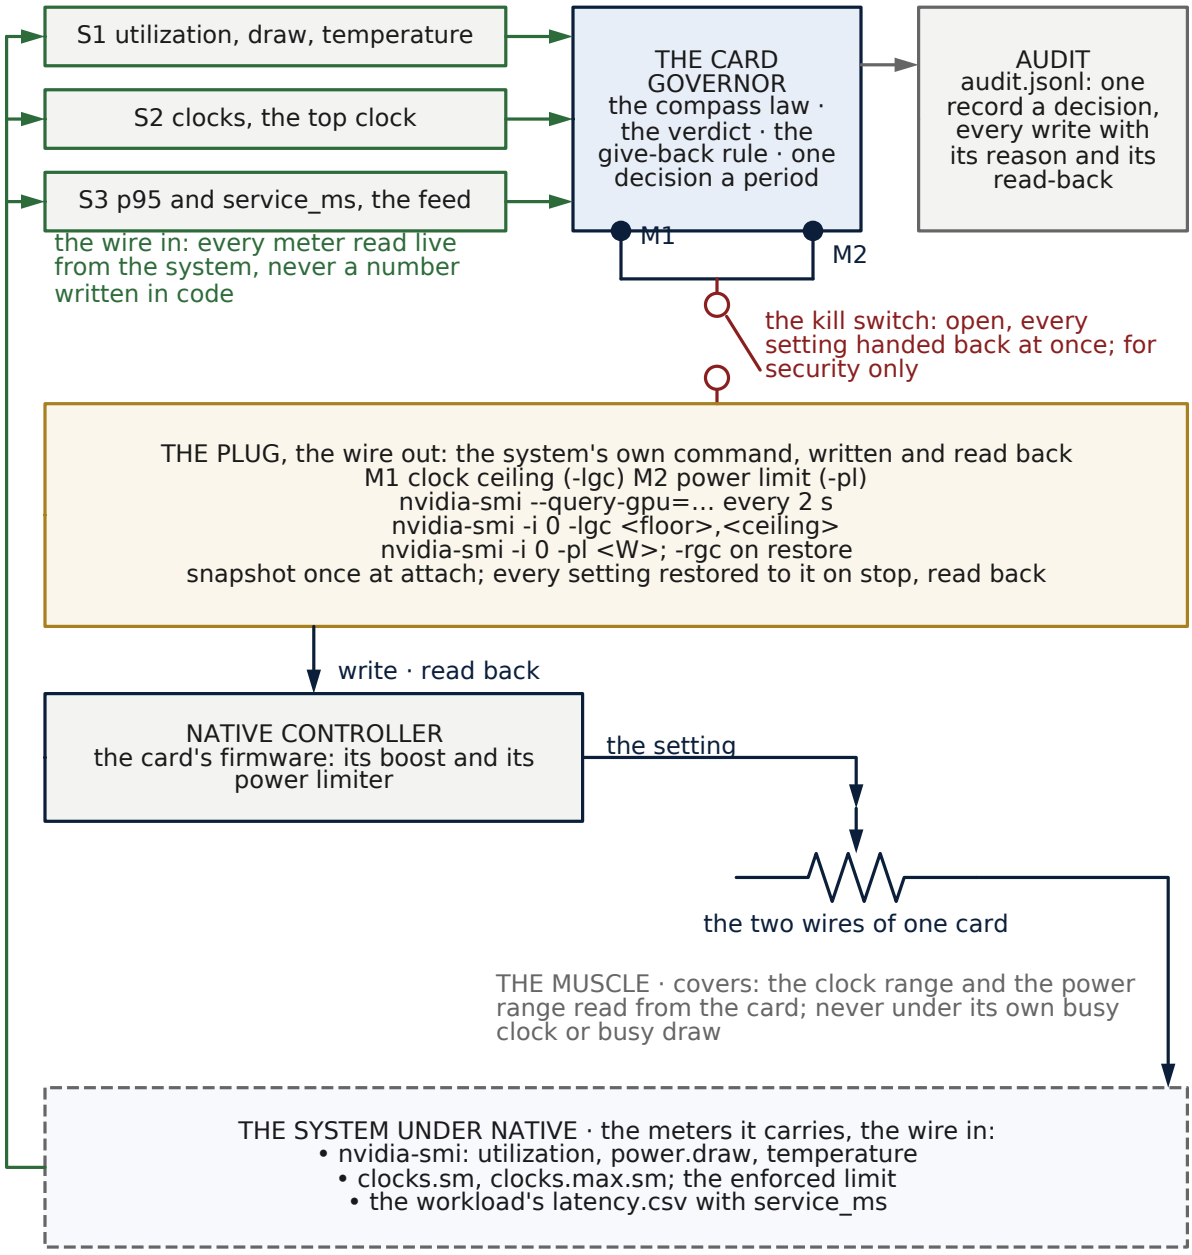

Figure 63. Wiring schematic: a graphics card, two wires. The schematic is read top to bottom as an electrical drawing: the governor (the control unit) with its sense terminals S1, S2, … on the left and its motor terminals M1, M2, … on its lower edge; the motor bus through the kill switch into the plug, the system's own command written and read back; the plug into the native controller; the native controller setting the muscle, drawn as a potentiometer with its cover; the system under native carrying the meters; and the meters back along one bus, the wire in, to the sense terminals.

The audit stands beside the governor. The senses are the card's utilization, draw and temperature, its clocks and top clock, and the workload's feed; the two motors are the clock ceiling (-lgc) and the power limit (-pl), both through nvidia-smi and both read back. Learns the card on its own first (15 busy readings); races while

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

work waits (≥ 95% utilization); at the max never below the top while the card serves; at the tune-down paces the slack in 15 MHz steps, each step through the paired trial.

- optional speed lock (`--baseline-file`, from `tools/gpu_baseline.py` on runs without Omni): the limit follows response time against that baseline, every gauge kept at least 1% faster (`docs/INTEGRATION_MANUAL.md`, level 5);
- no new write until the last one reads back from the device; every write is read back at once and recorded (requested, return code, read back, enforced limit, delay); the engine senses the enforced limit, the one the card obeys; a write the device refuses ends the arm (exit 4) and makes the run invalid; no clock locks are ever written;
- if it cannot read the GPU or the response times, the snapshot limit at once;
- if response time breaks its target, the snapshot limit at once, and for three decisions after;
- kill file or SIGTERM: the snapshot limit, read back.
- **one writer:** if the limit ever reads a value Omni did not write, Omni stops writing, leaves that limit alone, and exits 5 (the run is invalid);
- **heat fails up:** while the card reports a thermal or hardware slowdown, no lower limit is written;
- every decision names every rule that held the engine back (`blocked_by`) and the one that decided (`decided_by`).

Any workload plugs in through `WORKLOAD_CMD` (for example a vLLM or MLPerf inference harness), if it writes `latency.csv`, `requests.csv` and `summary.json` in `tools/gpu_workload.py`'s format and `SLO_MS` is given.

The table also credits each write: joules and requests against native at the same moments of the same stream, grouped by the rule that decided it. CPU energy comes from RAPL by domain: package and DRAM apart, psys never added, wrap undone. The card's own energy counter (NVML) and its ECC and retired-page counters are read at both ends of each arm.

63.6 Gauges

Gauge	From	Its aim
work per energy (served requests per kJ), primary	requests served / GPU energy	higher
energy, GPU (J)	power.draw integrated over the arm's window	lower
energy per served request (J)	the same, over requests served	lower
power, GPU mean (W)	energy / window	lower
requests served, not served	the workload's own record	more served, fewer not

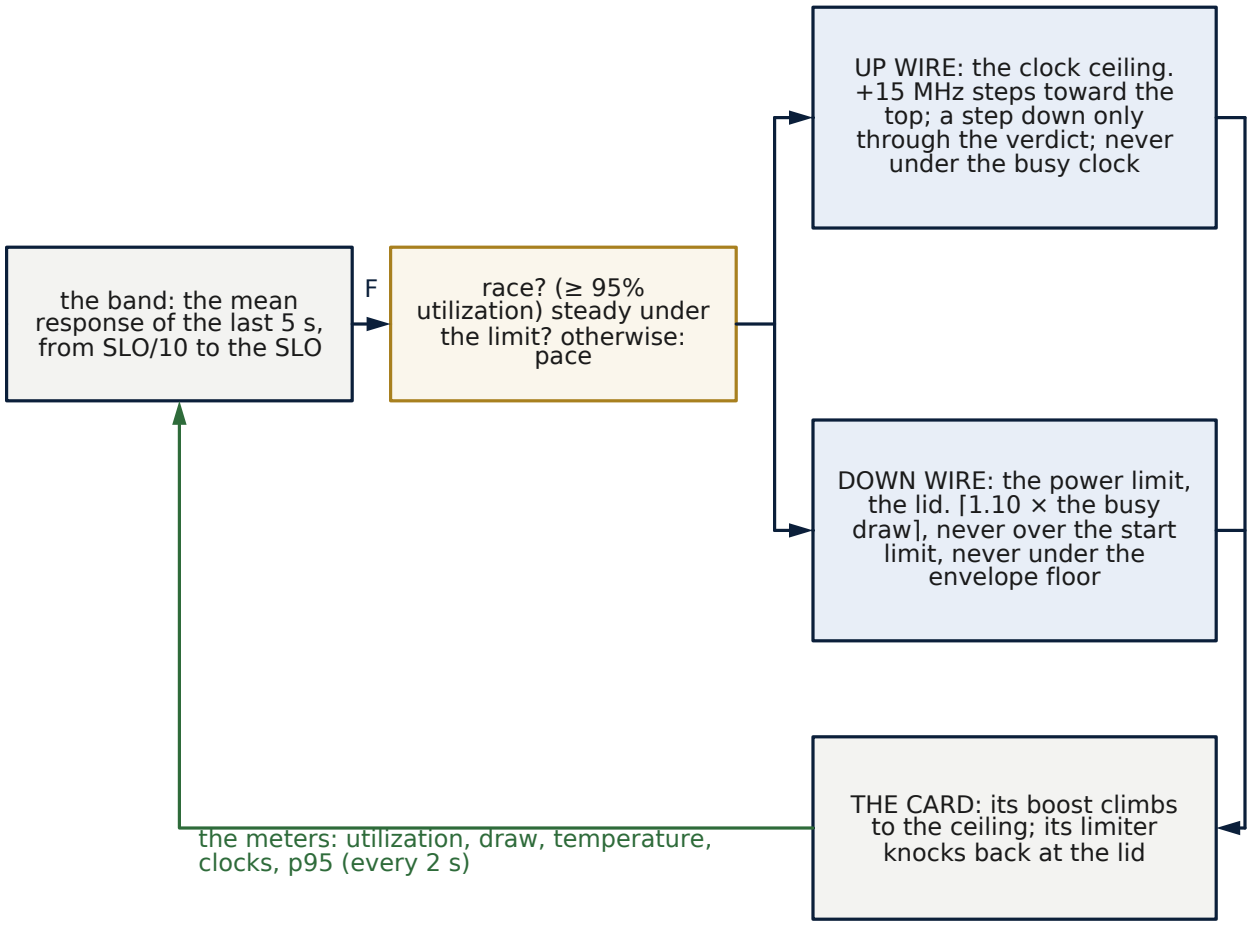
All patents, copyrights and trademarks filed in the USA.



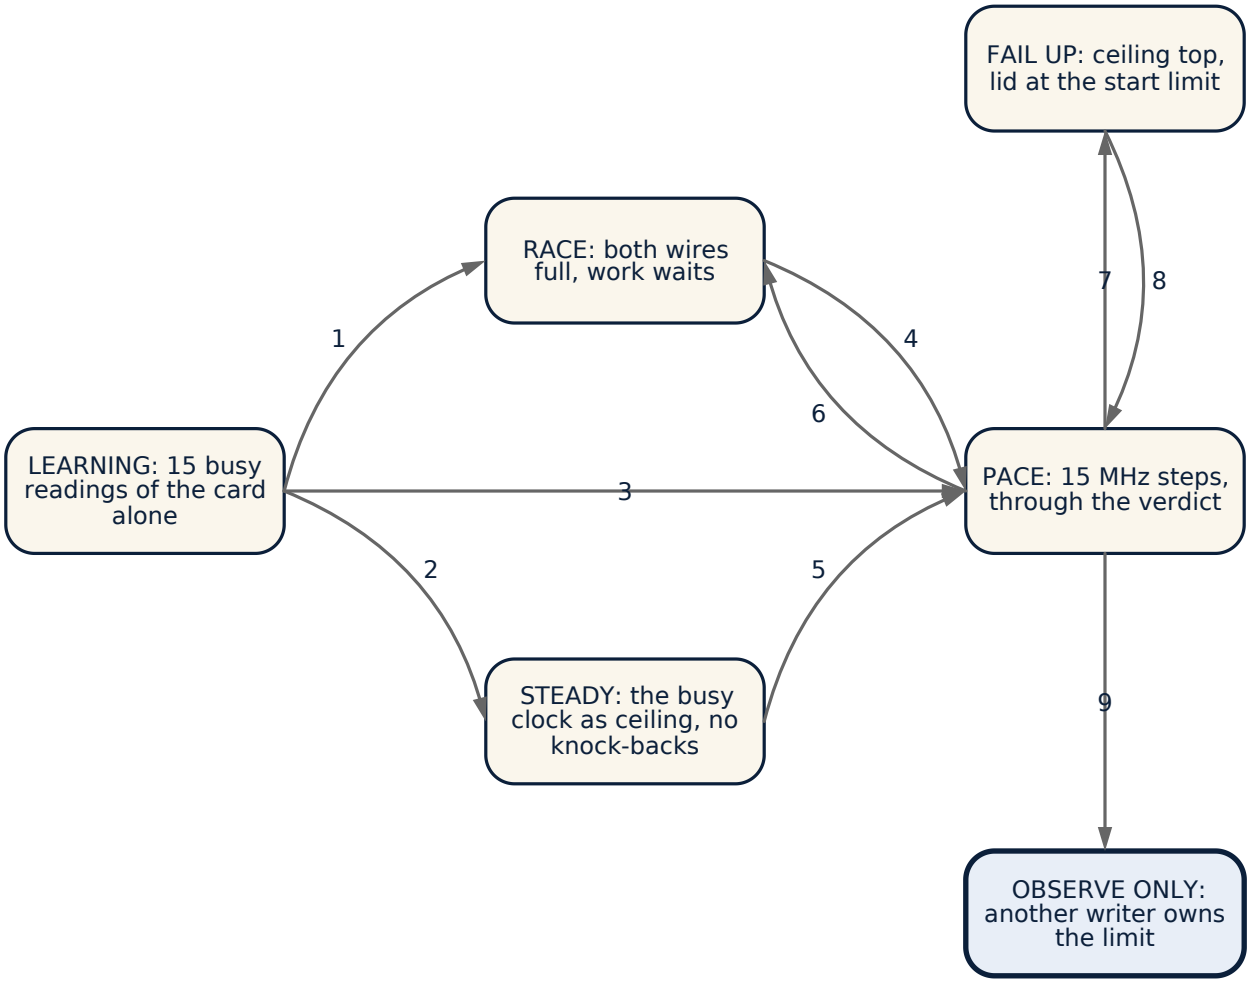


Figure 64. Block diagram: the two wires of a card as an antagonist pair. The band (the mean response of the last 5 s, from a tenth of the line to the line) yields the force F; the mode decides between racing (both wires to full while work waits, utilization ≥ 95%), steady under the limit (the card's own busy clock as the ceiling) and pacing.

The up wire is the clock ceiling, raised in 15 MHz steps toward the top and lowered only through the verdict; the down wire is the power limit, the lid at ⌈1.10 × the busy draw⌉, never over the start limit and never under the envelope floor. The card's own boost climbs to the ceiling and its own limiter knocks back at the lid; the meters close the loop every 2 s.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

1 learned; utilization ≥ 95% · 2 learned; saturated at an operator's cap (draw ≥ 97% of it) · 3 learned; slack · 4 slack (the tune-down) · 5 off the cap: slack · 6 work waits again · 7 from any state: p95 at the line, a failed request, a blind feed, a heat slowdown · 8 clear for --slo-clear · 9 from any state: a limit not written by the governor

Figure 65. State machine: the two-wire card governor. It learns the card on its own first (15 busy readings), then races while work waits (utilization at 95% or more), holds steady at the card's own busy clock while saturated under an operator's cap, or paces the slack in 15 MHz steps through the verdict; from any state it fails up on a breach, a failed request, a blind feed or a heat slowdown, and it observes only, for the rest of the run, once a limit is found that it did not write.

Gauge	From	Its aim
response time mean, 95th, 99th percentile (ms)	arrival to finish of each request	lower
temperature, peak and mean (C)	temperature.gpu	lower
energy, CPU package (J)	RAPL counters, when present	lower

63.7 Testing the bench without a GPU

`python tests/test_gpu_bench.py` runs the whole script against a stand-in `nvidia-smi` (`tests/standin_gpu/`), with the workload's `--sim` mode. The stand-in has no real power physics, so its numbers mean nothing; it proves the script, the controls and the validity checks work.

CHAPTER 64

The GPU Preregistration

Written before any hardware trial. The counted run (`PHASE=confirm`) hashes this file with the code in `FREEZE.json`; a change to either after the run starts invalidates it.

64.1 Question

On one NVIDIA GPU serving a fixed, seeded request stream, does Omni-Compass holding the GPU power limit change the successful work done per joule measured by the device, compared with the device left at its own limit?

Fixed here, before any smoke trial:

- the number of counted repetitions (10);
- the primary outcome;
- the guardrails;
- the analysis.

Nothing seen in smoke may change them.

64.2 Two phases

1. **Smoke** (`PHASE=smoke`, any number of repetitions). Its purpose is to find faults in the harness, and to see whether the effect is large enough to be worth a counted run. Smoke results are not published and are never reported as the result. After smoke, Omni's code may change.
2. **The counted run** (`PHASE=confirm`). Omni's code is committed and frozen before the first trial. The script refuses to run if any frozen file has uncommitted changes, and the table marks the run invalid if a frozen file changes during it. No inspection, tuning or rerun between counted trials. If the counted run fails, it is reported as failed; a new counted run needs a new commit and a new run, and both runs are reported.

64.3 Design

- **Arms:** native (no Omni), watch (Omni runs, may not write), omni (Omni writes the GPU power limit).
- **Repetitions:** 10 in the counted run, each with all three arms back to back, order rotated. Repetitions may run on separate machines of one GPU type (`REP_ONLY`, the GitHub workflow); the three arms of a repetition always share one machine, so every comparison is paired within a machine.
- **Per arm:** 60 s idle, then the pinned workload for 600 s plus 30 s drain.
- **Workload:** `tools/gpu_workload.py`, calibrated once at the start power limit before any arm. The seed is 20260928, and the load phases are 30, 60, 80, 30, 60 and 30% of full-power capacity.

64.4 Outcomes

- **Primary:** work per energy = requests served / GPU energy (kJ). GPU energy is `nvidia-smi` power.draw integrated over the arm's window.
- **Secondary:**
  - GPU energy;
  - energy per served request;
  - requests not served;
  - response time: mean, 95th and 99th percentile;
  - peak temperature;
  - CPU package energy (RAPL), where present;
  - where a smart plug is fitted (`WALL_METER`), whole-machine energy at the wall and work per wall kJ. The plug is read by the bench only, never by Omni. An arm whose plug readings have a gap over 5 s has no wall number.

64.5 Analysis

- **Primary comparison:** omni against native, paired by repetition. Report the mean difference with a two-sided t 95% interval.
- **Result:**
  - The result is *a proven GAIN* if the interval lies entirely above zero.
  - It is *a a proven LOSS* if the interval lies entirely below zero.
  - Otherwise it is *not proven*.
- **Guardrails, fixed now:** a primary GAIN counts only if Omni did not buy it with the work. Both guardrails must hold:
  - **Requests served:** the 95% interval of (omni − native) must not reach below −1% of native.
  - **95th-percentile response time:** the interval must not reach above +10% of native.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

If a guardrail fails, the verdict is *more requests per kJ, fails the service guardrail*. That is a different product and is reported as such.

- **Watch against native:** reported as the cost of Omni being present. If watch differs from native on the primary outcome as much as omni does, the effect is not attributed to Omni's authority.

64.6 Amendment 1 (2026-09-28, before any hardware trial; no smoke or counted data exist)

Added before any data, to make the chain from engine to plant identifiable. The question, the arms, the primary outcome, the repetitions, and the two guardrails above are unchanged.

- **Three contrasts, all reported, each paired by repetition:** observation = watch − native; authority = omni − watch; total = omni − native (the primary comparison). A total effect is not attributed to Omni's authority where the observation contrast differs materially from zero.
- **Third guardrail, errors:** the 95% interval of (omni − native) requests *not* served must not reach above +1% of native requests served.
- **Result label, by rule, never by hand** (`tools/gpu_reps.py`, `label()`):
  - primary a proven GAIN, all three guardrails held: **SUPERIOR WITHIN GUARDRAILS**;
  - primary a proven GAIN, a guardrail failed: **ENERGY IMPROVEMENT WITH SERVICE TRADEOFF**;
  - primary not proven, all guardrails held: **NONINFERIOR / INCONCLUSIVE**;
  - primary not proven, a guardrail failed: **NOT ESTABLISHED**;
  - primary a proven LOSS: **AWAY FROM ITS AIM**;
  - any invalidity below: **INVALID**.
- **The card obeys enforced.power.limit.** The snapshot records power.limit, enforced.power.limit, default, min and max limits, persistence mode and power management. The bench refuses to start unless power management is Enabled. The bench samples enforced.power.limit where the driver reports it. The governor senses the enforced limit and reads back every write at once; it never writes clock locks.
- **Also invalid:** a native or watch arm whose enforced limit differs from the snapshot; a governor that exits nonzero (a refused start, or a write the device refused — that write ends the arm); smoke and counted repetitions mixed in one table.
- **Three receipts, kept apart.** A (governor, `audit.jsonl` decisions): telemetry consumed; the six-state reading (history-dependent, `state_observed`); the memoryless state the telemetry alone points to (`state_measured`); the U-channel command u evaluated on the evolved state (`u_push`); admissibility; requested and granted authority; shield bound; holds. B (actuator, `actuator` records): requested limit, return code, power.limit read back, enforced limit, delay to realization, override (enforced under requested), restoration. C (outcome, the bench alone): nvidia-smi power, joules, temperature,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

utilization, clock-limit reasons; the workload's requests, latency and failures. Omni never supplies its own outcome.

- **Secondary, descriptive (no verdict):**
  - actuator fidelity: r[act] = read back − requested (mean and max absolute), delay (median, max), enforced-under-requested count, total variation of the realized limit, reversals, refused writes;
  - control effort: J_u = sum of abs(u[push]) × decision interval; mean and max abs(u[push]); saturations (abs(u[push]) = 25); shield interventions (a bound other than the engine decided); holds;
  - representation fidelity: R[int] = sqrt(mean over consecutive decision pairs of sum_k w_k (h(z_(k+1)) − F_h(h(z_k), u_k))_k^2) over E, U, I[U], S, B, weights 1, with h the memoryless map and F_h the engine's own projection (`state_projected_next`); directional accuracy = share of pairs where sign(projected − current reading) equals sign(next measured − current measured), both movements at least 0.01, per state and by predicted size (0.01–0.03, 0.03–0.1, ≥ 0.1);
  - energy of the rest of the machine = wall − GPU − CPU package, only when all three meters measured the arm. A missing meter prints UNAVAILABLE, never a modelled substitute.
- **Smoke never enters the counted run.** A smoke run that changes any code or parameter is followed by: repair, the tests, a new freeze, and a counted run collected from zero.

64.7 The run is invalid, and reported as invalid, if

- the watch arm executes any power-limit write;
- a native or watch arm sees a power limit other than the snapshot;
- any arm ends at a limit other than the snapshot (the reset failed);
- Omni's frozen files change during the run;
- the counted runs on uncommitted code.

64.8 Recorded for every Omni decision

Every decision is logged in `audit.jsonl`:

- the raw device telemetry: utilisation, draw, temperature, limit, SM clock, and clock-limit reasons where the driver reports them;
- the engine's six-state reading, the state it had projected for this moment, and the error against it;
- the projection for the next decision. This is the engine's own evolved state from the same step that sets the cap; no separate predictor was added for the experiment;
- whether change was admissible, the requested and granted authority, and which shield bound decided the limit;
- the limit written, and the requests served in the window.

All patents, copyrights and trademarks filed in the USA.

64.9 Amendment 2 (2026-09-28, before any hardware trial; no smoke or counted data exist)

Unchanged:

- the question;
- the arms;
- the primary outcome;
- the repetitions;
- the guardrails of amendment 1.
- **Watch must match native.** If the observation contrast (watch − native) on the primary outcome is proven in either direction, the label is **NOT ATTRIBUTABLE: WATCH DIFFERS FROM NATIVE** and no omni result is published.
- **One writer.** If the power limit ever reads a value that is neither Omni's last write nor the limit before it, another writer is present:
  - the governor stops writing for the rest of the run;
  - it leaves that writer's limit alone;
  - it exits 5;
  - the run is invalid.
- **Heat fails up.** While the device reports a thermal or hardware slowdown (clock-limit reason bits 0x8, 0x20, 0x40, 0x80), no lower limit is written.
- **Credit per write (descriptive).** Each write owns the interval to the next. For that interval, the table records GPU joules and requests finished, Omni minus native, at the same moments of the same seeded stream. It records who decided the write: the engine, a floor, the busy gate, a reflex, heat, or the speed lock. The table says which rule produced the joules; a speed-lock result is not credited to the engine.
- **CPU side (secondary, never on the control path).** RAPL counters are read by domain name at both ends of each arm:
  - `package-N` is summed as CPU package; `dram` is summed separately;
  - `psys` is recorded and never added to either;
  - wrapping is undone with `max_energy_range_uj`;
  - a counter that went backwards without a known range, or is missing, prints UNAVAILABLE.
  - The governor never reads these counters.
- **Device energy counter (cross-check, secondary).** Where NVML reports it (Volta and newer), the card's total-energy counter is read at both ends of each arm, beside the integrated power.draw.
- **Card health (descriptive).** Uncorrected and corrected ECC error counts, and pages pending retirement, are read at both ends of each arm.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Workload plug.** Any workload may be served through `WORKLOAD_CMD` if it writes the pinned workload's files. It needs its own response-time target (`SLO_MS`). The command is recorded in the receipt. A counted run names its workload before the first trial.

64.10 Amendment 3 (2026-10-01, before any hardware trial; no smoke or counted data exist)

No GPU job has ever been given a machine (every gpu-bench run so far waited in the queue and was cancelled), so no trial data exist. Unchanged:

- the question;
- the arms;
- the primary outcome;
- the repetitions;
- the guardrails, labels and invalidity rules of amendments 1 and 2.
- **Declared envelope, before any trial.** The buyer's service envelope is written to a file before the first trial and recorded with the run (`envelope.json` in the run folder and in every repetition):
  - `power_min_w`, the lowest watts Omni may set. Default (`tools/declare_envelope.py`): max(device minimum, 70% of the power limit read at declaration), rounded up to whole watts;
  - `power_max_w`, the power limit read at declaration;
  - optionally `slo_ms`, the response-time target; without it the target comes from calibration (10 bare service times), as before.
  - The bench refuses an envelope whose floor lies outside [device minimum, starting limit].
  - **The counted run refuses to start without a declared envelope** (`scripts/gpu_paired.sh`, `ENVELOPE`).
- **Envelope floor.** The governor never sets the limit under `power_min_w` (`--floor-w`). When the floor is what lifted a write, the decision record names it (`decided_by`: envelope_floor), so no saving below the floor can be credited to the engine.
- **Outer controller holds.** When the card's own controller (board, BMC or system policy) already holds enforced.power.limit under the current limit, a lower write that would still sit above that enforced limit changes nothing on the card. It is not written; the decision record marks it (`outer_controller_holds`). Only a write that would actually bind, or a return upward, goes out. This is not another writer (amendment 2): the set limit is unchanged and the governor keeps running.
- **Narrow cards are reported as they are.** The device's own limit range is in the snapshot. On a card whose range is narrow (for example a 70 W card that accepts 60–70 W), the envelope is that narrow range; the result is reported for that card and range and not extrapolated to wider cards.

All patents, copyrights and trademarks filed in the USA.

64.11 Amendment 4 (2026-10-02, after an invalid smoke; no counted data exist)

The first smoke on a rented A10 (results/gpu/smoke-20261002T032459Z, never counted) was invalid by rule: two copies of `scripts/gpu_rented_run.sh` had been started on the same machine, so both benches wrote the same card's power limit. The native and watch arms saw limits they never wrote (116, 137 and 150 W), each governor refused to start beside the other one (exit 5), and one reset restore was undone by the other copy. The card also began at 116 W, a limit an earlier start had left behind, not its 150 W default, so native itself ran capped (83% of samples). None of these numbers measures Omni. The engine, the governor, the outcomes and the analysis are unchanged. The run script now:

- **runs once per machine:** it takes a lock and refuses to start while another copy runs;
- **runs alone on the card:** it refuses to start while any other process is using the GPU;
- **starts from the card's default limit:** it sets power.default_limit before the envelope is declared, so the envelope, the snapshot and every arm start from the card's own default, not from a limit an earlier run left behind.

64.12 Amendment 5 (2026-10-02, before any valid hardware trial; the only smoke so far was invalid, amendment 4)

The Omni arm changes engine. The outcomes, the arms' order, the guardrails, the analysis and the validity rules are unchanged.

- **The Omni arm holds two wires** (`omni_controller/gpu_compass.py`, the compass law of `omnicompass/compass_law.py`): the clock ceiling (`nvidia-smi -lgc`, reset with `-rgc`; cover 35% of the top clock to the top), which sets how high the card's own boost may climb, and the power limit (`-pl`), the lid at what a fully busy card draws at that ceiling plus 10%, never under the declared envelope floor and never over the start limit. The service is read as one position between calm and the response-time line (the larger of p95 and utilization above half) and pulled to the middle; past 95% both wires go to full at once (fail up). The card's firmware keeps its own control; Omni sets only those two values. The earlier power-limit-only governor stays available (`OMNI_ENGINE=one_wire`) and is not the counted run's arm.
- **Why, before the run:** on a modelled card (`results/sim/gpu_two_wire/`, evidence class S, seeds never used while tuning) the one-wire governor gave +0.1% work per energy and the two-wire engine +9.0%. That is a model; this run is the card's own meter.
- **The watch arm** runs the same two-wire engine in watch mode: it computes and records both wires and writes neither.
- **The clock range is reset before and after every arm** (`-rgc`), as the power limit already was; the run script resets it once at the start.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **The wire check runs first** (`tools/gpu_wire_check.py`): the card's clock must follow a lowered ceiling down and come back up when reset, the power limit must read back what was set, the governor must hand both wires back when stopped and must leave a limit set by another writer alone (exit 5). If any step fails, nothing else runs and the check's report names the wire, the step and what the card said.
- **Wire check, corrected before any trial (2026-10-02):** on the A10 the first wire check failed at "3 up wire (follows up)" although the wire works: under the heavy check load the card's own 150 W limit already held it near 990 MHz, so a ceiling at 60% of the top clock (1017 MHz) left no room for the clock to come back up above it. The check now reads the card's busy clock on its own first and locks at 60% of that. The governor likewise starts its ceiling at the clock the busy card actually runs (a ceiling above it holds nothing), and its clock cover is 35% of the top clock to the top. No trial had run.

64.13 Amendment 6 (2026-10-02, after the first counted run and before any further trial)

What the first counted run showed (A10, commit `c908054`, `results/gpu/run-20261002T082232Z/`): work per energy +3.6% (+2.7% to +4.5%, proven), the same requests served, no request lost, but the 95th-percentile response time +58.5% (510 to 809 ms), so the response-time guardrail failed and the label by rule was ENERGY IMPROVEMENT WITH SERVICE TRADEOFF. It stands as the result of that run.

Why, from the card's own samples: while busy the card ran at 736 to 768 MHz under Omni against 861 to 889 MHz on its own, and spent about 30% more time busy for the same work; requests queued behind each slower one. Three faults in the governor, not in the engine: (1) the position counted utilization above half as service trouble, so every burst read as past the wall (fail up in 46% of decisions) and every quiet gap pulled the ceiling down, so each burst began on a lowered clock; (2) the lid followed a curve from the top clock and sat at the 105 W envelope floor in 49 of 165 compass decisions, under the 135 W the card itself draws while busy; (3) the ceiling's cover reached 35% of the top clock, far under the clock the card's own power limit holds it at while busy.

The Omni arm from now on (`omni_controller/gpu_compass.py`; the outcomes, arms, guardrails, analysis and validity rules are unchanged):

- the position is response time only (p95 over 5 s, not 30 s); being busy is not a breach;
- **race while work waits:** at 95% utilization or more the ceiling goes to the top and the lid to the start limit; the compass paces only the slack between bursts;
- **the card's own level, learned from its own meter** while the ceiling is at the top and the card is busy: its busy clock (median) and busy draw (90th percentile); until 15 such readings are in, neither wire moves;
- **speed floor:** the ceiling never goes under the card's own busy clock; **lid floor:** the lid never goes under the card's own busy draw plus 10%;
- fail up (past 95% of the line, or blind) is unchanged.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

On the modelled card, before any trial (`results/sim/gpu_two_wire/`, seeds 5000 to 5009): p95 122.1 ms native, 123.7 ms with the corrected compass; work per energy +8.2% (+6.3% to +10.1%); energy -7.5%; the median response 10.1 to 12.1 ms, slower in the quiet stretches the compass paces. That is a model; the next trial is the card's own meter.

64.14 Amendment 7 (2026-10-02, before any further trial)

The outcomes, arms, guardrails, analysis and validity rules are unchanged. The Omni arm of the counted runs the **service** profile.

- **Two profiles, one switch** (`--profile`, `omni_controller/gpu_compass.py`; the same in `realms/gpu_card.py`):
  - **service**, the default and the counted run's arm: down gain 0.0125, the compass's center at 0.4, the speed floor 3% above the card's own busy clock;
  - **batch**: down gain 0.015, center 0.5, the floor at the card's own busy clock, for work nobody waits on answer by answer. It may be run as a separate, declared counted run (`OMNI_ARGS="--profile batch"`) and is reported as its own result, never pooled with service.
- **How service was chosen, on the model, before the trial** (20 paired seeds, 5000-5009 and 5100-5109; ratios summarised as the geometric mean of the per-seed ratios): down gains 0.01, 0.0125, 0.015, 0.0175 and 0.02 alone, and 0.0125 to 0.0175 crossed with the compass's center (0.4, 0.5), the speed floor (1.00, 1.03 of the card's own busy clock) and the race threshold (0.90, 0.95). The rule: the most work per energy at which no seed's p95 is more than 10% slower than native. Service (0.0125, 0.4, 1.03) gave work per energy +5.3% (+4.2 to +6.5), energy -5.0%, p95 -4.1% (-9.7 to +1.7), worst seed +9%, 0 of 20 seeds more than 10% slower, p99 -1.8%; its neighbours gave the same within a point. 0.015 alone gave +6.2% but 3 of 20 seeds 10% to 48% slower at p95; 0.01 alone gave +3.8% with p95 -1.9%.
- **The ceiling moves in whole clock steps** (--min-change-mhz, 15 MHz), as the card's own clock does and as the model moves it: the force times the gain, as a share of the top clock, is rounded to whole steps, and a pull under half a step moves nothing and is not stored up.
- **The position reads the mean response time of the window** (as the model does), between the bare service time and the line; the 95th percentile at or past the line, or any failed request, is past the wall (fail up).
- **The model's report summarises ratios on the log scale** (`tools/run_gpu_card.py`): the arithmetic mean of per-seed percentages let one seed (+240%) stand for twenty.

64.15 Amendment 8 (2026-10-03, before any further trial)

The outcomes, arms, guardrails, analysis and validity rules are unchanged, except as stated here.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Omni-Compass moves the card only where it measures that the card is never behind for it** (`omnicompass/verdict.py`, in `omni_controller/gpu_compass.py` and `realms/gpu_card.py`). While the service is calm, the governor runs a paired trial:
  - first the ceiling at the top until 30 requests are measured;
  - then one 15 MHz step past the deepest step already allowed, until 30 more are measured.

Each request's cost is the card's own time on it: the workload's new `service_ms` column, start to done, with the wait in the queue left out. The step is allowed if its median cost is at most **2%** above the median at the top. Otherwise it is refused and not tried again for 900 decisions. The compass may move the ceiling only between the top and the deepest allowed step. Where no step passes, the ceiling stays at the top and the card runs as it does alone. Every trial and every judgement is in the audit (`verdict`, `verdict_state`, `verdict_deepest_step`).

- **One law, no profiles.** The service and batch profiles are removed. The law is: down gain 0.0125, the compass's center 0.4, the speed floor at the card's own busy clock, and the verdict's allowance of 2%. The batch profile paced past the 2% allowance, so it is gone.
- **Why 2%** (the card model, 20 paired seeds):
  - an allowance of 0 leaves the card native on every workload, because every clock step down adds some time to a request, and saves nothing;
  - 2% is the smallest allowance that saves energy, and it is below what a person or a service contract can notice.
- **A second workload, AI token generation** (`tools/gpu_workload.py --kind decode`): fp16 matrix-times-vector over 1 GiB of weights per pass, batch one, so each pass streams every weight from memory, as token generation does. It runs as a second counted run of the same design (10 repetitions × 3 arms × 600 s) after the compute-bound one (`scripts/gpu_rented_run.sh`; `SKIP_DECODE=1` skips it). It is labelled by the same rule and reported as its own result, never pooled.
- **Every comparison is a base alone against the same base with Omni on top.** The model's report (`tools/run_gpu_card.py`) runs two bases:
  - the card's own firmware, alone and with Omni on top;
  - an operator's fixed 105 W power cap, alone and with Omni on top.

The old one-wire governor is removed as an arm (it was Omni's own earlier version).

- **On the modelled card, before any trial** (`results/sim/gpu_two_wire/`, firmware alone against firmware with Omni on top; tuning seeds 5000-5009, fresh seeds 5100-5109):
  - compute-bound work: work per energy +0.70% (tuning) and +0.48% (fresh); median +1.56% and +1.47%; p95, p99 and time over the line unchanged within their intervals;
  - AI token generation: work per energy +3.36% and +3.86%; median +0.55% and +0.70%; p95 +0.29% and +0.26%; time over the line 0.

That is a model; the next trial is the card's own meter.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

64.16 Amendment 9 (2026-10-03, before any trial on this code)

Everything in amendment 8 stands. Four additions, each run by `scripts/gpu_rented_run.sh` after the two counted runs and each reported as its own result:

1. **Steady under the limit** (`omni_controller/gpu_compass.py`, the same in `realms/gpu_card.py`). While the card is saturated against its own power limit (work waiting, the draw at 97% of the limit or more), the firmware boosts a step, hits the limit and is knocked back. The ceiling is then held at the card's own busy clock under that limit, so the same watts serve the work without the knock-backs. It is never held under that clock, the lid stays at the start limit, and a blind feed still fails up. In the card model, fully loaded under a fixed cap, this gives about +0.6% requests served from the same watts, with p95 about 2% faster.
2. **An operator's power cap underneath.** The card's limit is set to the envelope's lowest watts (70% of its default) before the run, and the paired bench runs native (the cap alone), watch and Omni-Compass on top of the cap (the lid never above the cap). It runs twice, 5 repetitions × 3 arms × 300 s each time:
   - at the usual load;
   - fully loaded (arrivals at 130% of the card's capacity under the cap), so the result is requests served from the same watts.

The card is returned to its default limit afterwards.

3. **The GPU fault drill** (`scripts/gpu_fault_drill.sh`). With the request stream running:
   - the governor is killed outright, and the watchdog must hand the card back;
   - the master switch is pulled, and the governor must hand back, exit and refuse to restart while OFF;
   - the response feed is paused, and the governor must fail up.

Every check must pass, and the card must end at its start limit.

4. **Real AI serving** (`scripts/gpu_vllm.sh`, `tools/llm_workload.py`). An open language model (Qwen/Qwen2.5-0.5B-Instruct) is served by vLLM, installed in its own environment. It is asked the same seeded stream of prompts in every arm, each for exactly 128 new tokens; 5 repetitions × 3 arms × 300 s. Tokens per second and tokens per kilojoule follow from requests served. If vLLM cannot be installed or started on the machine, the stage says so and nothing measured before it changes.

64.17 Amendment 10 (2026-10-03, before any trial on several cards)

Everything in amendments 8 and 9 stands. **Several cards in one server** (`scripts/gpu_8card.sh`): every card runs `scripts/gpu_rented_run.sh` at the same time, each on its own card with its own wire check, envelope, smoke, the two counted runs and the power cap underneath, on the same committed code. Card i starts its arm rotation i steps later (`ROT_OFFSET`), so no arm always meets the same neighbours. Each repetition stays paired within its own card (its three arms on one card); the pooled table per workload holds every card's repetitions (card c, repetition r is pooled as repetition 100(c+1)+r) and is labelled by the same

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

rule. Each card's own table is reported beside it; a card whose table is invalid is reported, never dropped. The fault drill runs once, on the first card, after every card has finished. Last, **one model across every card** (`scripts/gpu_vllm.sh` with GPU = every card): vLLM tensor parallel, Qwen/Qwen2.5-7B-Instruct, one governor per card on its own card's two wires, all reading the same response times; the energy is every card's summed; 5 repetitions × 3 arms × 300 s, labelled by the same rule. Each card's energy is read from that card alone (the bench's sampling filtered to the card in each repetition's own receipt).

The short design (`FAST=1`, written before any trial on several cards): each card runs one smoke round and 3 repetitions of the compute counted run (24 paired repetitions on 8 cards, pooled and labelled by the same rule, each card's own table reported beside it), then one model across every card with 3 repetitions. AI token generation and the power cap underneath are measured on the one-card machine (amendment 9) and are not repeated here.

The whole stacks with a real card inside, on several cards (written before any trial): `tools/run_hil.py` as on the one-card machine (amendment 9, the six organisms at 1x, 10x, 100x and 1,000x, repetitions 3, 3, 2, 1 by size, the adaptive step), each organism on its own card at the same time (organism i on card i; with fewer cards than organisms, the next organism waits for a card). Each organism's receipt is its own; nothing is pooled across organisms.

The pooled design (`POOLED=1`, written before any trial on several cards): every stage of the whole design, with the repetitions pooled across the cards. Each card runs one smoke round; 3 repetitions of the compute counted run and 3 of the AI token generation counted run (24 paired repetitions per test on 8 cards, pooled and labelled by the same rule, each card's own table beside it); 2 repetitions of each power cap load (16 per load); the six organisms with the card inside, one repetition per size, each organism on its own card; then one model across every card, 3 repetitions; the fault drill once. Arm durations are those of the whole design.

The time budget (`MAX_HOURS`, written before any trial on several cards): a run on several cards ends by its budget whatever happens. At the budget the master switch is pulled (every governor hands its card back), every stage still measuring stops and is reported as incomplete (an arm cut short is never counted: its repetition has no complete pair), the stages not started are skipped and named, and the finished ones are packed.

64.18 Amendment 11 (2026-10-04, before any trial on this code)

The six organisms with the card inside (`tools/run_hil.py`), first run 2026-10-02 at commit `c908054`, labelled the card's part SUPERIOR in five organisms while its 95th percentile rose from about 500 ms to 600-935 ms in every organism. The harness counted the card's work and energy and never its response time (its time over the line was fixed at zero). That run is history: its governor was replaced in amendments 6 and 7, and its labels do not meet the founder's rule.

From this amendment the card harness measures what it never counted:

- the card's time over the line (requests slower than the line, ten bare service times, percent of requests) and its 95th percentile, each paired against native;

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- each row keeps its preregistered label and names, beside it, every measure that came out behind native by any amount, so what Omni costs is read beside what it gains; every change is read in words (GAIN, EVEN or LOSS, and what it means); no new line is drawn. The 2% bound stays where the founder set it: inside the engine, as the trigger of the verdict (`omnicompass/verdict.py`: a knob moves only where a paired trial shows the muscle at most a 2% LOSS);
- the stacks' own label (`realms/harness.py label`) puts the band first: its guardrail is the mean time over the line at or under native's, where it was the upper end of the interval under +1 point;
- at one copy, each organism runs 5 paired repetitions (was 3), so an energy change of 1-3% on the card's own meter can be told from noise; 3, 2 and 1 at 10, 100 and 1,000 copies as before.

The single card and the eight cards run this code. A card run started before this amendment is reported in full from its own raw files (its response times included) before any figure is quoted.

Why the stacks were late more often in the first run (+0.25 points) and are not now (-0.03): two knobs moved in commit `2a9285d`. Omni could loosen the operator's HPA target to 0.95 (fewer pods, bursts wait); it is now held at the operator's. A machine went back with no headroom (the next burst waits for a boot); it now goes back only when the rest covers the recent peak at 0.6 of the release level. Each alone leaves the stacks late more often; together they are late less often. The headroom is the least that keeps every seed un-late (`results/realms/RELEASE_MARGIN_SWEEP.md`).

Every report reads each change in words (GAIN, EVEN or LOSS, and what it means), so a sign is never read alone.

64.19 Amendment 12 (2026-10-05, before any trial on this code)

The card model rerun on the current code (`tools/run_gpu_card.py`, 2026-10-05) showed amendment 9's steady hold making the card slower on its own firmware: compute work, p95 122 ms native against 149 ms with Omni on top, time over the line +0.39 points. A bisection over every commit since the last clean model run puts the change in commit `bd455f9` (amendment 9, item 1). Holding the ceiling at the card's median busy clock takes away the boost the firmware uses to serve a burst at its own factory limit. Under an operator's cap the same hold is what helps: the firmware sawtooths against the low cap, and the hold smooths it.

From this amendment the hold applies only under an operator's cap: the start limit under the card's factory limit, read from the card (`power.default_limit`). If the card will not say, it is treated as no cap, so no hold, and the firmware is left to serve the burst. On the card's own limit, saturated, Omni races, as it did before amendment 9. Test: `tests/test_gpu_compass.py` (no hold at the factory limit; the hold under a 150 W cap on a 214 W card).

The card model with this amendment, 20 seeds (tuning and fresh). Under the cap: p95 6.4% and 7.1% faster, p99 3.2% and 5.8% faster, time over the line 1.3 and 1.0 points lower. On the firmware: energy 0.5-3.7% lower, p95 even. The median is 0.6-1.5% slower, inside the verdict's allowance (`results/sim/gpu_two_wire/`). The real card is the test.

All patents, copyrights and trademarks filed in the USA.

64.20 Amendment 13 (2026-10-13, before any trial on this code)

The founder's order of 12 October: 1, 10 and 100 only, to cut the time and the bill; no 1,000 copies and no 1,000 runs anywhere. The whole stacks with the card inside (`tools/run_hil.py`, step 8 of the one-card and eight-card runs) now run each organism at 1, 10 and 100 copies on one clock, with 5, 3 and 2 paired repetitions by size (amendment 11's numbers for those sizes); the 1,000-copy size is gone. On eight cards with the repetitions pooled (amendment 10), each card's organism runs once per size. Nothing else changes: the arms, the measures, the labels and the hand-back are as before. On one card the stage takes at least 16 hours (60 paired repetitions, each arm 240 steps of 2 s; a size whose step must be longer is measured on the machine and stated in the receipt), where it took about 25 with the 1,000 copies.

64.21 Amendment 14 (2026-10-17, wording only, before any trial on this code)

The rule of the analysis and of amendment 1 is unchanged; only its words change, so a reading never claims more than a 95% interval can carry and every word matches the house key (GAIN, EVEN, LOSS; `docs/HOW_TO_READ_THE_RESULTS.md`):

- "a proven GAIN" and "a proven LOSS" (the interval wholly on one side of zero) are written **GAIN, clear of the noise** and **LOSS, clear of the noise** (a card's energy that rose: **power given, clear of the noise**);
- "not proven" (the interval includes zero) is written **EVEN, no difference beyond the noise**;
- a contrast with fewer than two repetitions has no interval and says so.

The labels of amendment 1 read the same way: primary GAIN clear of the noise, all three guardrails held: SUPERIOR WITHIN GUARDRAILS; a guardrail failed: ENERGY IMPROVEMENT WITH SERVICE TRADEOFF; primary EVEN, guardrails held: NONINFERIOR / INCONCLUSIVE; a guardrail failed: NOT ESTABLISHED; primary LOSS or power given clear of the noise: AWAY FROM ITS AIM; the observation contrast clear of the noise: NOT ATTRIBUTABLE. The intervals use the two-sided 95% point of Student's t computed for the run's own degrees of freedom (`omnicompass/student_t.py`); the table it replaces held the same values to the last digit up to 20 degrees of freedom and fell to 1.96 beyond them. The first counted run's table (2 October) keeps the words it was printed with.

64.22 Amendment 15 (2026-10-30, the rig, declared before any counted run on it): the window opens once the governor stands

Until this amendment `scripts/gpu_paired.sh` wrote `window_start.txt`, read the energy meters and started the workload the instant the governor process was launched, so the governor's own start-up (the interpreter, the first query of the card, the snapshot of its limits) was inside the omni and watch arms' windows and outside native's. On a rented card it is a second or two of a 600 s arm; on a loaded machine running the harness's own 5 s test arm it was most of the arm, and the governor had written nothing by the window's end (found 30 October 2026, `tests/test_gpu_bench.py` on a loaded runner). From this amendment every

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

governed arm waits for each governor's first audit record (its snapshot, written before its first decision), records that moment in `governor_ready.txt`, and only then reads the meters and opens the window; a governor not standing within `GOV_READY_S` (60 s) refuses the arm. Native's window is unchanged. No gauge, rule, gain or guard of the governor changes, and `tools/gpu_reps.py` reads the window as before. The card tables already run (omni-v18's A100 run of 24 October; omni-v21's A100 tables of 27 October) stand as their own rig's; the next counted runs carry this rig.

64.23 Amendment 16 (2026-11-01, declared before any run of it): the stacks with the card fully loaded

The founder's design of 1 November reads every place by its bill and the work done inside it (`results/TWO_BILLS.md`): the chip native (A) and the chip with Omni-Compass on native (B), the cloud native (C) and the cloud with Omni-Compass on native (D). The whole stacks with the card inside (amendment 9; omni-v21's three runs, `results/gpu/V21_STACKS_A10_ABC.md`) offer the card the usual load (shares 0.3 to 0.8 of its full-power capacity), so the card serves every request in both arms and its work cannot differ: there the work is the same by construction and only the energy can move. This amendment adds a second form, `lambda-gpu.yml` mode `stacks-full`, and changes nothing in the first:

- the card's workload inside the stacks offers 1.3 times its full-power capacity in every phase (`--phases=1.3,1.3,1.3`, the same full load as the power cap's `cap-full` form), through `HIL_WORKLOAD_ARGS`, which reaches the stacks alone: the wire check and the smoke keep their own load;
- everything else is the stacks' as declared: the seven organisms (the spine, the four realms, the four stacked, the whole tower) at 1, 10 and 100 copies with the card inside, repetitions 5, 3 and 2 by size (`hil_profile standard`), native against Omni-Compass on native at the factory tune (the dial at the max), paired within each repetition, the card's firmware limit as it ships in both arms and no operator's cap;
- three runs, A, B and C, each on its own rented A10, on one commit that carries the engine that stood when it was declared (omni-v23);
- the reading: per organism and size, the card's requests served (work), its energy, its energy per request served, its 95th percentile and its time over the line, and the stacks' own gauges, each by the one key (`tools/readings.py`); the bill of each arm is the rental of its own window at the price the launch printed, so the bill reads the same in both arms unless a window differs, and the work per dollar moves with the work;
- said before the run: the A10 ships with its power limit at the top of its range, so on native the card already runs at its limit and the factory tune, never below native, may have nothing to raise (omni-v18's A100 run of 24 October wrote nothing for that reason). A STEADY row where the governor wrote nothing is that, said so: not a benefit and not a fault.

CHAPTER 65

The Realms Preregistration

Round 3 is the current one: its section at the end changes only how the realms are made up. Round 2's section replaced round 1's Omni layer. Round 1 below is kept as it was frozen. Each round was written and committed before its counted seeds were run. Evidence class **S**: every number the run produces comes from a declared model. Nothing here is a meter, and nothing here is evidence about a real machine.

65.1 Question

For each of the 656 muscles of the canonical tower, and for each realm and the whole tower run as one organism: does the frozen governor (`omnicompass.adapter.Governor`, the engine with u = 0, the stack law, the reset), holding that muscle's one knob on top of the plant's native controller, change work per energy against the native controller alone, without buying it with service?

65.2 What runs

- **The catalog** (`realms/catalog.csv`, built by `tools/realms_catalog.py`): the 656 rows of the XPASS package's canonical tower, unchanged, plus four columns given by fixed rules: realm, plant, parameter set, knob.
  - Compute / AI / Cloud: 250 muscles. Physics / Robotics / Autonomous: 88. Energy / Facility / Industrial: 121. Distribution / Specialized: 197.
- **Five plants** (`realms/plants.py`), each with its own native controller, all parameters in `realms/presets.py`:
  - compute_pool: request stream, servers with start-up delay, idle and dynamic power; native: the HPA rule (10% tolerance, scale-down stabilisation window), fixed admission limit, full clock;
  - thermal_zone: zone heat balance, staged cooling units, COP from supply and outdoor temperature; native: PI on a fixed setpoint, units staged to the load;
  - energy_storage: site load, solar, battery, grid connection with a contract limit; native: self-consumption above a fixed reserve;
  - motion_axis: point-to-point moves from a task queue, motor copper losses and heating, derating; native: PID with feedforward at full speed;
  - process_loop: first-order process with dead time, pump or heater power; native: PI on a fixed setpoint.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **A muscle is one knob of one plant.** Omni holds only that knob: capacity (the adapter's capacity law for one plant), setpoint (inside a declared band: calm end at rho0, stress end at rho_min), power (the directive's power cap), or admission (native while change is permitted; while not, only what clears inside the service target, or the flexible share deferred or shed).
- **Each muscle's plant is sized** by a factor 0.6 to 1.4 drawn from its muscle id.

65.3 Arms

On the same seed, so with the same demand, weather and disturbances:

- **native**: the plant and its native controller;
- **watch**: the governor reads every period and writes nothing;
- **omni**: the governor holds the knob; at 90% of the run it is killed and the knob returns to the native controller;
- **fixed_calm** (setpoint muscles only, descriptive): the native controller with the setpoint fixed at the band's calm end. It shows how much of a setpoint result the band alone gives.

Organisms: every plant of a realm (or all 656) on one 15 s clock for one hour. Plants are coupled:

- the electrical power of compute, motion and process plants is heat in the realm's thermal zones;
- the organism's load swing is load on its storage sites;
- the zones' temperature is the ambient every other plant reports.

One governor reads the organism's aggregate, and its one directive sets every muscle's knob.

65.4 Seeds and repetitions

Counted seeds 1000 to 1009: ten paired seeds per muscle and per organism. Development used seeds 0 and 1 only. Nothing from development seeds is reported.

65.5 Outcomes

- **Primary**, per seed: (work_omni / work_native) / (energy_omni / energy_native) − 1. Work is in the plant's own units: requests, IT heat held in specification, site load served, moves completed, or product delivered in specification. For an organism, work is the mean over its plants of work_omni / work_native, and energy is total joules.
- **Guardrails**, both must hold:
  - work: the 95% interval of work_omni / work_native − 1 must not reach below −1%;
  - violations: the 95% interval of the change in the share of periods in violation must not reach above +1 percentage point.

Violation, per plant:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

  - compute: response time over the service target, or a dropped request;
  - thermal: zone over its limit;
  - storage: grid import over the contract limit;
  - motion: tracking error over its bound, winding over temperature, or the oldest task waiting past its deadline;
  - process: the process variable outside its specification.
- **Label, by rule** (`realms/harness.py`, `label()`, the GPU bench's rule):
  - SUPERIOR WITHIN GUARDRAILS;
  - ENERGY IMPROVEMENT WITH SERVICE TRADEOFF;
  - NONINFERIOR / INCONCLUSIVE;
  - NOT ESTABLISHED;
  - LESS WORK PER ENERGY;
  - INVALID.

65.6 Invalid

A muscle or organism is labelled INVALID if, on any seed:

- the watch arm differs from native in any meter or writes anything;
- the omni arm writes after the kill;
- a knob is not back at its native value after the kill;
- any contrast is not finite.

65.7 Recorded

Per muscle and organism:

- every per-seed contrast;
- writes per run;
- the native violation share;
- the fixed-setpoint comparison where it applies.

Per run: the commit, the seeds, and the fingerprints of the catalog, the engine, the governor and the whole frozen tree (`RUN.json`, `SHA256SUMS.txt`). The counted run refuses to run on uncommitted code.

65.8 Changes made on the development seeds, before this freeze

The development runs found bugs and sizing faults. Each was fixed before the counted seeds were run:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **The admission knob was inverted**: it admitted only what cleared the service target while change was permitted. Fixed to the declared rule.
- **The compute admission limit compared the queue limit with the period's arrivals** instead of the backlog left after the period's service. Fixed for native and Omni alike.
- **The capacity law did not clip the queue and load readings to [0, 2]**, as the adapter's `observe_vector` does. Fixed.
- **Thermal and process utilisation was measured against the uncapped capacity** while the power cap was held, so the power law's trim ratcheted to its floor. Fixed: utilisation of the capacity actually available.
- **Compute plants reported a heat proxy of my own.** Replaced by the live controller's own thermal model (`omni_controller/muscles.py`).
- **Thermal zones kept fixed cooling units while their IT load was scaled.** The large halls were under-provisioned, so the native controller overheated. Cooling now scales with the hall.
- **The flight axis's motor thermal resistance was ten times too high**, so the native controller was always derated. Corrected. The UPS feed was sized under its own load; sized at 1.2 times.
- **The slow plants** (vehicle, spacecraft, flight) completed too few tasks in six minutes to measure. They now decide every 5, 10 and 2 seconds over the same 360 decisions.
- **Added the fixed_calm arm** for setpoint muscles, after development showed that the band's calm end alone accounts for much of the setpoint results.

None of these changes was chosen by its effect on Omni's result. The development runs showed losses as well as gains for Omni before and after them.

65.9 Not claimed

- **No row is evidence about a real machine.** A row says what the governor's law does to that model through that knob.
- **The plants, native controllers and bands were written by the same project as the governor.** That is a real conflict, so every one of them is in two files, to be read and contested.
- **A muscle's name chooses its knob and its plant's size; it does not get its own physics.** The 16 muscles of a family share the family's plant model at different sizes, through different knobs.
- **The plant code is Python only.** The governor's C++ twin is unchanged; a C++ twin of the plants is open.

65.10 Round 2 (2026-10-01, after round 1's results; before any round-2 counted seed)

Round 1 (seeds 1000-1009) labelled all five organisms LESS WORK PER ENERGY. Reading the result against the shipped controller (`omni_controller/controller.py`, `omni_controller/muscles.py`, `omnicompass/nervous_system.py`) showed that round 1's

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Omni layer was not the Omni that runs on Kubernetes. Round 1 is kept unchanged in `results/realms/round1/`, with a note saying why it is superseded. Round 2 changes only how Omni commands a knob, the native machine-pool scaler and the declared budgets. These changes were made after seeing round 1, so they are listed with the source line each one follows:

Round 1	Round 2, as the shipped controller does it
Capacity muscles replaced the HPA with the stack simulator's capacity law (release one unit after convergence, dwell and a 20% band)	Pods: the HPA target written as min(rho*, the operator's target), never tighter, held one autoscaler window; the HPA scales (`controller.py`, HPA target patch). Machine pools: the node release gate, one machine per decision (`nervous_system.node_release_gate`)
HPA-type setpoints moved inside a band whose calm end was tighter than the operator's target	The same min(rho*, operator) rule: more headroom is always allowed, less never (`controller.py`)
No contraction authority and no SLO reflex	Every contraction needs the organ's authority (calm >= threshold, senses live) and three clean decisions; while service is breached the knob returns to native (`nervous_system.authority`, `muscles.py` SLO reflex)
Continuous knobs jumped to the governed value	Down by at most the calm share of the surplus per decision (`nervous_system`: step = calm)
Request-served pools had their power capped	Never: throttling request work saves no energy and adds wait (`muscles.py`, `_power_cap`); GPU and CPU-frequency pools use their envelope, never under draw x 1.3
Thermal setpoint by headroom	The live cooling law: warm while cool, cold as heat rises, under the envelope 18 + 9 x calm mapped onto the band (`muscles.py`, `_cooling`)
Admission paused every admission muscle, request traffic included, and resumed only when fully calm	Batch pacing of pausable work only: one muscle suspended per decision at power stress >= 0.95 or heat >= 0.96 (or a nervous pause), one resumed per decision at power stress <= 0.8 and heat < 0.90 (`muscles.py`, `_batch_pace` defaults); request traffic never paused
queue_ratio was the backlog in service-target units	pending starts per serving unit, or latency pressure (p95 / target − 1, or the failed share), capped at 2 (`controller.py`)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Round 1	Round 2, as the shipped controller does it
The governor's current cap followed the applied cap	1.0, as the live controller sets it
Site power budget 1.25 x a formula nominal that sat under the organism's real native draw (compute ran at 1.2 x it), so the governor read the site as always at its limit	1.25 x each plant's mean native draw on the calibration seed 999 (never a result seed); compute pools alone likewise
Organism heat = the hottest of up to 656 plants	The mean, as every other organism channel; local heat stays with each plant's own reflex
Native machine pools used the HPA rule	The Cluster Autoscaler's defaults: add while work waits, remove one machine after the rest has been under 50% for 10 minutes
Building cooling sized under its own peak (native overheated half the time)	Units of 35 kW: capacity 1.25 x the declared peak

Unchanged: the plants' physics, the catalog, every other parameter, the arms, the outcomes, the guardrails, the label rule and the invalidity rules.

- **Round 2 seeds:** 2000 to 2009. Development of round 2 used seeds 0 and 1 only, never reported.
- **Results:** `results/realms/` (round 1 in `results/realms/round1/`). Both rounds are cited together.

65.11 Round 3 (2026-10-02, after round 2's results; before any round-3 counted seed)

Only the make-up of the realm organisms changes. The plants, the Omni layer, the outcomes, the guardrails, the label rule and the invalidity rules are round 2's, unchanged.

- **Round 2 cut the 656 into four realms with no overlap.** No realm organism carried the infrastructure every real stack runs on unless that infrastructure was the realm's own. The data-centre realm had no cooling or power, and the robotics and plant realms had no Kubernetes, machines or GPUs.
- **Round 3 gives every realm the shared spine** (`tools/realms_catalog.py`, SPINE): Kubernetes Workload Scaling, Placement & Scheduling, Container Resources, Node Fleet, Cloud VM & Capacity, NVIDIA GPU Hardware, Host CPU & Memory, Network Routing, Storage, Observability, Reliability & Security, Cooling & Chillers, PDU / UPS & Electrical Distribution.
  - Each realm's organism is its own families plus the spine: Compute 345 muscles, Physics 262, Energy 282, Distribution 337.
  - The whole-tower organism still holds each of the 656 once.
- **Quantum Computing Control moves to the compute realm** (it behaves as a compute job queue).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Round 3 seeds:** 3000 to 3009. Round 2 is kept in `results/realms/round2/` with a note on why it is superseded.

65.12 Round 4: the stacked organism (2026-10-02, before any round-4 seed)

The four realm organisms of round 3, stacked on one 15 s clock (`realms/harness.py`, `run_stack`; `tools/run_stack.py`). Every muscle appears as often as it appears in the realms, duplicates included: 345 + 262 + 282 + 337 = 1,226. A duplicate is still a muscle that has to converge. Each realm keeps its own internal coupling. The plants, the Omni layer, the outcomes, the guardrails and the label rule are round 3's.

- **Arms:** native (no governor); separate (one governor per realm); one (one governor over the whole stack, reading the mean of all 1,226 muscles and the stack's total power against its total budget).
- **Check, required for validity:** the stacked native run equals each realm's own native run, plant by plant, on every seed. Stacking must change nothing natively.
- **Comparisons, each labelled by the rule:**
  - one governor against native;
  - separate governors against native;
  - one governor against separate governors (does one Omni over everything beat four).
- **Seeds:** 4000 to 4009. Development used seed 0 only, never reported.

65.13 Round 5: the whole stacks with the real card inside (written 2026-10-02, before any run)

One harness (`tools/run_hil.py`, started by `scripts/gpu_rented_run.sh` after a valid card smoke): each of the six organisms (the four realms, the four stacked with every duplicate kept (1,226), the whole tower of 656) runs on one clock as in round 3, with the machine's real GPU wired in as one more muscle of its NVIDIA GPU family (a spine family, so the card is in every organism). The card serves the pinned request stream; its own power.draw is heat in the organism's thermal zones and load on its storage sites.

- **Arms:** native (the stacks' own controllers, the card's own firmware) and omni (one engine on everything: the compass law on every simulated muscle, `realms/compass_arm.py`, and on the card's two wires, `omni_controller/gpu_compass.py`). At 90% of each arm every knob and both wires are handed back; a knob not handed back, a card limit not back at its start, or a card governor exiting non-zero makes the run invalid (exit 2).
- **Seeds and repetitions:** 3 paired repetitions, seeds 6000-6002; arm order alternates by repetition and organism.
- **Clock:** 240 steps of 2 s of wall clock per arm (the card in real time).

- **Outcomes:** work per energy, work, energy and violations, Omni against native, for three parts kept apart: the simulated stacks (evidence S), the card (its own meter, evidence P), and both added (the card as one more plant, its joules added to the stacks'). Labels by the round 3 rule.

65.14 Round 6: the compute pools inside the band (2026-10-03, before any round-6 seed)

Round 3's rule (band first) was not held on the organisms: the compass law spent 0.20 to 0.29 points more time over the service line than native in every completed cell of the grid (`results/scale/GRID.md`). The cause was measured on the whole tower (seeds 7000-7003), muscle by muscle:

- **compute pools giving a machine back** (42 muscles): +1.77 points of their own time over the line;
- **the HPA target set looser than the operator's** (249 muscles): +0.22 points;
- the process and thermal setpoints, which save the most energy, added none.

Two changes, both in `realms/compass_arm.py`, everything else as round 3:

1. **The HPA target is held at the operator's own.** Loosening it past native costs the service time. This is the same rule as the card's speed floor and the live controller's cover.
2. **A machine goes back only when the machines left cover the recent peak at 0.6 of the plant's own release level** (`RELEASE_MARGIN`). A machine boots in minutes, so a burst that arrives after a release is served late until the machine is back.

How 0.6 was chosen (10 paired seeds per organism; the rule is the most work per energy whose whole interval of time over the line is at or under native): 1.0, 0.8, 0.75, 0.7, 0.65 and 0.6 on the tower; 0.65 and 0.6 on the other five.

- 0.65 failed on Physics, the upper end of its interval +0.001;
- 0.6 held on all six.

Checked on 20 paired seeds (7000-7019), before this round's official seeds:

Organism	Work per energy	Time over the line	Work done
Compute	+0.095%	−0.017 pp	unchanged within its interval (−0.001% to +0.000%)
Physics	+0.086%	−0.011 pp	unchanged within its interval (−0.001% to +0.000%)
Energy	+0.201%	−0.031 pp	unchanged within its interval (−0.001% to +0.000%)
Distribution	+0.090%	−0.015 pp	unchanged within its interval (−0.001% to +0.000%)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Organism	Work per energy	Time over the line	Work done
The four stacked	+0.153%	−0.022 pp	unchanged within its interval (−0.001% to +0.000%)
The whole tower	+0.194%	−0.010 pp	unchanged within its interval (−0.001% to +0.000%)

Every knob was handed back. The grid runs at 100× and 1,000× now on GitHub were started on round 3's law. They are recorded as round 3's result, and the grid is rerun on round 6's law.

65.15 Round 5, amended (2026-10-03, before any round-5 run on the corrected law)

The whole stacks with the real card inside run at four sizes, as the six-organism grid does: each organism as 1, 10, 100 and 1,000 copies governed together on one clock, with the one real card inside as one more muscle of its NVIDIA GPU family, native against Omni on top. Repetitions by size: 3, 3, 2 and 1 (seeds from 6000).

The step is 2 s of wall clock wherever the simulation keeps up. A size whose step takes longer gets a longer step: 1.5 times the measured time per muscle on that machine, times its muscles. The card's request stream runs for the same 240 steps, so the card and the stacks stay on one clock. The step of every size is in the receipt. At 1,000 copies the card is one muscle among hundreds of thousands, so its watts are a small share of the organism's; that is the arithmetic of one card in a large stack, and the card's own meter is reported apart from the stacks. Everything else is as round 5. The two GPU counted runs now run before this stage, so the most important results are in hand first.

65.16 Round 6 receipts and the one rule (2026-10-03)

At 1x and 10x (1,000 paired runs each) every organism is labelled superior within guardrails, with band first held and every knob handed back (`results/scale/receipts/`, `results/scale/GRID.md`). At 1,000 runs the intervals are narrow enough to show one cost: work done is lower by 0.0001% to 0.001%, wholly below zero in several organisms. Its cause was measured on the Physics organism, muscle by muscle. It is the thermal zones: a room held warmer keeps a little less margin, so a sudden heat spike puts it over its limit for a few extra seconds inside a step that already counts as over the line.

Limiting how far a room may drift (half, a quarter, none of the way toward its warm end; 40 paired seeds) does not remove it until the setpoint is held native, and then the Physics organism uses more energy than native. The cost is therefore disclosed and judged by the one rule now written for every muscle (`DISCLOSURES.md`, section 3): at most 2% in any measure, only where energy is saved. The largest work cost in the grid is 0.007% in a single run and 0.001% over 1,000 runs, far inside it.

65.16.1 The 1,000-copy size: memory and sharding (2026-10-03, before its re-run)

The first 1,000-copy run (six run 37090435347) stopped twice at the same point: every organism larger than physics and robotics ran out of memory about 3 minutes in (the four stacked at 1,000 copies is 1.2 million plants; at 33 KB a plant, and with the calibration organism built while the result organism was still held, it needed over 40 GB on a 16 GB runner). Three changes, none of which changes a number:

- the calibration run is made before the organism, so one organism is in memory at a time (`realms/harness.py`, `Body`);
- each plant is packed as it is made: its exogenous series as machine arrays, its random source dropped (every plant draws its series when it is made, never while it runs), plants with the same parameters sharing one table (`realms/plants.py`, `pack`, `_shared`);
- the six workflow sizes its shards by organism (`per_shard`, `workers` by organism), because one run of the four stacked at 1,000 copies takes 2 to 3 hours and a runner's job ends at 6.

Same outputs: four organisms, two seeds each, at 1x to 3x, byte-identical before and after. A plant now takes 6.7 KB; the four stacked at 1,000 copies needs about 9 GB. The re-run: 10 runs per organism at 1,000 copies (the 1-run and 10-run cells); 100 runs at 1,000 copies follows when the runners allow it (about 650 runner-hours).

The 100-run cells at 1,000 copies run on one rented machine (the one-machine grid script, removed on 13 October): every organism in turn, as many processes as the machine's cores and memory allow, the same seeds (7000 on), each finished organism saved at once, one receipt at the end (`SIX-1000x.md`), saved as `results/scale/v1/receipts/round6-1000x.md` in place of the 1-run and 10-run receipt it contains. From 12 October no 1,000-copy and no 1,000-run cell is started on any engine (the founder's order: 1, 10 and 100 only, the whole grid on GitHub's own machines, nothing rented for it); the rented-machine script is removed, and the cells already run at 1,000 copies stand as they were run.

65.17 Amendment (2026-10-05): the compass law is the arm, written before its run

The tables of round 3 compared native against the allocation law ("omni"), the arm that came before the compass law. The engine is now one law on everything, the compass law on top of native, so the realms runner compares native against compass (`realms/harness.py` ARMS: native, watch, compass). The watch arm stays: Omni watching must write nothing and leave every muscle exactly as native. Seeds, plants,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

knobs, guardrails and the labelling rule are unchanged. The tables published until now describe the allocation law and stay as first measured in `docs/history/`.

65.18 Amendment (2026-10-05): four levers bounded by their physics, and the mirror label (written after the compass table was seen)

Disclosed: written after the first compass-law table (nine muscles LESS WORK PER ENERGY) was seen. Each change follows from the muscle's own model (`docs/MECHANISM_OF_ACTION.md` 9.6), applies to every muscle of its kind, and is tested:

1. Cooling power is native. A cap moves heat removal later, never away, and stages more units.
2. A battery's reserve is spent only at the connection's wall, and only when the battery can cover the excess. Below the operator's reserve every kWh costs (1 - eta)/sqrt(eta) to buy back.
3. A backup reserve (the UPS preset, `backup=True`) is never a lever.
4. A compute pool's power cap moves only where (9.8) says a lower cap saves energy. A quantum computer, a network switch and storage are left native (race to idle).

The labelling rule gains the mirror of ENERGY IMPROVEMENT WITH SERVICE TRADEOFF: less work per energy, no work lost (at most 1%), and the time over the line proven lower is SERVICE IMPROVEMENT WITH ENERGY TRADEOFF. Everything else is as before, and every other label keeps its definition.

Also in this amendment: an effort cap on a motion axis moves only where the copper loss it saves at full acceleration, (J a[max] / kt)^2 R, exceeds the standing draw a longer move pays, p[idle] + b v[max]^2 (a reaction wheel; not traction, a flight axis or a robot joint). The machine-release margin on node pools is 0.3, the largest at which no pool is later than native (`results/realms/RELEASE_MARGIN_SWEEP.md`, the per-muscle sweep).

65.19 Omni v2: the catalog grows to 945 muscles in 59 families (2026-10-06, before any v2 seed)

Written before any counted v2 run. **The law, the controllers, the plants, the Omni layer, the outcomes, the guardrails, the label rule and the invalidity rules are v1's, byte for byte.** Only the catalog and the presets it needs change, so by the change rule of `docs/OMNI_V1.md` this is a new version, Omni v2 (`OMNI_V2.json`, `docs/OMNI_V2.md`), and every modelled result is run again on it. No v1 result is read as a v2 result.

What is added, each row with its real system, its setting and its source, built by `tools/realms_catalog_v2.py` from three committed files by the v1 rules (realm, membership, plant, preset and knob: `tools/realms_catalog.py`, unchanged):

- **The 656 of v1, byte for byte** (`realms/catalog_v1.csv`): every v1 muscle keeps its id, realm, plant, preset and knob.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **118 real controls the realm study had already found and the tower lacked** (`docs/realm_study/TRUE_MUSCLES.csv`, the rows marked "added (real, not in the 656)"; six of them were already in the tower under another name and are listed as skipped in `realms/catalog_provenance.json`). They join the family the study filed them under; 70 of them are spine muscles (Kubernetes, nodes, hosts, GPUs, storage, network, observability, power, cooling) and so sit in all four realms.
- **171 muscles in thirteen new families** (`realms/wave4_families.csv`), the domains the tower did not cover, one new preset each (`realms/presets.py`, round engineering figures for the class of machine, as every other preset):

Family	Realm	Plant / preset	Muscles	Examples of the real system
Healthcare Critical Environments	Energy / Facility / Industrial	thermal_zone / hospital	13	ASHRAE 170 rooms on a hospital BMS (Metasys, Desigo); isolation-room pressure; pharmacy cold rooms
Medical Imaging & Clinical Systems	Distribution / Specialized	compute_pool / clinical	12	DICOM archives and routers (Orthanc, dcm4chee), EHR tiers, HL7/FHIR engines, monitoring gateways
Agriculture & Irrigation	Energy / Facility / Industrial	process_loop / irrigation	14	pivot and pump controllers (Valley, Lindsay, Netafim), greenhouse climate computers (Priva), grain dryers
Oil & Gas Pipelines	Energy / Facility / Industrial	process_loop / pipeline	14	compressor and pump station SCADA (Emerson, AVEVA, Honeywell), API 1130 leak detection, DRA injection
Rail Traction & Train Control	Physics / Robotics / Autonomous	motion_axis / rail_traction	14	traction converters and ATO (Siemens Mobility, Alstom, Hitachi Rail), CBTC headway, ERTMS
Marine Propulsion & Vessel Automation	Physics / Robotics / Autonomous	motion_axis / marine_propulsion	12	propulsion and power management (Kongsberg, Wärtsilä, MAN), IMO shaft power limitation

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Family	Realm	Plant / preset	Muscles	Examples of the real system
Ports & Maritime Logistics	Distribution / Specialized	compute_pool / port	12	terminal operating systems (Navis N4), automated cranes and AGVs (Kalmar, Konecranes), shore power
Mining & Mineral Processing	Energy / Facility / Industrial	process_loop / mill	14	grinding and flotation control (Metso, FLSmidth, ABB), ventilation on demand (Howden), dewatering
District Heating & Cooling	Energy / Facility / Industrial	process_loop / district_heat	13	network and substation control (Danfoss Leanheat, Kamstrup), CHP dispatch, thermal storage
Power Generation & Turbine Control	Energy / Facility / Industrial	process_loop / turbine	14	governors and plant DCS (GE Mark VIe, Emerson Ovation, Woodward), AVRs, hydro gates, reactor rods
Renewable Generation & Inverter Control	Energy / Facility / Industrial	process_loop / inverter	13	IEEE 1547 inverter curves (SMA, Enphase), wake steering (NREL FLORIS), pitch and curtailment (Vestas)
Elevators & Vertical Transport	Physics / Robotics / Autonomous	motion_axis / elevator_hoist	12	drives and destination dispatch (Otis, KONE, Schindler), ISO 25745 standby modes
Pharmaceutical & Food Manufacturing	Energy / Facility / Industrial	process_loop / batch_reactor	14	ISA-88 batch control (DeltaV, SIMATIC Batch), bioreactors (Sartorius), pasteurizers, CIP, cleanrooms

Four wave-4 names collided with the tower and carry a domain prefix (`terminal_tank_level_target`, `train_auxiliary_power_budget`, `plant_reactive_power_target`, `inverter_frequency_droop_setpoint`). Eleven names the knob rules would have placed wrongly are set by hand in `tools/realms_catalog.py` OVERRIDE and listed there.

The organisms of v2: Compute / AI / Cloud 430, Physics / Robotics / Autonomous 376, Energy / Facility / Industrial 470, Distribution / Specialized 440, the four stacked 1,716, the whole tower 945; the shared spine is 257 muscles. In code and workflows the two whole-tower organisms are now named `tower` and `stack`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(nothing is named by a count); the v1 names `organism_656` and `stack_1226` are read as aliases, so every v1 run folder and record still reads.

Checked before this freeze, on seed 7, every one of the 289 added muscles: deterministic, the watch arm equal to native, every knob handed back after the kill, no number undefined, Omni's time over the line never above native's. Two presets were adjusted on that check and before any counted run: the inverter plant's disturbance amplitude (0.8 to 0.5, with its noise 0.05 to 0.02) because native itself was outside its band a quarter of the time, and the elevator hoist's position gains (kp 2,000 to 3,000, kd 400 to 500) with a smaller load disturbance (400 to 100 N m), because the first figures put native's tracking error at its limit under passenger load. Where native is still often outside its band in some heavy-load muscles (the compute pools at their busiest sizes), that is the plant at the size the muscle id draws, the same for both arms, and it is reported as it comes.

v2 runs: the realms table (every muscle alone and the five organisms, seeds 3000-3009, three GitHub runs A, B, C), the six-organism grid at 1, 10, 100 and 1,000 copies, the six organisms with the real cluster inside, and the big organisms on Azure, each on the v2 fingerprint; the live benchmarks that import none of the realm files (Kubernetes alone, Azure alone, CityLearn, the grid, the robots, the database) are run again on v2 as GitHub's queue allows, their v1 tables kept as v1 tables.

65.20 Omni v3: the slack gate on speed knobs (2026-10-06, after the v2 table, before any v3 seed)

Declared on the v2 result and before any v3 run. The v2 table (`results/realms/REALMS.md`, three runs reproduced) read Physics and the whole tower as "energy improvement with a service tradeoff" where v1 had every organism superior. The rows that carried it were the new speed muscles: three rail traction muscles where Omni's slowing added 1.6 to 2.7 points of lateness on a train already near its timetable's capacity, and two marine and two elevator muscles where the slower cycle finished fewer moves in the hour. By the honesty rule the first suspect was our own wiring, and it was: the realm harness had no do-no-harm gate on the speed knob of a motion axis, so the compass slowed an axis that had no slack to spend. The robot benchmark has such a gate (its paired physics trial, `docs/ROBOTICS_PREREGISTRATION.md`); the realms get one now.

The rule (`realms/compass_arm.py`, `speed_slack`). A motion axis is offered its speed knob only where its duty at full speed, task rate × (move time at full speed + dwell), is at most SLACK = 0.5, computed from the plant's own figures before any decision. The compass may ease an axis down to 0.4 of its speed, which stretches a move by up to 2.5 times; an axis busy more than half the time at full speed cannot absorb that when tasks arrive in bunches, and its knob stays native. Where the knob is offered, nothing else changes: the compass, its gains, the cover [0.4, 1.0] and the fail-up are v2's.

The marine preset. Four 600 rad speed changes an hour made a one-hour run too coarse to count (one unfinished move is a quarter of the hour's work); the v3 preset is twelve changes of 200 rad an hour, a move of 126 s plus 30 s of dwell, deadline 1,200 s. No other preset changes.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

What the gate does on the shipped presets (the middle size; a muscle's own size, 0.6 to 1.4 on the task rate, moves its duty either side):

Preset	Move at full speed	Dwell	A task every	Duty	The speed knob
flight axis	4.8 s	2.0 s	20 s	0.34	offered
reaction wheel	30.0 s	5.0 s	100 s	0.35	offered
marine propulsion	126.5 s	30 s	300 s	0.52	left native
elevator hoist	12.8 s	8.0 s	40 s	0.52	left native
robot joint	0.7 s	0.2 s	1.7 s	0.54	left native at the middle size, offered on the lightly loaded joints
EV traction	35.6 s	10 s	60 s	0.76	left native
rail traction	220 s	20 s	300 s	0.80	left native

The threshold is a declared number set on the v2 finding, not a fitted one: it is written here before the v3 runs and applies to every axis alike. Where it leaves a knob native the row will read as native does, and that is the result. Everything else, the plants, the outcomes, the guardrails, the label rule and the invalidity rules, is v2's. v3 runs the realms table three times (A, B, C), then the grid, then the organisms with the real cluster inside; the v2 table stays a v2 result.

65.21 Amendment (2026-10-16): the spine, the seventh organism (written before its run)

The founder's order of 16 October: the **spine** is an organism in its own right. It is the set of catalog muscles whose realm list names all four realms, 267 of the 1,107 (`tools/run_realms_v5.py`, `spine_rows`), in thirteen families: Kubernetes workload scaling, container resources, placement and scheduling, node fleets, cloud capacity, host CPU and memory, GPU hardware, network, storage, observability, reliability and security, electrical distribution, cooling. Run alone it is a data center with nothing of any one trade in it, the base every stack runs on (`docs/THE_SPINE.md`).

- The spine runs as the seventh organism in every organism harness, under the same three loads (its own, the climb, work waiting in line), the same seeds (3000-3009 preregistered), the same two arms (native; Omni-Compass on top of native) and the same label rule as the other six; every table lists it first. In `tools/run_scale.py` and the grid conductor it is organism 7, so every grid run already started reads back under its own number; with the real cluster inside it is `tools/run_kil.py --organism spine`.
- The organisms are groupings of catalog rows made in the runners. No engine file changes: the fingerprint (`python3 tools/omni_version.py`) is the same before and after, and the six organisms' results

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

on the engine that stands are unchanged by the seventh (the run is deterministic on its seeds; the rerun that adds the spine's rows reproduces theirs to the digit, checked by `realms-v5.yml`).

- Nothing is read across engines: the spine's rows carry the engine they ran on, like every other row.

CHAPTER 66

The Compass Law on Real Kubernetes: Preregistration

Written and committed before the run. The run's commit is the one that carries this file; nothing in the law, the harness or this rule changes after it starts.

66.1 What is run

Workflow `benchmark-reps` on `main`, 10 repetitions. Each repetition runs three arms back to back on the same runner, each on a fresh six-worker kind cluster, in an order rotated by repetition (`scripts/kind_paired.sh`):

Arm	What governs
native	Kubernetes alone (HPA at target 50, scheduler); Omni-Compass not started
omni	Omni-Compass on top with the engine's allocation law (`--law governor`, the law of sets 22 to 25)
compass	Omni-Compass on top with the compass law (`--law compass`, `omni_controller/controller.py`)

Load: fixed rate (`loadgen=open`), the same work in every arm. 900 measured seconds per arm. SLO 500 ms at the 95th percentile. Every Omni arm runs the six-state engine on every decision, the nervous system's authority and release gate, the shield, the compass, and ends with the reset, which must return the HPA target, its replica range, the pods' CPU limits and every worker to native, with no record left (`scripts/kind_bench.sh`).

66.2 The compass law in the live controller

The service position is the 95th-percentile response time over the SLO (0 calm, 1 the line); a blind probe or a pod waiting for a place reads as past the wall. The force is `A tanh((K_P (p - 0.5) + K_D v) / A)` with K[D] for critical damping times the realm push factor 3, the same law and gains as on every realm muscle (`realms/compass_arm.py`): up gain 0.10, down gain 0.02, release threshold -0.2. Two levers:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

1. **HPA target**, cover from 60% of the operator's target to the operator's own: the up force lowers it (more pods), the down force returns it toward the operator's. It is never tighter than native.
2. **Node pool**: past the 0.95 wall one machine more at once; one machine back only while the force is below -0.2, the position is below the center, and the nervous system's release gate is open.

66.3 Outcomes and the rule

Primary: **worker nodes in service** (mean) and **95th-percentile response time**, each arm against native, paired over the 10 repetitions with a t-based 95% interval (`tools/live_reps.py`).

Band first: the compass arm is a win only if its p95 is not behind native's (the upper end of the 95% interval of the paired difference at or under 0) **and** failed requests are not higher. If that holds and machines in service fall with an interval wholly below 0, the label is **fewer machines within the band**. If machines fall but the band condition fails, the label is **tradeoff**. Otherwise **not established**.

Secondary, reported, not used for the label: p99, mean response time, HPA replicas, pods started, pod start wait, CPU including Omni-Compass's own, the declared energy models. The omni arm is reported against native and against the compass arm by the same rule. A run that fails its own checks (reset, controller stopped early, missing permission) is marked invalid and left out, never silently counted.

Evidence class **L**: real Kubernetes software on kind. Energy on kind is a declared model, not a meter.

66.4 Set 26 result

Compass arm against native: machines in service -17.2% (-26.4% to -7.9% of native), p95 -64.8%, failed requests 0 on both: **fewer machines within the band** (`results/live/LIVE_REPS_26.md`). The allocation law in the same set: machines -35.8%, p95 -55.4%.

66.5 Set 27 (written before the run)

The compass in the live controller now reads the service as the GPU compass does (`omni_controller/gpu_compass.py`, GPU amendments 6 and 7): the mean response time of the latency window between the bare service time (a tenth of the SLO) and the SLO, held at the compass's center 0.4 (the GPU service profile); p95 at or past the SLO, a blind probe or a pod waiting for a place is past the wall. Everything else, the arms (native, omni, compass), the load, the duration, the outcomes and the labelling rule above, is unchanged. The run's commit is the one that carries this section.

66.6 Set 27 result

Compass arm, aligned with the GPU governor, against native: machines in service -15.9% (-1.462 to -0.450 machines), p95 -65.5% (-311.8 to -156.1 ms), p99 -72.6%, failed requests 0 on both: **fewer machines within the band** (`results/live/LIVE_REPS_27.md`, run 37071353971, commit `d46c959`). The allocation law in the same set: machines -36.6%, p95 -53.1%.

All patents, copyrights and trademarks filed in the USA.

66.7 The verdict in the live controller (2026-10-03, before any further set)

The compass law gives a machine back only where it measures that the service is never behind for it (`omnicompass/verdict.py`, stepwise, in `omni_controller/controller.py`). While the service is calm (inside the compass, no pod waiting, no breach), one more machine is given back on trial. The response times of 200 requests served without it are set against 200 served just before and against the cluster as it first ran on its own:

- at most 2% slower than both: the machine stays given back;
- slower than that: it is taken back and not tried again for 120 decisions.

Where no machine passes, the pool stays as the cluster runs it alone. The HPA target's cover is unchanged: from 60% of the operator's target up to the operator's own, never looser than native. Every trial is in the audit. The next set runs with this verdict; sets 26 and 27 ran before it and stay as they ran.

66.8 Set 28 and set 29 (2026-10-03, set 29 written before its run)

Set 28 (run 37087620193, commit `24666d7`) ran the compass law with the verdict. With Omni-Compass on top against native:

- machines in service −4.7%;
- p95 −65.3%, p99 −68.6%;
- pods waiting 0;
- failed requests 0.

Total CPU including Omni-Compass's own came out **+2.2%** (+0.003 to +0.042 cores), more than the 2% the one rule allows (`DISCLOSURES.md`, section 3). The cause is the controller's own cost: 0.063 cores, mostly a new kubectl process for every read, about 20 a minute. The compass law with the verdict freed only 0.040 cores of work. The allocation law in the same set: machines −29.6%, p95 −58.0%, total CPU including its own −1.2% (not significant). Set 28's receipt is `results/live/LIVE_REPS_28.md`, published with this section.

Set 29 runs the same arms, load, duration, outcomes and rule as set 28. One thing changes: the controller reads through one `kubectl proxy` started once, under the same least-privilege identity, so a read is a local HTTP request instead of a new kubectl process (`omni_controller/controller.py`, `Kube`; writes are unchanged; `tests/test_api_proxy.py`). The label also requires total CPU including Omni-Compass's own to be no more than 2% above native.

Set 29 result (run 37094338955, commit `a3721cc`): the compass law with the verdict, total CPU including its own **−4.7%** (−0.071 to −0.017 cores), passes; Omni-Compass's own CPU 0.011 cores (set 28: 0.063). Machines −5.1%, p95 −64.4%, p99 −71.1%, HPA replicas −7.6%, failed requests 0. No measure significantly behind native in either arm. Receipt: `results/live/LIVE_REPS_29.md`.

66.9 The cost to match (written before its run)

The question a buyer asks: what would native Kubernetes have to spend to answer as fast as it does with Omni-Compass on top? Each repetition runs, on the same runner and the same work, in rotated order:

- native (the operator's HPA target 50);
- native tuned harder by its operator, HPA target 40, 30 and 20 (more pods, faster answers), no Omni-Compass (`ARM=native40`, `native30`, `native20` in `scripts/kind_bench.sh`);
- native with Omni-Compass on top, the allocation law (`omni`);
- native with Omni-Compass on top, the compass law with the verdict (`compass`).

The report (`tools/live_reps.py`, "The cost to match") lists every arm's p95, p99, HPA replicas, CPU including Omni-Compass's own, and machines in service. For each Omni-Compass arm it names the cheapest native setting (by CPU) whose p95 is at or under Omni-Compass's, and that setting's extra replicas, CPU and machines over Omni-Compass. If no native setting tried reaches it, the report says so and gives the lowest native p95. 10 repetitions, 900 measured seconds per arm, fixed-rate load.

66.10 The fault test (written before its run)

Health, security and the babysitting a cluster needs, measured. Every arm (native; native with Omni-Compass on top, the allocation law; native with Omni-Compass on top, the compass law with the verdict) meets the same four faults at the same moments (`scripts/kind_faults.sh`, `FAULTS=1`):

1. at 15% of the run, a worker machine dies (its kind container is stopped) and comes back two minutes later;
2. at 35%, traffic triples for two minutes;
3. at 55%, a pod with no CPU limit burns CPU for two minutes;
4. at 75%, the response-time probe goes blind for one minute.

For each fault the report (`tools/live_reps.py`, "The fault test") gives the time to recover (from the fault's start until responses stay under the line for 30 s straight, at most 300 s) and the share of samples over the line or failed in the 300 s after it, paired against native over 10 repetitions. All the usual gauges are reported as well, now including the share of response samples over the line (`pilot/bench_report.py`). The aim is lower in each.

The fault test, first run (run 37094604580, commit `a149d4e`; `results/live/FAULTS.md`). Omni-Compass on top recovered faster than native from every fault (allocation law: machine down −29%, runaway pod −35%, spike −7%; compass law: −14%, −17%, −6%), p95 −53% and −55%, p99 −27% (not significant) and −57%. One measure read LOSS: with the compass law, **HPA replicas +8.2%** (+0.41 to +0.99, significant), with CPU and machines unchanged and no energy saved, so outside the one rule (`DISCLOSURES.md`, section 3). The cause: past the wall the compass lowers the HPA target at once (more

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

pods, the faster recovery), then handed the operator's target back step by step and held each step for the autoscaler's window, so the extra pods outlived the fault.

The change, written before the re-run (`omni_controller/controller.py`, the compass's push and pull on the HPA target; `tests/test_compass_controller.py`, "fault over"): once the responses are back inside the band (the compass's position under its center), the response line is clean and no pod is waiting, the operator's own target returns at once and is not held by the window. More pods only while the fault lasts. The re-run is the same fault test, arms, load, duration and rule (set 30 F); set 30 runs the same code without faults, to show nothing else moved.

Set 30 and set 30 F (runs 37105047258 and 37105046042, commit `acc1c4e`; `results/live/LIVE_REPS_30.md`, `results/live/FAULTS_30.md`). Set 30, no faults: no LOSS clear of the noise in either arm; the compass law's machines −9.9%, p95 −64.9%, time over the line −98.7%, HPA replicas −32.2%, total CPU −6.5%. Set 30 F: recovery faster than native from every fault in both arms; the compass law's HPA replicas **+5.6%** (first run +8.2%), still significant, with CPU and machines unchanged. The allocation law, which recovers as fast or faster, held no extra pods (+2.0%, not significant).

The second change, written before set 31 F (`omni_controller/controller.py`; `tests/test_compass_controller.py`, "blind"). Past the wall, the compass lowers the HPA target (more pods) only when the cause is load: the response line breached with every sense live and no pod waiting. Past the wall from a blind sense, or from pods waiting for a machine that is gone, more pods answer neither, so the target is the operator's own: fail up is native's own setting, as on the card, where fail up is the card's own clock and limit. The machine reflex (one machine more past the wall) is unchanged. Set 31 F is the same fault test, arms, load, duration and rule; set 31 the same without faults.

Set 31 and set 31 F (runs 37110007121 and 37110005322, commit `0a38e76`; `results/live/LIVE_REPS_31.md`, `results/live/FAULTS_31.md`). Set 31 F: the compass law's HPA replicas under faults **−1.1%** (not significant): the extra pods are gone. No LOSS clear of the noise in either arm; recovery faster than native from every fault (compass law, machine down −49%). Set 31: no LOSS clear of the noise; the compass law's machines −10.4%, p95 −66.0%, p99 −73.0%, time over the line −99.4%, HPA replicas −44.5%, pods started 0 against native's 4.3, total CPU −6.1%.

66.11 The bill on a real cloud (written before its run)

The question a buyer pays for: the same work, a smaller bill? On kind every machine stays powered, so a machine given back saves only a declared model's energy. On a real cloud the machine is deleted and stops being billed. The run (`.github/workflows/aks-metered.yml`, `scripts/aks_paired.sh`, `scripts/kind_bench.sh` with `PLATFORM=aks`):

- **The cluster.** Azure Kubernetes Service, a fresh cluster for every arm, built the same way:
  - a system pool of one machine, tainted so no workload lands on it (AKS's add-ons and the load generator: kind's control plane);

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

    - a work pool starting at 4 machines (Standard_D2s_v5) under **Azure's own cluster autoscaler** (min 1, max 4; scale down after 2 minutes unneeded), which deletes a machine once it is empty.
- **The arms**, rotated in each repetition:
    - native: Kubernetes with Azure's autoscaler alone;
    - native with Omni-Compass on top, the compass law with the verdict (`compass`);
    - native with Omni-Compass on top, the allocation law (`omni`).

With Omni-Compass on top, the machines it gives back are idled (new pods go elsewhere, their pods leave first), and Azure's autoscaler then deletes them. Omni-Compass never deletes a machine itself.

- **The same work** in every arm: the fixed-rate load of sets 22 onward, 900 measured seconds after 120 s of warm-up.
- **The bill.** Every 15 s, the number of work machines that exist (in service or idle, every one is billed), integrated over the measured window: billed machine-hours, priced at Azure's list price for the machine (USD 0.096 an hour for Standard_D2s_v5, Linux, pay as you go, set in the workflow's input). Omni-Compass never reads this count.
- **Outcomes.** Billed machine-hours and the bill (the aim is lower), and every gauge of sets 28 and 29 (response time, failures, pods waiting, CPU including Omni-Compass's own), paired against native with 95% intervals over 5 repetitions. Labelled by the one rule (`DISCLOSURES.md`, section 3): no LOSS of more than 2%, and only where the bill or energy is saved.
- **Housekeeping.** One repetition at a time; each cluster deleted when its arm ends, before the next is made; the resource group deleted at the end of every repetition whatever happens. It needs the repository secret `AZURE_CREDENTIALS`.

66.12 The capacity test (written before its run)

The question behind "more work for the same cost": on the same machines, how much more work does Kubernetes serve with Omni-Compass on top before its answers break the line? Each repetition runs native, native with Omni-Compass on top (the allocation law) and with the compass law and the verdict, in rotated order, on the same six workers, the open-loop load rising in eight equal steps of one load generator each (6 requests a second per generator, 1 to 8 generators, 200 s a step, 1,600 measured seconds; `load_steps` in `benchmark-reps`). A run's capacity is the highest step at which no more than 5% of the response samples (every 5 s, through the Service) are over the line (500 ms) or failed, every lower step holding too, the first 30 s of each step left to settle (`tools/live_reps.py`, `capacity`). Reported: each arm's mean capacity in requests a second, its change against native and the 95% interval of the paired difference over 10 repetitions; every usual gauge beside it. Labelled by the one rule: no LOSS of more than 2%.

All patents, copyrights and trademarks filed in the USA.

66.13 The fairness test (written before its run)

The question a buyer with many tenants asks: when one application surges, does Omni-Compass on top protect its neighbour, or starve it? Each repetition runs native, native with Omni-Compass on top (the allocation law) and with the compass law and the verdict, in rotated order, on the same six workers, with two applications on them (`TWO_APP=1`, `deploy/kind/noisy.yaml`): php-apache under its usual fixed-rate load, and a noisy neighbour, the same image and the same HPA rule, whose own fixed-rate load surges in steps (0, 0, 6, 0, 6, 0 load generators of 6 requests a second, the same moments in every arm). Each application's response time is probed through its own Service. Omni-Compass governs both HPAs (`deploy/kind/rbac-omni-noisy.yaml`: the second HPA and nothing else more). Reported: every usual gauge for php-apache, and the neighbour's p95, p99, time over the line and failed requests, each paired against native over 10 repetitions with its 95% interval. The label is the one rule, applied to both applications: no LOSS of more than 2% for either.

66.14 The capacity and fairness results, and the amendment they call for (2026-10-03 evening, before either is run again)

Capacity (`results/live/CAPACITY.md`, run 37150909816): the compass law served 33.0 requests a second within the line against native's 24.6, **+34.1% (95% interval of the paired difference +6.2 to +10.6 requests a second)**, with response times about half of native's and fewer failures. One measure significantly LOSS: pods started 7.3 against 5.6 (+30.4%) while the mean HPA replicas were 26.9% lower: churn, not more pods. **Fairness** (`results/live/FAIRNESS.md`, run 37154210570): the neighbour unharmed under both laws; with the compass law php-apache's failed requests 3.89% to 4.90% (+0.12 to +1.90 points), pending pods and pod start wait higher, no machine saved. By the one rule neither result is labelled GAIN. Both causes are read from the controller's code; both corrections are stated here, as law, before the tests run again.

1. Only a sensed muscle moves (the fairness cause). Let the probe measure the response time of the services in a set S (`--sensed ns/deployment,...`; empty means every HPA, the single-service case). For each HPA h scaling a deployment d(h) with the operator's target $x^{(op)}_h$, the target written is

$x_h(t)$ = the compass's (or the allocation law's) target, if $d(h) \in S$; $x^{(op)}_h$, if $d(h) \notin S$

The probe's position p is a statement about S alone. A push on a muscle outside S answers no sensed error and adds pods that compete with S for the same machines (the run's pending pods and failures). It is the GPU law's own rule, applied to Kubernetes: where Omni-Compass cannot sense, it stands at native's own setting.

2. Pods owed to a growing demand stay (the churn cause). Let u(t) be the CPU the workers use and W the HPA's scale-down window (W = 300 s unless the operator set one). The demand is *still growing* when

$G(t) = [u(t) > (1 + \varepsilon) \min[t - W \le s \le t] u(s)]$, $\varepsilon = 0.05$.

After a breach the compass lowers the target to the bottom of its cover, $x = x[lo] = 0.6\ x^{(op)}$ (more pods, at once). Before this amendment, the first decision with the position back under the centre, $p < c = 0.4$, no breach

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

and no pod waiting, returned x = x^(op) at once. Under a rising load the autoscaler then removed the extra pods one window later and started them again at the next step: the run's churn. The return is now

x ← x^(op) only if p < c, no breach, no pod waiting, ¬ G(t),

and while G(t) holds the target stays where the breach put it. A fault or a spike that has passed has a flat or falling u, so G is false and the operator's target returns at once, as the fault test requires (set 31 F: HPA replicas under faults −1.1%); only a demand still climbing keeps its pods. ε = 0.05 is set above the decision-to-decision noise of the node CPU reading. A rise too small to clear it leaves the rule as it was before this amendment (the target returns at once), so the correction can remove churn but cannot add any.

Nothing else changes: the compass's band, gains and centre, the verdict, the fail-up rules, the release gate and the node-pool law are as registered. Tests: `tests/test_compass_controller.py`, cases *demand* and *sensed*, beside the existing *fault over*, *blind* and reset cases.

The re-runs, on the commit that carries this amendment, unchanged in design: the capacity test (`load_steps` 1 to 8, 1,600 s), the fairness test (`two_app` 1, 900 s) and the fault test (`faults` 1, 900 s), 10 paired repetitions each, arms native / omni / compass. The second application is now probed and reported as before, and its HPA is held at the operator's target. Labelled by the one rule. Every number, whatever it says, is published beside the runs above.

66.15 The re-runs under the amendment: results (2026-10-04)

All three on commit `199f350`, 10 paired repetitions each, the design unchanged.

- **Fault test, set 32 F** (`results/live/FAULTS_32.md`, run 37162459956): **no LOSS clear of the noise under either law.** The compass law recovers from a lost machine 58% faster and starts 34% fewer pods; the amendment left the fault behaviour of set 31 F intact.
- **Fairness** (`results/live/FAIRNESS_2.md`, run 37162458834): **correction 1 holds.** With the compass law php-apache's failed requests are no longer lower (−14.0%, not significant; before +26.0%), pending pods −10.5% (before +65.2%); the neighbour unharmed under both laws. The compass law's response-time gains in this test are no longer significant. Still higher under both laws: the mean pod start wait (+1.1 s compass, +1.7 s allocation law).
- **Capacity** (`results/live/CAPACITY_2.md`, run 37162457542): the compass law served **24.6 against native's 16.2 requests a second, +51.9% (+6.2 to +10.6)**, the same paired difference as the first run on slower runners; response times −28% to −56%, failures −9.6%, HPA replicas −10.7%. **Correction 2 did not remove the extra pod starts** (5.1 against 3.8, +34.2%; before +30.4%): its premise, that the extra starts were pods removed and started again between steps, is not borne out. With the mean replicas lower, the reading the data support is pods started earlier on a rising load, the mechanism of the added capacity. Correction 2 stays (it removes no gain and added no measure power given); the pod-start rows stand as measured, and by the one rule neither the capacity nor the fairness arm is labelled GAIN while they do.

All patents, copyrights and trademarks filed in the USA.

66.16 The pod record, and the second amendment (2026-10-04, before the next runs)

What the pod record shows (`tools/pod_report.py`, workflow `pod-report`, read from the stored artifacts of runs 37162457542 and 37162458834; nothing re-run). In the capacity test native started its pods once, early (33 of 38 in the first fifth of the window), and removed none. With Omni-Compass on top, two minutes into the window the controller raised the HPA target above the operator's (the conveyance: each pod given a larger CPU limit, the target raised by the same factor so each pod stays as busy, x = g x^(op); 114% with the compass law, 190% with the allocation law). The autoscaler then removed pods (14 with the compass law, 35 with the allocation law, over ten repetitions), and the next load steps started them again. **The extra starts are exactly those removals.** Correction 2 above read the wrong signal: the CPU used by the whole node, where one load step is lost in the node's own load.

3. A raise of the target waits for a steady demand. Let the demand on an HPA's service be read from the autoscaler's own status, D(t) = ū(t) r(t): the pods' mean CPU utilisation of their request times the pods running, the CPU used in units of one pod's request. With W the HPA's scale-down window and ε = 0.05,

$S(t) = [t - t_0 \geq 0.9\,W \wedge \max[[t-W, t]]\, D \leq (1+\varepsilon)\min[[t-W, t]]\, D]$

(t_0 the oldest sample in the window). A new target above the one standing (fewer, larger pods) is written only when S(t) holds; the autoscaler itself removes pods only after its scale-down window, and Omni-Compass now asks the same of its own consolidation. A lower target (more pods) is never held, and the return of the operator's own target after a fault (rule 2) is unchanged. Correction 2's growth test G(t) now reads the same D(t) of the HPA concerned, not the node's CPU. Tests: `tests/test_compass_controller.py`, case *steady*.

The capacity, fairness and fault tests are run again on the commit that carries this amendment, unchanged in design, and published beside the runs above whatever they show. The bill run on Azure (`aks-metered`, run 37171672509) started on commit `199f350`, before this amendment, and is reported as of that commit.

66.17 The third amendment, and a change considered and declined (2026-10-04, before the next runs)

4. A lower target is never held. Until now every new HPA target, in either direction, was held for one autoscaler window W while the line was clean, so on a step up the compass's push (a lower target, more pods) could wait up to W and the pods arrive after the line is missed. The hold exists because a raise inside the window removes pods the autoscaler then starts again; a lower target asks for pods and removes none. The hold now applies to raises only:

write $x_h(t) \Leftrightarrow x_h(t) < x_h\hat{}(\text{now})$ ∨ no write in [t−W, t) ∨ the operator's own target returns,

with rule 3 still requiring a steady demand before any raise. Tests: `tests/test_convey.py` (a lower target written at once inside the window).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Declined: raising the replica cap above the operator's. `deploy/kind/demo.yaml` sets `maxReplicas: 10`, and at the top of the capacity test both arms meet it. Lifting it would let Omni-Compass run more pods than the operator authorised, which is more resources, not the same resources doing more, and it would break the shield's standing rule that Omni-Compass never moves past an operator's bound. Native would need the same cap for the comparison to stay fair. It stays at the operator's value in every arm; a higher cap is the operator's decision, tested as its own setting if ever asked for. Already in place and unchanged: a pod waiting for a place reads as past the wall and asks for one machine more at once.

A narrower form was proposed the same day (`docs/history/AMENDMENT_RISING_STEP_CAP.md`): while the demand rises and a pod of the sensed service is pending, raise `maxReplicas` by the pending count and lower the target to match. It is declined for a mechanical reason as well as the one above. The replica cap does not make pods pending: at the cap the autoscaler simply asks for no more pods, so the pending count there is zero and the write would never fire where it is aimed. A pod is pending only when the scheduler finds no machine with room for it, and more places under the cap give such a pod nowhere more to go; the answer to that is a machine, which the compass already asks for. The part of the proposal that holds, asking for pods at once on a step up instead of after a window, is rule 4 above.

On the CPU fill (used over allocatable about 0.10 in every arm): on kind every worker reports all of the host's cores as its own, so the allocatable counts the same cores once per worker and the fill reads far lower than the machine doing the work. Every receipt from the next runs on carries the host's own busy share and core count (`host_cpu.csv`, `tools/live_reps.py`), so the room left on the real machine is measured, not inferred.

The capacity, fairness and fault tests are run again on the commit that carries this amendment, beside the runs of commit `5d2e238` (rule 3 alone), so each rule's effect stays separable.

66.18 The second amendment's runs: results (2026-10-04)

`results/live/AMENDMENT_2_RUNS.md`, commit `5d2e238` (rule 3 alone), 10 paired repetitions each.

- **Capacity: no LOSS clear of the noise under either law.** Compass law 24.6 against native's 17.4 requests a second, +41.4% (+5.4 to +9.0); allocation law 25.2, +44.8% (+4.9 to +10.7). The compass law's pods started 5.7 against 4.1, interval −0.64 to +3.84: no longer significant. Rule 3 removed the significant pod-start excess and lifted the allocation law's capacity from +0.0% to +44.8%.
- **Faults: no LOSS clear of the noise under either law.**
- **Fairness: the compass law, no LOSS clear of the noise for either application.** The allocation law: php-apache much lower, and the neighbour's failed requests **+0.74 points (+0.19 to +1.28), significant**. The allocation law conveys idle CPU to the service it senses; on machines shared with a surging neighbour that CPU is the neighbour's headroom. The allocation law is not labelled GAIN in this test.

Standing after rule 3: the compass law is clean in all three tests (no LOSS clear of the noise, capacity +41.4%). Rule 4 (a lower target never held) runs next on commit `583c97f`, beside these, to see whether it adds capacity without costing a row.

All patents, copyrights and trademarks filed in the USA.

66.19 The fourth amendment: the replica cap as a lever the operator grants (2026-10-04, before its run)

The founder's instruction: no number in the harness is hard-wired; every one moves where the system lets it. The cap of 10 in `deploy/kind/demo.yaml` is the value of Kubernetes' own php-apache example, not a choice of any operator, and an earlier session read it as an operator's bound. It becomes a lever, under the operator's grant.

5. Replica room. With `--replica-ceiling` N[max] granted (0, the default, leaves the cap untouched), for a sensed HPA under the compass law, with r the pods running, c the cap, $\bar{u}$ the pods' mean utilisation and x the target, the autoscaler's own arithmetic asks for $n = \lceil r\,\bar{u}/x \rceil$ replicas, and

$c \leftarrow \min(N[max], n)$ if $r \geq c$, $n > c$, $p \geq$ centre or the line is breached; $c \leftarrow c^{(op)}$ if $n \leq c^{(op)}$, $p <$ centre, no breach, S(t).

The cap is raised only while it binds and the line is threatened, to what the autoscaler asks and never past the grant, and returns to the operator's once the demand has held still for a window. The operator's range is recorded before the first change; the reset restores it. Tests: `tests/test_compass_controller.py`, case *room*.

Its run (a setting of its own, labelled as such): the capacity test unchanged, `replica_ceiling` 30, beside the runs without it. Native keeps its cap of 10, as an operator who has not raised it would; the extra pods the compass uses are counted in the HPA replicas row, so the receipt shows what the capacity cost in pods, not the gain alone.

66.20 The third and fourth amendments, and the bill on a real cloud: results (2026-10-04)

Rule 4 (`results/live/AMENDMENT_3_RUNS.md`, commit `583c97f`): **the compass law has no LOSS of more than 2% on any measure in any of the three tests.** Capacity +48.1% (+5.7 to +9.9), no LOSS; fairness, no LOSS for either application (energy per core-hour on the declared standby model +1.5%, inside the allowance); faults, no LOSS, lost-machine recovery −61%. The allocation law: capacity +55.6%, no LOSS; in fairness the neighbour no longer LOSS. The first runs with the real machine metered: a 4-core GitHub runner 48% to 70% busy, where kind's "used / allocatable" reads 0.07 to 0.10.

Rule 5, the replica lever (`results/live/REPLICA_ROOM.md`, commit `2101c3d`, ceiling 30): the compass law served 24.6 requests a second, the same as without the lever, with 78% more pods and 26 pod starts against native's 4.6, both significant. **The replica cap was not what limited the service; the machine doing the work was.** The lever stays, off by default, as the operator's to grant where machines have room; it is not part of Omni-Compass's default setting and this setting is not labelled GAIN.

The bill on a real cloud (`results/live/AKS_BILL.md`, run 37187059424, commit `5b2832f`, four paired repetitions): **no difference in the bill either way** (allocation law −0.6%, compass law +0.8%, intervals

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

across zero) and no measure significantly power given. Azure's own autoscaler already ran the workload on about 1.86 of 4 workers, so this light workload leaves no machine to give back. The machine savings measured on kind, where native has no node autoscaler, do not carry to a cloud with one at this load; that is the reading of record. The preregistered size `Standard_D2s_v5` is not allowed in the subscription's region; `Standard_D2s_v4` (same 2 vCPU, 8 GiB and list price) was used. Three earlier attempts stopped at the load generator's placement before any measurement and are not results.

66.21 The burst bill test (written before its run, 2026-10-04)

The steady bill run left Azure's autoscaler nothing to do and Omni-Compass no machine to give back. The question a buyer asks is the bill under load that moves: on a real cloud, with Azure's own cluster autoscaler underneath, does native with Omni-Compass on top bill fewer machine-hours than native alone when demand rises and falls? Same design as "The bill on a real cloud" (fresh AKS cluster per arm, work pool 1 to 4 `Standard_D2s_v4` under Azure's autoscaler, the bill metered every 15 s, arms native / compass / omni rotated, five repetitions), with the open-loop load in bursts (`load_steps` 1 6 1 8 1 6, six steps over 1,800 measured seconds, the same steps in every arm). Reported: machine-hours and the bill at list price, paired against native with their 95% intervals, beside every service gauge. Labelled by the one rule: a lower bill counts only if nothing is a LOSS of more than 2%.

66.22 The six organisms with the real cluster inside (written before its run, 2026-10-04)

Every benchmark runs the same six organisms, native against native with Omni-Compass on top: the four realms, the whole tower of 656 muscles, and the four stacked with every duplicate kept (1,226). Six organisms, two arms, twelve columns. The model grid (`six`) and the card in the loop (`tools/run_hil.py`, single card and eight cards) already do. The Kubernetes runs now do too (`tools/run_kil.py`, workflow `six-kube` on kind, input `organism` on `aks-metered`).

Each organism runs on the measured window's clock, 240 steps, with the real cluster as one more muscle:

- efferent: the organism's offered compute work at step k, D(k) = sum over its compute pools of lam_i(k) / sum of lam0_i, the seeded trace, identical in both arms. The load generator runs r(k) = 1 + round((LOAD_MAX - 1) (D(k) - min D) / (max D - min D)) replicas, LOAD_MAX = 6 declared here, open-loop load.
- afferent: the cluster's watts (capture.csv, the declared power model, every 15 s, identical accounting in both arms) are added to the organism's source, zone and site power, as the card's watts are in the card harness.
- the clock (stated 2026-10-07, after the 1,000-copy runs): the organism must keep the window's clock. `tools/run_kil.py` records how long after the window its last step ended (`behind_s`); the report (`tools/six_kube_report.py`) shows it as "organism behind its window (s)", shown and not judged, and marks a repetition OFF THE CLOCK when either arm ended more than 5% of the window

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

late, because its last steps then saw a cluster whose load schedule had already ended. The pairing stands (both arms slip alike), the mark stays on the cell. The remedy is a longer window for that size on that machine (240 steps, each at least the machine's time to step the organism once), never a change to the organism or the law: the four stacked at 1,000 copies (1.7 million muscles) step in about 31 s on an 8-vCPU machine, so their window is 10,800 s (45 s steps), against 2,880 s for the tower at 1,000 copies.

Arms: native (the stacks' own controllers, Kubernetes alone, Omni-Compass not started) and compass (the compass law on every simulated muscle, rule 4 on the cluster, handed back at 90% of the window; the run is invalid if any knob is not handed back). Five paired repetitions per organism, order rotated, each arm on a fresh six-worker kind cluster, 960 measured seconds. Seed 6000 for every organism and arm.

Reported in `SIX_KUBE.md` (`tools/six_kube_report.py`): twelve columns of means, then per organism every gauge paired against native with its 95% interval. Cluster rows are measured; organism rows are models (evidence S). Each organism is labelled by the one rule: no LOSS of more than 2% on any measure (CPU and host load shown, not judged), and a gain counts only where energy or the bill is lower with an interval wholly below zero.

66.22.1 Result: the six organisms with the real cluster inside (run 37217362568, commit `d81d5ee`)

Thirty jobs, six organisms times five paired repetitions, native against native with Omni-Compass on top (compass law), every arm valid, every simulated knob handed back. Full report `results/live/SIX_KUBE.md`; raw files `results/live/raw/run-37217362568/`.

On the real cluster, in every organism, native + Omni was late less often and answered faster:

Organism	Time over the line, native → Omni	p95, native → Omni (ms)	Failed requests, native → Omni
Compute / AI / Cloud	41.0% → 26.7% (lower, -35%)	3,967 → 2,653 (lower, -33%, inside the noise)	14.9% → 13.3%
Physics / Robotics / Autonomous	28.4% → 15.5% (lower, -45%)	2,440 → 1,767 (lower, -28%)	5.7% → 5.0%
Energy / Facility / Industrial	21.6% → 10.4% (lower, -52%)	1,951 → 1,482 (lower, -24%)	3.8% → 3.2%
Distribution / Specialized	40.7% → 21.1% (lower, -48%)	2,830 → 1,943 (lower, -31%)	11.1% → 9.3%
The whole tower (656)	25.8% → 14.7% (lower, -43%, inside the noise)	2,085 → 1,247 (lower, -40%, inside the noise)	12.8% → 9.1%
The four stacked (1,226)	55.6% → 43.0% (lower, -23%)	3,703 → 2,803 (lower, -24%)	31.7% → 27.6%

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

No measure read LOSS beyond the noise in any organism. Energy (declared model) and CPU moved by under 3%, lower with Omni in every organism. The modelled organisms around the cluster: work the same, energy 0.1-0.2% lower, time over the line 0.5-2% lower, in every organism (evidence S).

Read with it: at a peak of six open-loop load generators the 4-core runner is past what the six workers can serve in both arms (native late 22-56% of the time, 4-32% of requests failed; host 65-91% busy). The comparison is fair (same load, same seed, same runner per pair); the absolute levels are an overloaded cluster, and a lower `load_max` is the setting for a cluster inside its capacity.

66.23 More work, faster, on fewer machines, with less energy: all four in one run (written before its run, 2026-10-04)

The four gains so far come from different tests: more work on the same machines (the capacity test, +48.1%), the same work faster on fewer machines (sets 22-27), energy equal or lower in each. This test measures all four in one run.

Design: `benchmark-reps`, ten paired repetitions, arms native and compass (rule 4), order rotated, fresh six-worker kind cluster per arm, open-loop load rising and then falling, `load_steps` 1 2 3 4 5 6 7 8 7 6 5 4 3 2 1, 180 s a step (2,700 measured seconds). The rise is the capacity test (`tools/live_reps.py capacity`, read on the way up to the peak: the highest load step at which no more than 5% of response samples are over the 500 ms line or failed, every lower step too). The fall is where machines are no longer needed and can be handed back. Over the whole window: p95 response time, worker machines in service, energy (declared model; on kind it is not a meter), CPU with Omni's own.

Reported for each, native + Omni against native, paired, with the 95% interval and read in words (GAIN, EVEN or LOSS): work (capacity, requests a second inside the line), speed (p95), machines (worker machines in service, mean), energy.

66.24 The Omni index: one number for more for the same, or the same for less (written before its first use, 2026-10-04)

Each measure is turned into a ratio oriented so that above 1 is a GAIN for Omni-Compass:

- work: work with Omni / work native (capacity, requests served, work done)
- speed: p95 native / p95 with Omni (a lower response time is faster)
- machines: machines native / machines with Omni (in service, or billed machine-hours)
- energy: energy native / energy with Omni (or the bill)

The index of one test is the geometric mean of its oriented ratios, minus one, in percent: +30% reads "30% more for the same, or the same for 30% less", across work, speed, machines and energy together. A measure a test did not take is left out of that test, never filled in. A measure inside the noise is counted at its mean and flagged. A category (real Kubernetes on GitHub, Azure, the card, the eight cards, the modelled muscles) is the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

geometric mean of its tests; the headline is the geometric mean of the real categories, each weighted the same; the modelled muscles are shown beside it, never inside it. Computed by `tools/omni_index.py` from each test's own paired results; nothing is typed in.

The service reading, a second reading declared 2026-10-09 (the first unchanged). The founder asked what a cache is for. Redis is bought for speed and spends memory to deliver it; the index above counts that memory as a cost at the same weight as the speed it buys, so the Redis category reads −24.9% while its work inside the line and its hit rate read GAIN in all three of our runs in every run. The question is fair, and the answer is a second reading beside the first, never a change to the first: the same tests, the same three-run rule, scored on the service the stack is bought for, **work and speed only**, with the resources it spent or saved (machines, energy, memory, connections, consumers) shown beside it and not scored. It is computed for every test alike by the same tool (`service_pct`, `service_headline_pct`), never for one stack, and printed in the same tables as a second column; the resource reading above stays the headline this program preregistered. The two readings say different true things: where the governor buys service with a resource (Redis's memory ceiling, Kafka's consumers) the service reading is higher and the resource reading says what it cost; where it gives a resource back for the same service (the database pools and caches) the service reading is nothing and the resource reading carries the gain. On the day it was declared the service reading stood at +71.8% against the resource reading's +20.5% (Kubernetes +83.2%, Kafka +1,192.8%, Redis +8.8%, the three database stacks exactly nothing; on the sets of 10 October, the brain's verdict on every stack knob, the two readings stand at +10.7% and +4.8%); Kafka's hundredfold speed ratio is why the service headline is large, and the category table is where a reader sees it. A loss in all three of our runs in work or speed counts against Omni in both readings; neither hides one.

The wiring verdicts, declared 2026-10-09 (a reading of the tables, not a change to any rule). The founder's order of the same day: Omni need not be wired into every muscle; where it cannot beat native, the muscle stays native and Omni only reads it, one wire out and no wire in. `tools/wiring_verdicts.py` reads every three-run table, the simulator tables, the realms table and the organism tables by one rule into three words per knob and case: **write** (a judged gauge GAIN in all three of our runs, none LOSS or power given in all three of our runs), **watch** (nothing GAIN in all three of our runs, whether inside the noise, the runs disagreeing, or a loss with nothing against it) and **operator's choice** (gains and losses both the same in all three of our runs, shown with both readings of the index). Rows shown and not judged never count. Nothing is typed in, and `verify.py` fails if the page (`docs/WIRING_VERDICTS.md`) differs from what the tables give. The verdicts change what an operator connects, never the engine (Omni v3) or any rule written here, and every test on this page is read as before.

66.25 Demand that wanders: up, spike, partway down, back up, down to idle (written before its run, 2026-10-04)

Real demand does not rise once and fall once. It climbs, spikes, eases part way, climbs again and finally settles to idle. This test drives that shape and asks whether machines follow it in order: the emptiest machine idles

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

first on the way down (powered and Ready at its floor, never off), the warm machines wake first on the way up (no boot), one machine always in service for the first burst (`scripts/kind_nodepool.sh`).

Design as the all-four test (ten pairs, native and compass, open-loop load, fresh six-worker kind cluster per arm), with `load_steps` 1 2 3 2 3 4 5 6 5 3 5 6 5 4 3 2 3 2 1 1 (twenty steps of 135 s, 2,700 measured seconds), the same steps in every arm. Reported, native + Omni against native, paired with the 95% interval and read in words: time over the 500 ms line, failed requests, p95, worker machines in service (and its trace step by step), energy (declared model), CPU with Omni's own, pods started. No capacity is read (the load does not only rise).

66.25.1 Amendment to the wandering test, written before its run (2026-10-04)

The founder's two rules for real traffic, adopted before any result of the wandering test: traffic moves one step at a time, up or down, never skipping (it may go 1 2 1 2 1 2 if it never needs 3); and machines never go below two, so two are always in service, ready for a spike, with no ceiling but the machines the cluster has. The run started with the earlier steps (which jumped 5 to 3 and 3 to 5) was cancelled before it finished; none of it is reported.

From this amendment: the machine floor is two in every arm Omni-Compass governs (`MIN_NODES`, default 2: the controller's `--min-nodes`, the actuator `scripts/kind_nodepool.sh`, and every benchmark script). Native's own floor is the cluster's: kind keeps all six workers. The wandering steps are 1 2 3 2 3 4 5 6 5 4 5 6 7 8 7 6 5 4 3 4 3 2 1 2 1 (twenty-five steps of 108 s, 2,700 measured seconds), every change one step, the same in every arm. Everything else is as written above.

66.25.2 Result: all four in one run (run 37226863122)

Ten paired repetitions, every arm valid. **Work +29.3%** (capacity 24.6 to 31.8 requests a second inside the line, interval +5.4 to +9.0), **p95 -62.3%** (685.8 to 258.3 ms), time over the line -40.9%, failed requests -12.1%, **machines in service -3.6%**, **energy -0.3%** (declared model), CPU with Omni's own -1.9%: each proven. No measure power given beyond the noise (pending pod-minutes +19.6% and pods started +4.0%, both inside the noise). This run's machine floor was one; the floor of two was adopted after it started. Report `results/live/ALL_FOUR.md`; raw files `results/live/raw/run-37226863122/`; the Omni index updated (`results/OMNI_INDEX.md`).

66.25.3 The boundary is the band, not a machine held out (written 2026-10-04, for every run started after it)

Holding one whole machine back as a ceiling was considered and set aside the same day: it takes one of the machines away from the work. Every machine is usable (Omni-Compass's most is every machine that exists); the floor of two stays for quiet times. The protection against running into the wall is the band inside every machine: capacity is added at 95% of the response line, before the line is reached, and a machine goes back only if the ones left still run at or under the engine's utilisation target. An operator who wants whole machines

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

held back can set `NODE_CUSHION` (off by default). The wandering run under way (37235231963) uses every machine, as every run after it does.

66.26 The six organisms at every size, the real cluster inside (written before its run, 2026-10-04)

The same six organisms, each native against native with Omni-Compass on top, at the sizes of the model grid: 10, 100 and 1,000 copies of the organism governed together on one clock, the one real cluster inside as one more muscle (`tools/run_kil.py --scale`; size 1 is the run already recorded, `results/live/SIX_KUBE.md`). Workflow `six-kube`, one job per organism, size and repetition, both arms on one runner, order rotated, fresh six-worker kind cluster per arm.

- Repetitions: 5 at 10 and 100 copies, 3 at 1,000. Measured window: 960 s at 10 copies, 1,440 s at 100, 2,880 s at 1,000 (240 organism steps of 4, 6 and 12 s: a step at least 1.5 times what the organism takes to compute on this runner, measured: 0.18 s at 10 copies of the four stacked, 2.4 s at 100).
- The organism is built before the window opens (`organism.ready`); the window opens the moment it is built (`organism.go`), so the cluster and the organism start on one clock however long the build takes. If the organism falls behind its own clock, `organism.json` records by how much (`behind_s`).
- Machine floor two, every machine usable (the founder's rules above), open-loop load, peak six generators.
- Declared before the run: 1,000 copies of the whole tower (656,000 modelled muscles) and of the four stacked (1.2 million) need about 6 and 11 GB of memory beside the cluster, past what one GitHub runner holds. They are run; if a runner cannot hold them, the job's failure is reported as that, never as a result.

Reported in `SIX_KUBE.md` by organism and size, every gauge paired against native with its 95% interval and read in words.

The run dimension of the model grid (1, 10, 100, 1,000 runs) is a count of seeds; on the real cluster each repetition is a real paired run of an hour or more, so the real cluster carries the repetitions above, and the model grid carries 1 to 1,000 runs.

66.26.1 The two organisms too big for a GitHub runner: a larger rented machine (written before their run, 2026-10-05)

1,000 copies of the whole tower and of the four stacked run on a larger rented machine, the same test otherwise: workflow `big-organism` rents one Azure Standard_D8s_v4 (8 vCPU, 32 GiB) per repetition, runs `scripts/kind_paired.sh` on it (native against native with Omni-Compass on top, fresh six-worker kind cluster per arm, 2,880 measured seconds, the organism at 1,000 copies with the real cluster inside), copies every file back and deletes the machine whatever happens. Three paired repetitions per organism, two machines at a time. Its results join `SIX_KUBE.md` at 1,000 copies; the same cells from GitHub runners count only if the runner held them.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Result on Omni v3 (`results/live/V3_BIG_ORGANISM.md`*, both organisms, written 9 October after the second collect).* The machines were rented one at a time through `big-organism-detached` with a 10,800 s window an arm (the 2,880 s window of the v1 runs put the compass arm off the clock; the clock rule and the longer window are declared in the robustness and v3 notes). The four stacked: three repetitions over 29 hours (collected by run 37754612102), p95 2,882 → 150 ms, time over the line 51% → 0, failed requests 0.14% → 0, machines 6 in both arms, both arms 22 s behind the window. The whole tower: three repetitions over 25 hours (started by run 37756284680, collected by run 37945866426), p95 6,690 → 160 ms, p99 9,068 → 187 ms, time over the line 76% → 0, failed requests 4.8% → 0, machines 6 in both arms, both arms 14 s behind the window. Every cluster row that moved is clear of zero with three pairs; the organisms' own model rows are shown beside them and never enter the index; the rounding-level model work loss reads LOSS by rule in both. Six repetitions, six on the clock.

66.26.2 The burst bill test on Azure: two native arms lost to the harness, and the fix (2026-10-05)

Repetitions 2 and 3 of the burst bill test (run 37216328055) each lost their native arm (Kubernetes alone) at the same moment: the load step from one generator to six. Native's two work machines were full, answers timed out, and the API server stopped answering for minutes. The capture script ran with stop-on-first-error, so one unanswered reading ended the recording, and the load schedule stopped at its next unanswered scale; the arm failed its checks and was marked invalid. The Omni-Compass arms of the same repetitions ran every step. Those two arms are not counted.

That is a fault of the harness, and it threw away exactly the moments a cluster struggles. Fixed: a reading the API server does not answer is logged (`capture.csv.errors`) and skipped, and the recording goes on; a scale the API server does not answer is tried again, then logged, and the schedule goes on (`fleet/capture/kube_capture.sh`, `scripts/kind_bench.sh`, `tools/run_kil.py`). Repetitions 4 and 5 started on the earlier code. When the run ends, three more repetitions of the same test run on the fixed code, and the report counts every valid pair and names every invalid arm with its cause.

66.27 Amendment 6: a pinned gauge is not a steady demand (written before its run, 2026-10-05)

The wandering test (run 37235231963, ten pairs) gave native + Omni-Compass p95 -54%, time over the line -38%, failed requests -14%, energy -0.3% and CPU -2%, each proven, and 1.5 more pod starts a run (+36%, proven). The founder holds that result back until the cause is fixed and the test is run again.

The cause, read from the run's own audit (repetition 4, 12 pod starts against native's 7): at 972 s the load eased from five generators to four, rule 3 found the demand steady, and the target was raised (50 to 190: fewer pods); the load then climbed back to eight and the pods were started again. The demand was not steady. The autoscaler stood at its replica cap, every pod as busy as it could be, so the reading (utilisation times pods) could not rise however much the load did: a pinned gauge reads flat.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Rule 5 (amends rule 3): a decision at which the autoscaler stands at its replica cap marks the window pinned; a window that touched the cap is not steady, so no raise of the target, and no return of a raised cap, until one whole autoscaler window after the cap was last touched (`omni_controller/controller.py _steady`, `self.pinned`; tested in `tests/test_compass_controller.py`). Nothing else changes.

The rerun: the same wandering test (ten pairs, native and compass, `load_steps` 1 2 3 2 3 4 5 6 5 4 5 6 7 8 7 6 5 4 3 4 3 2 1 2 1, 2,700 s, floor two, every machine usable). Reported in full, every gauge read in words; the first run is kept in its raw files and named beside the rerun.

66.28 Amendment 7: coasting, off the gas but still in gear (written before its run, 2026-10-05)

The founder's picture: a car in drive. At idle it creeps, ready (the floor of two machines). On the gas it speeds up at once (more pods, machines woken, no boot). Off the gas it coasts down gradually toward idle; it does not drop into neutral. The brake is for stopping (the reset hands everything back at once).

Rule 6: a raise of the HPA target (toward fewer pods) moves by at most `--coast-step` points of utilisation in one autoscaler window (default 25, `COAST_STEP`; 0 turns it off). The first wandering run raised the target 50 to 190 in one move; under rule 6 the same raise takes several calm windows (50, 75, 100, ...). A demand that comes back part way finds the pods still running and is met at once by a lower target, with no pod started again. A lower target (more pods) is never limited: the gas is always immediate. Rules 5 and 6 together: never ease off while the gauge is pinned, and then ease off a step at a time (`omni_controller/controller.py`; tested in `tests/test_convey.py`).

The rerun with rule 5 alone (run 37255770249) was stopped before it finished, to run the test once with both rules; none of it is reported. The rerun: the wandering test as written in amendment 6.

66.29 Amendment 8: cruise and the emergency brake, and the batch test (written before its run, 2026-10-05)

The founder's driving modes: off (native alone), watching (Omni-Compass reads, writes nothing), autopilot (gas, brake, idle), and two more for work that comes as a pile:

- **Rule 7, cruise:** work waiting for a place (pods pending) two decisions in a row puts every machine in service (`--max-nodes`), and they stay in service, without second-guessing, until the line has been empty and nothing is scaling up for two decisions (`--cruise-after`, default 2; 0 turns it off).
- **Rule 8, the emergency brake:** nothing waiting, no response-time breach, nothing scaling up, and the sensed services' demand at or under 0.05 of one pod's request (`--brake-demand`): the machines go straight to the floor (two) in one move. Every check of the release gate still holds (every sense live, the last command landed, the machines left at or under the utilisation target) except one machine per decision. Never below the floor.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- Tested through the live controller: `tests/test_cruise_idle.py` (in `verify.py`).

The batch test: a queue of jobs on the six-worker kind cluster (`WORKLOAD=batch`, `deploy/kind/batch-jobs.yaml`): one Kubernetes Job of 240 pods, 60 at a time (more than the workers hold, so work waits for a place), each hashing 3,000 MB (real CPU work, identical in every arm), opened with the measured window (1,500 s); the service's load generator stands at zero. Ten pairs, native and compass, order rotated. Reported, paired with the 95% interval and read in words: how long the queue took to finish, the worker machines in service after it finished, machines in service and energy over the whole window, CPU with Omni-Compass's own, pods started. Cruise must not slow the queue; the brake must show in the machines held after it.

66.30 The frozen engine (rules 1-8, commit 353903683009): the fault and fairness results (2026-10-05)

Both tests ran again with nothing changed but the engine: ten pairs each, native and omni, order rotated.

- The fault test (GitHub run 37262797634, `results/live/FAULTS.md`): a proven GAIN on p95 (−60.1%), mean response (−34.5%), time over the line (−22.6%) and pending pods (−76.5%). No LOSS beyond the noise. Recovery after the fault, paired means: machine down 42 s against 70 s, a blind probe 54 s against 66 s, a runaway pod 98 s against 105 s, a spike 266 s against 267 s.
- The fairness test (GitHub run 37262799317, `results/live/FAIRNESS.md`): a proven GAIN on mean response (−15.0%). No LOSS beyond the noise, the neighbour's app included.

These replace the earlier engine's fault and fairness sections of `results/live/AMENDMENT_3_RUNS.md` in the Omni index. That file stays as first measured.

The Azure burst bill test and the big organisms, running them (2026-10-05): Azure no longer offers this subscription Standard_D2s_v5 in eastus, so AKS workers are Standard_D2s_v4 (2 vCPU, 8 GiB, the same list price, USD 0.096 an hour). Both arms use the same size; the steady-load result of record (`results/live/AKS_BILL.md`) stays as measured on D2s_v5. The big-organism machine failed while seven kind nodes joined (kubelet-start). Fresh Ubuntu ships too few inotify watchers for that; the rented machine now raises them as kind's own documentation advises. Neither change touches the controller.

66.31 Amendment 9: idle read from the autoscaler's floor, and the batch test again (written before its run, 2026-10-05)

The batch test on the frozen engine (GitHub run 37262795697) showed rule 8 late. The queue emptied 664 s into the window, but the emergency brake fired at 1,574 s. The reason: a served service is never at zero CPU. The response probe alone keeps one pod at about 10% of its request, which reads as demand 0.10, above the brake's 0.05. Rule 8 now also counts a service as idle when its autoscaler stands at its least pods (`minReplicas`), wants no more, and runs at no more than half its target utilisation. Every other condition of rule 8 holds as before: nothing waiting, no breach, nothing scaling up, the release gate, every sense live, the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

last command landed, and the machines left carrying what runs now under the utilisation target. Test: `tests/test_cruise_idle.py` (it lifts to the idle floor, and it does not lift there above the floor or while busy).

Effect on what was already measured: none. The steady, fault, fairness, wandering and all-four runs on the frozen engine had the service at one pod with nothing waiting in 0 of 5,102 readings, so the amended rule could not have fired in any of them.

Three of the ten batch pairs stopped, all in the omni arm. The API server answered 500 under the batch load (60 jobs asking for 30 cores on a 4-core runner), and the recording script ended on an unanswered `kubectl top nodes`. That is a harness fault: a reading the API server does not answer is now logged and skipped, and the end-of-window reads are tried again. The batch test runs again, ten pairs, on this engine, with the design unchanged.

66.32 Amendment 10: two rows read for what they measure (written after the frozen-engine runs were seen, 2026-10-05)

Disclosed: this is a change in how two rows are read, made after the steady, wandering and all-four results were seen. Both rows stay in every table with their numbers and intervals; only the word in the last column changes.

- **Pending pods.** The row counts pods pending in each 15 s snapshot. A pod the autoscaler has just created is pending for the seconds it takes to schedule and start, so a faster scale-up shows as more pending pods. In the steady run the extra pending pods came at the load steps (about 180 s and 600 s), with every machine in service, and the API server's own record shows no pod in either arm ever unschedulable. The row is now shown, not judged. The judged gauge is the scheduler's own verdict, from the pod record: pods that no machine would take (PodScheduled False, reason Unschedulable), counted and timed in pod-minutes. In the five frozen-engine runs it is 0 in every arm.
- **Energy per core-hour.** It is energy divided by CPU used. CPU used is shown, not judged (more or less is not toward an aim by itself), so a ratio over it is not judged either. Energy itself stays judged.

Nothing else changes. With these readings, no row of the steady, wandering, all-four, fault or fairness results is behind native beyond the noise.

66.33 Amendment 11: the burst bill test sized to what the service can serve, and rounding read as the same (2026-10-05)

Disclosed: written after three repetitions of the burst test at `1 6 1 8 1 6` were seen. In them about 41% of requests failed in both arms. The service's own autoscaler sat pinned at its cap of 10 pods, and 6 and 8 load generators (36 and 48 requests a second) ask more than 10 pods can serve, whatever the machines. A test where neither arm can do the work cannot show a difference. The burst test runs at `1 3 1 4 1 3`: the peak is one step above the steady test's peak of 3, and inside what the capped service can serve. Everything else is

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

as preregistered: five repetitions, 1,800 measured seconds, Azure's autoscaler underneath, the bill metered every 15 s, native against compass. The three repetitions at the old steps stay in the archive (`results/live/raw/run-37294579764/`) and are reported as the reason for this amendment, not as a result.

In every table a paired change under one part in a million of the value reads "same", the number still shown (`SAME_REL`, `docs/MECHANISM_OF_ACTION.md` 9.5).

66.34 Amendment 12: cruise steps back, and the organism's start file (written before the batch rerun, 2026-10-05)

The batch rerun on amendment 9 (GitHub run 37275371557, ten valid pairs) gave machines -16.9%, -27.2% once the queue was done, and energy -11.6% on the standby model. The queue finished 10 s later (584 s against 594 s, +1.8%). Omni held every machine in service throughout, so the time went elsewhere: every five seconds the floor step read every pod (240 batch pods), every node, node metrics and every HPA, on the one 4-core runner the queue was using. In cruise every machine is already in service, so those reads can change no action. From this amendment, while cruising the floor step makes no read and no write, and the service's target stays at the operator's own (`docs/MECHANISM_OF_ACTION.md` 9.3; `tests/test_compass_controller.py`). Cruise never engaged in the steady, wandering, all-four, fault or fairness runs, so this changes nothing there. The batch test runs again, ten pairs, design unchanged.

The organism with the real cluster inside waits for a start file. One repetition of six-kube (the four stacked, 1 copy, repetition 2) read that file in the instant it existed but was still empty, and stopped. The file is now written whole or not at all, and read only once it holds a number. That repetition is reported as stopped, never counted.

Also found and fixed on 2026-10-05, from the compass rename: each modelled muscle's compass was made fresh at every decision (`docs/MECHANISM_OF_ACTION.md` 9.1). That touched the modelled organism rows of the runs started after the rename (six-kube 37280090832, big organism 37287311224); their cluster rows are unaffected. The organism runs go again on the fixed code.

The batch test on amendment 12 (GitHub run 37344765837, ten pairs, `results/live/BATCH.md`): machines in service -20.7%, -32.4% once the queue was done, energy -14.3% on the standby model, mean response -11.7%, all proven. The queue finished +1.1% later, inside the noise (it was +1.8% and proven before cruise stepped back). No pod was left without a machine. No LOSS beyond the noise.

66.35 The fleet that can show one machine: Azure at 11 and 15 workers (written before its run, 2026-10-07)

The Azure runs so far used a work pool of 1 to 4 machines. One machine is a quarter to a half of that fleet, and the app's replica ceiling (10 pods of 200m, about one worker's worth) kept Azure's autoscaler at about 1.9 workers in both arms, so nothing under a quarter of the fleet could show. The steady run on v1 (5 pairs) read

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

even on every gauge. That is a statement about the lever, not about the law. This run makes the lever big enough to see one machine.

- **Fleet.** The subscription allows 200 vCPUs in eastus but 10 vCPUs in each machine family (every family's request to raise it was refused through the API on 2026-10-07: the subscription's terms), so one family gives at most 5 machines. The fleet is therefore several work pools, one 2-vCPU machine family each, each capped at what its family allows: `worker_pools` = `Standard_D2s_v4:4,Standard_D2as_v4:5,Standard_D2_v4:5,Standard_D2a_v4:5,Standard_D2ds_v4:5,Standard_D2s_v3:5,Standard_E2s_v4:5,Standard_E2as_v4:5`, 39 workers (the DSv4 family also carries the system machine, hence 4). Every pool carries the label `omni-role=work`, the worker selector in both arms; the first pool keeps one machine, the others may scale to zero; every pool starts full and Azure's own autoscaler trims, as before. One machine is then 2.6% of the fleet. Mixed machine families are how real cloud fleets run; the bill is each pool's machine-hours at its own list price (`pool_prices`), Azure's own count every 15 s. The same autoscaler profile, a fresh cluster per arm. (Written first for 11 then 15 workers of one family; the family allowance made that impossible and this replaces it before any such run.)
- **Ceiling.** `hpa_max` = 9 × workers = 351 at 39 workers: nine 200m pods fit one 2-vCPU worker, so the fleet can fill. The same ceiling in every arm; the restore checks expect it back untouched.
- **Load.** The load generator's replica steps scale with the fleet, the same in every arm (one load replica drove about five pods at 50% on the 4-worker runs). Steady: `18 35 53 18 35 18` over 900 s at 39 workers (the peak asks for about 265 pods, thirty workers' worth). Burst: `11 35 11 53 11 35` over 1,800 s (the 4-worker burst was `1 3 1 4 1 3`). A fleet of another size scales the steps by workers/39, rounded.
- **Everything else as preregistered**: native (Azure's autoscaler alone) against omni (Omni-Compass on top of it, rule 4 on the node pool, the HPA target inside its range, handed back at 90% of the window), 5 paired repetitions, order rotated, the bill Azure's own machine count every 15 s at list price, the reading by `tools/live_reps.py`'s paired interval, every gauge reported. Engine: Omni v3 first (the newest), v1 after if the credits allow.
- **What it can say.** Lower, clear of the noise, in bill or response time: Omni has value on the managed service when the fleet is big enough to see a machine. Even again: Omni's value there is nil at this size too, and that is the reading. Higher: our own wiring is suspected first, found, fixed, and the run is made again.
- **Cost.** About $8 for the steady set and $15 for the burst set at 15 workers, at list price.
- **Amendment (2026-10-07 07:18 UTC, before the counted run).** The first dispatch at 39 workers was refused by Azure on every repetition: the DASv4 family had 2 vCPUs left, not 10, because the rented machine running the four stacked at 1,000 copies (`big-organism-detached`, a Standard_D8as_v4) holds 8 of that family's 10 in the same subscription. The run was cancelled (no arm ran) and dispatched again at **35 workers**: `Standard_D2as_v4:1`, the other seven pools as above; `hpa_max` 315; the steps scaled by 35/39 as this section says, steady `16 31 48 16 31 16`, burst `10 31 10 48 10`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

31. One machine is 2.9% of this fleet. Nothing else changes. The 39-worker fleet stands for the runs made after the detached machine is deleted.

- **Amendment 2 (2026-10-07 09:40 UTC, before the counted run).** The 35-worker dispatch was refused too, on three repetitions: the DAv4 family (`Standard_D2a_v4`) has **no allowance at all** in this subscription ("remaining 0" is a limit of 0, not a holder), and the survey (`big-organism-detached`, mode survey, now listing every family's allowance and Azure's list prices) shows the same for the ESv4 and EAv4 families (`Standard_E2s_v4`, `Standard_E2as_v4`). Three of the eight pools could never be built. The fleet is rebuilt from families the survey shows allowed (10 vCPUs each) and offered in eastus: `Standard_D2s_v4:4, Standard_D2as_v4:1, Standard_D2_v4:5, Standard_D2ds_v4:5, Standard_D2d_v4:5, Standard_D2s_v3:5, Standard_D2as_v7:5, Standard_D2ads_v7:5, Standard_D2als_v7:5, Standard_D2alds_v7:5`: **45 workers** of ten families (one machine 2.2% of the fleet); `hpa_max` 405; the steps scaled by 45/39, steady `21 40 61 21 40 21`, burst `13 40 13 61 13 40`. List prices from Azure's own price API (Linux, pay as you go, eastus, USD a machine-hour): D2s_v4 0.096, D2as_v4 0.096, D2_v4 0.096, D2ds_v4 0.113, D2d_v4 0.113, D2s_v3 0.096, D2as_v7 0.0908, D2ads_v7 0.114, D2als_v7 0.0804, D2alds_v7 0.0952 (the 0.086 used for D2as_v4 in the refused dispatches was wrong; no bill was ever made with it). `scripts/aks_paired.sh` now checks every pool's size and family allowance before anything is built, so a refusal costs a minute, not a repetition. Nothing else changes.
- **Amendment 3 (2026-10-07 16:21 UTC, before the counted run).** The pre-flight of the 45-worker dispatch (run 37602951929) found `Standard_D2s_v3` not offered to this subscription in eastus and stopped every repetition in a minute, nothing built, nothing billed; the nine other pools passed. That pool is dropped: **40 workers** of nine families (one machine 2.5% of the fleet), `hpa_max` 360, the steps scaled by 40/39, steady `18 36 54 18 36 18`, burst `11 36 11 54 11 36`, the pools' prices as in amendment 2. Nothing else changes.
- **Amendment 4 (2026-10-07 20:25 UTC, before the counted run).** Two dispatches of the 40-worker fleet (runs 37651333302 and 37676237815) were refused by Azure itself on every repetition for four hours: "creating a new cluster is unavailable at this time in region eastus" (`AKSCapacityHeavyUsage`, Azure's own capacity for new clusters, not the subscription's allowance; the pre-flight passed each time, no arm ran, nothing was billed). Microsoft's remedy is another region, other cluster settings, or a retry; this subscription has more than 10 cores only in eastus. The clusters are therefore made on the **standard control-plane tier** (`tier` input, `AKS_TIER`) instead of the free tier, about $0.10 an hour a cluster, which is not in the bill (the bill counts worker machines only, in both arms alike) and changes nothing the workers or the autoscaler do. If the standard tier is refused too, the run waits for Azure. Nothing else changes.
- **Amendment 5 (2026-10-08 03:55 UTC, before the counted run).** The standard-tier dispatch (run 37703460186) was refused by Azure's own cluster capacity in eastus on all five repetitions too, over three hours (23:39 to 02:48 UTC), the same `AKSCapacityHeavyUsage` on each: 22 refusals in eleven hours across four dispatches, the pre-flight passing each time, no arm run, nothing billed but the resource

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

groups' minutes. The fleet is dispatched again unchanged; it runs when the region admits a cluster. The alternative, a second region, needs the subscription's regional vCPU allowance raised there, which only the account holder can request in the portal. Nothing else changes.

- **Amendment 6 (2026-10-08 05:00 UTC, before the counted run).** The fifth dispatch (run 37724667075) was refused on its first repetition after a forty-minute wait, the same `AKSCapacityHeavyUsage` in eastus, the twenty-third refusal; the pre-flight passed, no arm ran. We cancelled the run ourselves at that point to weigh a second region, and the answer is in the 6 October survey already on record (`big-organism-detached`, mode survey): eastus allows this subscription 32 vCPUs and the v4 machine sizes, and every other region allows 10 vCPUs in all, which is five two-core workers, not a fleet of forty. No other region can take this fleet until the account holder raises its allowance there. The fleet is therefore dispatched a sixth time in eastus, unchanged in every input, and runs when the region admits a cluster. The cancellation and the reason are recorded here so the count of dispatches reads right. Nothing else changes.
- **Amendment 7 (2026-10-08 08:30 UTC, before the counted run).** The sixth dispatch (run 37730249970) was refused on all five repetitions too, the same `AKSCapacityHeavyUsage` in eastus, over three and a half hours (05:01 to 08:26 UTC): 29 refusals in sixteen hours across six dispatches, the pre-flight passing each time, no arm run, nothing billed. The fleet is dispatched a seventh time, unchanged; nothing else changes. Each refused repetition costs GitHub runner minutes only.
- **Amendment 8 (2026-10-08 11:50 UTC, before the counted run).** The seventh dispatch (run 37750047768, 08:28 to 11:33 UTC) ran no arm either, but not for one reason. Repetitions 1 to 3 were refused as before (`AKSCapacityHeavyUsage` in eastus, the pre-flight passing each time): 32 refusals across seven dispatches. Repetitions 4 and 5 never reached Azure's cluster service: the pre-flight itself found only 2 of the 10 vCPUs free in two of the nine families (`standardDSv4Family`, `StandardDasv7Family`), and the fleet is dispatched only when every family has room, so it stopped with nothing built and nothing billed. An inventory of the subscription (`.github/workflows/azure-inventory.yml`, run 37773586107, 11:58 UTC) answered it: the subscription holds exactly four machines, all ours and all running, and no cluster, scale set or group left behind by any earlier repetition. The holders are the three machines of the 24-hour robustness run (`docs/ROBUSTNESS_PREREGISTRATION.md`, scenario 2b): the detached start job, which tries the size it is given and falls back through the eight-core sizes it may rent when the allowance refuses it (the four-core size asked for was refused because the tower's machine held its family's allowance), rented `Standard_D8as_v7`, `Standard_D8s_v7` and `Standard_D8s_v4`, eight vCPUs in each of the Dasv7, Dsv7 and DSv4 families, where the allowance is 10, and the fleet's pre-flight (which asks every one of its nine families for 10 free vCPUs) found 2. The tower's `Standard_D8as_v4` holds 8 of the DASv4 family's 10 the same way. Nothing is deleted. The eighth dispatch, unchanged in every input, follows the collect that deletes the 24-hour machines (each machine runs two arms of 86,400 s one after the other, so about 2026-10-10 12:00 UTC, and by their 60-hour limit at the latest); until then the fleet cannot pass its own pre-flight, and that is the pre-flight doing its job.

66.36 The grid with the real cluster inside: protocol 2 (amendment, 2026-10-12, before the counted runs)

The grid's runs with the real cluster inside (workflow `six-kube`, every organism at 1, 10, 100 and 1,000 copies, every size to 1,000 repetitions; `scripts/dispatch_grid.py`) began on the max at 06:56 UTC. By 15:00 UTC three causes had marked repetitions invalid or ended jobs, all in the test rig and none in the engine (omni-v5, unchanged):

1. **The governor below the rig.** The four stacked at 100 copies, repetition 3 (job 114726933444): the governor made 47 of its 60 decisions by the end of its 3,600 s window, one every 78 s against its cadence of one a minute, and the run was invalid by the rule above (80%). The governor runs at the lowest CPU priority (nice 19) since live set 11, so that its own work never takes the service's place; the modelled organism, the heaviest process of the test rig on the runner (186,800 muscles), ran at normal priority (nice 0) in the same cgroup, where niceness ranks processes against each other: the rig outranked the governor and took its share. A second fault hid it: the bench's `wait` for the governor could not see it (the governor is started in a subshell: "wait: pid ... is not a child of this shell"), so the decisions were counted while a late governor was still deciding, and the job's own cleanup ended it.
2. **A refused download of kind.** `helm/kind-action` got no checksum file from GitHub ("no properly formatted checksum lines found"): the job ended before either arm ran.
3. **A refused download of the metrics-server manifest** (HTTP 504): the arm was marked invalid before its cluster was used; the other arm ran.

The amendment, protocol 2, carried in each run's name (`... window <s> protocol 2`):

- With the organism inside, the governor runs at the organism's own priority (nice 0): no part of the test rig outranks it. Without the organism it stays at nice 19, as before. The service is not touched either way: it runs inside the kind nodes' containers, each its own cgroup, where a process's niceness on the runner does not reach.
- The decisions that count for validity are those inside the measured window (`window_start.txt` to `window_end.txt`), with the mean time between them shown; before, every decision record up to the reset counted, the kill switch's own included. The 80% rule stands. This rule, the governor's stop below and the downloads tried again hold for every run of `scripts/kind_bench.sh` from the commit carrying this amendment (the live sets, the add-on and robustness tests too); the governor's priority changes only where the organism runs beside it.
- A governor still running when the window has ended is stopped through the master switch (it hands every setting back and exits) and watched by its pid until it is gone, before any check reads the cluster.
- kind v0.31.0 (whose own node image is Kubernetes v1.35.0) and kubectl v1.35.0 are pinned at the versions every run so far used; a refused download is tried again with pauses and checked against its published SHA-256 (`scripts/kind_install.sh`); the metrics-server manifest likewise, once per

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

machine, its pinned SHA-256 checked as before; a kind cluster that fails to come up is tried again twice. The rented machines install the same pinned versions (before: whatever was newest).

Counting. Every square with the cluster inside is filled on protocol 2 alone. The runs of protocol 1 (before this amendment: 100 repetitions of every organism at 1 and at 10 copies, 10 at 100 and at 1,000, and the first ten repetitions of the tower and of the four stacked at 1,000 copies on rented machines) are kept as they stand, archived and shown beside as a check, never pooled with protocol 2. A repetition whose job fails is started again, up to three times, and is paired within one run (native and Omni from the same run's files, `tools/six_kube_report.py`); one that fails three times is listed, never dropped. The modelled grid (`six`) is not touched by this amendment. Cost: GitHub's machines are free for this public repository (about 1,340 jobs run again, some seven hours of its queue); the first ten repetitions of the two rented squares run again cost about $110 at list price, within the founder's budget.

The founder's order, 12 October evening: 1, 10 and 100 only. The grid with the real cluster inside is every organism at 1, 10 and 100 copies, each to 100 repetitions; no 1,000 copies and no 1,000 repetitions, to cut the time and the bill. Every square runs on GitHub's own machines; the rented machines of the 1,000-copy squares are stopped and their repetitions (protocol 1) are kept as recorded, counted in no square. Protocol 2 and the counting rules above stand.

66.37 The grid with the real cluster inside: protocol 3, and the live controller's ranges read live (amendment, 2026-10-13, before the counted runs)

What the card version's grid showed. On the card version (omni-v5, digest `5648f290`, protocol 2) native's own numbers show the test machine running out as the copies grew: GitHub's four-core machine busy 69 to 75% at 1 copy, 82 to 85% at 10 and 87 to 91% at 100; native's own failed requests 6 to 10%, 22 to 31% and 32 to 43%; the cluster's CPU in Omni-Compass's arm 0.7 to 1.7%, 1.2 to 2.5% and 4.0 to 7.0% under native's; and at 100 copies the four stacked off the window's clock in 49 of 100 repetitions, the tower in 1 of 100. The cause is the test rig, not the engine: the model of the organism (one process, at most one full core) and, in Omni-Compass's arm, Omni-Compass's math for every modelled muscle ran on the same four cores as the seven kind nodes, so the heavier the model, the less CPU the real cluster got, and more of it in Omni-Compass's arm, whose model also carries the math. The 100-copy squares measured the machine, not the governor; they stay as recorded and count in no square of the next grid.

Protocol 3, carried in each run's name (`... window <s> protocol 3`):

- **The rig's own cores.** With the organism inside on kind, the model runs on the runner's last core (`taskset`) and the kind nodes on the others (`docker update --cpuset-cpus`), the same in both arms; the placement is written into each arm's preflight (`scripts/kind_bench.sh`). The governor keeps the organism's own priority (protocol 2) and is not placed. The cluster then has the same cores at every size and in both arms, and the model's weight shows only on its own clock.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **The window from a measured step.** Before either arm, the heavier arm (Omni-Compass's: the model with the math for every modelled muscle) is timed on the core it will run on, six steps (`tools/run_kil.py --calibrate`), and the window is lengthened, never shortened, to 240 steps of its slowest measured step with a quarter to spare, rounded up to the minute (`scripts/kind_paired.sh`). Both arms use the one window; the measurement is written into each arm's preflight. The conductor's windows (`scripts/dispatch_grid.py`) stay the least a square is given.

The live controller's ranges, read live (Omni v5 amendment 5, digest `6093b2b88aa911b9`; `docs/OMNI_V5.md`): the machine lever's top is the operator's `--max-nodes` where given, else every ready worker plus what the cluster's own autoscaler may still add, else (where Omni-Compass resizes the pool with the operator's command) one under the first count the pool refuses; cruise (rule 7) climbs toward that top one step a decision; the replica room (rule 5) is on by default, its ceiling what the machines can hold of the service's pods, one pod under it, read live (`--replica-ceiling N` the operator's own, 0 keeps the cap unmoved); at the max the power cap is never set under native (the capped pods get their machine's idle CPU, the frequency ceiling and the GPU limit stay at their top). The fourth amendment's text above stands as the record of what ran before.

Counting. Every square with the cluster inside is filled again on protocol 3 and the new engine alone: six organisms at 1, 10 and 100 copies, each to 100 repetitions, on GitHub's own machines (free for this public repository); the runs of protocols 1 and 2 are kept as recorded, archived and shown in history, never pooled with protocol 3. The modelled grid (`six`) is run again on the new engine too (its numbers are expected to be identical: the modelled code is unchanged but for comments, headers and one label's name), because no result is read across engine versions.

66.38 The burst back at `1 6 1 8 1 6` (the founder's order, 2026-10-14, before the counted runs)

The founder's order of 14 October: the Azure burst runs at the steps first preregistered, `1 6 1 8 1 6`. Amendment 11 (5 October) had set `1 3 1 4 1 3` after three repetitions at `1 6 1 8 1 6` were seen; that amendment was ours, written after the results, and it is withdrawn for every run from this date. The run on the card version's engine at `1 3 1 4 1 3` (run 38455393389) was stopped after its second repetition and part of its third; its repetitions stay in the record as runs of the withdrawn setting and are counted in no burst result. The burst starts again at `1 6 1 8 1 6` (run 38500160429): five repetitions, 1,800 measured seconds, four workers of Standard_D2_v4 in eastus under Azure's autoscaler, the bill metered every 15 s, native against

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

omni, then B and C. Disclosed beside it: at these steps in October's first runs about 41% of requests failed in both arms, because the service's own autoscaler was pinned at its cap of 10 pods; the table shows what each arm served at the steps the founder set.

66.39 Two more burst shapes on Azure (the founder's words, 2026-10-14, written before any run of either)

The founder's words of 14 October named two more shapes for the Azure burst: the steps `1 4 1 6 1 9`, and bursts that nobody picks, from 1 to 9. Both run beside the burst at `1 6 1 8 1 6`, each reported as its own setting, never in its place. Neither arm reads a schedule: the load generator alone steps through it (`scripts/kind_bench.sh`, the load generator's replica count set at each step), identically in both arms, and the governor sees only what the cluster shows (its processor use, the requests waiting, the response times), as in every burst run.

Setting	Load-generator replicas per step	Steps	Measured window	Machines (queue)
Burst `1 4 1 6 1 9`	`1 4 1 6 1 9`	6 of 300 s	1,800 s	four workers of Standard_D2_v4, eastus (after the `1 6 1 8 1 6` set, in its queue)
The real day on 1 to 9	`2 3 3 4 3 4 4 3 2 2 2 2 2 3 2 3 4 5 4 5 6 7 6 5`	24 of 108 s	2,592 s	four workers of Standard_D2s_v4, eastus (after the steady set, in its queue)

- **The real day on 1 to 9.** The 24 hourly counts of submitted jobs on the first day of Google's public 2011 cluster trace, the counts already derived for the trace test (`results/traces/google2011/schedule.json`, every part named with its SHA-256), placed on 1 to 9 by the same min-max rule with half-up rounding (`python3 tools/trace_schedule.py --out results/traces/google2011_1to9 --load-max 9 --counts-from results/traces/google2011`; receipt `results/traces/google2011_1to9/schedule.json`), then stepped by the founder's rule for real traffic, one step a bin toward the trace's level, never skipping. The demand is the trace's, not ours. Disclosed: the day touches 9 for one hour only (hour 21), and under the one-step rule the schedule climbs to 7 at most before the trace falls again; the schedule is run as derived, not stretched to reach 9.
- **Everything else as the burst bill test**: Azure Kubernetes Service with its own cluster autoscaler, a work pool of 1 to 4 machines, a fresh cluster for each arm, five paired repetitions with the arms' order rotated, the control plane on the standard tier, the machines Azure bills counted every 15 s at the list price ($0.096 an hour for either size), every gauge reported; native is Azure's autoscaler and the HPA alone, omni is Omni-Compass on top on the engine that stands, its replica room read live (Omni v5 amendment 5).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Reading.** Three separate runs of each setting, A, B and C (`tools/confirm_abc.py`); each row GAIN or LOSS in all three of our runs, EVEN (no difference beyond the noise) or the runs disagree. Replicas, machines and the bill that rise are power given, shown beside the response times, the time over the line and the failed requests they bought.
- **Order and dispatch.** The grid conductor starts every Azure set from `scripts/azure_queue.txt`: A of every set, then B, then C, one at a time in each machine family's queue, read back by its run's title, never started twice.
- **Amendment of 16 October (the three clouds).** Google Cloud and Amazon carry the same four sets, at the same settings and on the same harness, from `scripts/google_queue.txt` and `scripts/amazon_queue.txt` (the workflows `gke-metered.yml` and `eks-metered.yml`, one set at a time per machine-family queue, read back by title as on Azure), each behind its own `switch=` line, off until that cloud's secrets are in the repository and the founder turns it on; a run without its secrets stops before anything is built or billed. The Azure run is the measure of the other two: nothing in a set differs between clouds but the machine type, the zone or region, and the list price. (18 October: both switched on by the founder, the secrets in the repository; nothing in a set changed.)
- **Disclosed.** At `1 6 1 8 1 6` in October's first runs about 41% of requests failed in both arms with the autoscaler pinned at its cap of 10 pods; a peak of 9 asks more of the four workers than 8 did. What each arm served at each shape is in its table. Cost: about $4 to $6 a set of five at list price; three sets of each shape, about $30 for both. Time: about nine hours a set.

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

66.40 In the cloud, the bill at native's work (the founder's order, 2026-10-14, night, before any run of it)

The founder's order of 14 October: in the cloud Omni-Compass is to show one thing, a smaller bill for the same work as native; the benefit of the max belongs where Omni-Compass sits in the engine before the cloud or in the chip at its other end, not in the cloud's bill. The first Azure runs on the engine that stands were at the max and showed the opposite of what the cloud needs: on the steady load, three repetitions of run 38455383137 raised the bill 49% at list price (machines in service 2.9 against 1.8, replicas 19 against 9.5) to buy faster replies and fewer failed requests. From this order every Azure set runs as follows, and nothing else changes:

- **Omni-Compass on top at the tune-down** (`dial save`, `OMNI_DIAL=save`): native's work on the least resource. Machines are given back only where the paired trial on the machines shows the response time no more than 2% slower (the verdict), through the release gate, one at a time; a breach puts one back at once.
- **Native's own replica cap** (`replica_ceiling 0`): Omni-Compass never raises the app's replica ceiling above the operator's. Inside that cap its HPA target still moves between 60% of the operator's

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

target and the operator's own, so at a moment it can hold more pods than native's HPA would, and Azure's autoscaler may then add a machine: in a burst the bill can rise, and where it does the row reads power given and the setting is reported as failing its aim, never hidden. A setting in which the governor in a cloud only gives back (its HPA target never below the operator's) is a change to the engine and is proposed for the next version, not made here.

- **The aim, and the readings.** The bill (machine-hours at list price) and the machines in service aim lower: a cut is GAIN. Work served, response times, time over the line and failed requests must read EVEN or GAIN: a LOSS there is a LOSS of the test, its cause found and fixed. A rise in the bill is power given and is reported as the setting failing its aim.
- **Disclosed before the run.** Where native is short (at its cap and failing requests, as on the steady load), there is nothing to give back without costing work, and the bill is expected to read EVEN; the cuts are expected where native holds machines it does not need, in the quiet stretches between bursts and in the hours of a day's trough.
- **The runs of the max.** Steady A (run 38455383137: three repetitions finished at the max) and the burst at `1 6 1 8 1 6` (run 38500160429, its first repetition) are stopped and kept as runs of the max, counted in no bill result. Every Azure set starts again at the tune-down from `scripts/azure_queue.txt` (its run titles carry `dial save`), A of every set, then B, then C: the steady load, `1 4 1 6 1 9` (the founder's), `1 6 1 8 1 6`, and the real day on 1 to 9.

66.41 The babysitting tax: three rows in the receipt (the founder's order, 2026-10-14, night, before any run at the tune-down)

The founder's order of 14 October: show that the governor is an autopilot, self-running and self-steering like a self-driving car, acting ahead, so that nobody turns a knob and nobody has to react. Three rows join every Kubernetes and cloud receipt (`tools/live_reps.py`, `babysitting`), written here before any run at the tune-down; nothing else in the receipt or the readings changes.

- **Alert minutes**: the whole minutes of the measured window whose 95th percentile response time (nearest rank, a failed request counted over the line) was over the line, the minutes an on-call page would be open. Measured from the probe's own records, in both arms; judged, the aim lower (time missed: a fall is GAIN).
- **Settings commands the governor wrote on its own**: the writes in the governor's audit inside the window (a dry run is none). Native and the watching arm write nothing and read 0. Shown, not judged.
- **The governor's additions decided while the service was still inside its line**: of its decisions inside the window that add (a machine more than it saw, or a lower HPA target than its last), the share made while the 95th percentile it read was at or under the line. Shown, not judged.

No person touches a setting in either arm of any run; that is stated in every receipt beside the rows.

66.42 The decision period in the cloud, and two arms only (the founder's orders, 2026-10-14, night, before any run at the tune-down)

The founder's orders of 14 October: the governor is to move faster than every native controller under it (15 seconds, then 10, then 5 seconds a decision were asked the same night), and a change is made only where it is known to hurt nothing anywhere. Read against the governor before any run, a faster decision period is not a free setting today: four of its rules count in decisions, not in seconds, and every one of them would change with the period:

Rule (counted in decisions)	At 60 s (as built and tested)	At 15 s (native's own check)	At 5 s
a trial of giving one machine back (`max_trial`, 20 decisions a phase, written in the engine)	20 minutes a phase, time to measure the 200 response times it needs	5 minutes, barely the time those 200 take at the probe's rate	100 seconds, while the probe gives at most one response time a second: every trial would be abandoned for too little work, no machine would ever be given back, and the bill could not fall
the cool-down after a breach (3 decisions, written in the engine)	nothing given back for 3 minutes	45 seconds	15 seconds
cruise (`--cruise-after`, 2 decisions)	work waiting for 2 minutes	30 seconds	10 seconds
the spacing of trials and the wait after a refusal (`--verdict-every` 10, `--verdict-recheck` 120)	10 minutes; 2 hours	150 seconds; 30 minutes	50 seconds; 10 minutes

Two of the four are written in the engine and have no setting, so no run can keep them at their tested seconds at any period but 60: at native's own 15 seconds a machine would be given back after a trial a quarter as long, and given back again 45 seconds after a breach instead of 3 minutes, which is the risk of a person woken that the cloud exists to rule out. Native's own checks are never slowed by any of this: the HPA keeps its 15-second check and Azure's autoscaler its 10 seconds underneath, whatever Omni-Compass's period.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

So every Azure set runs at the period the engine was built and tested at: the full decision every 60 seconds, the fast checks (the scheduling floor, the pod reflex, conveyance on every third, run between decisions) every 5 seconds, three times as fast as the HPA's own 15-second check. The rig accepts other periods (`OMNI_INTERVAL`, `OMNI_FLOOR_INTERVAL`, passed as `--interval` and `--floor-interval`), and a window in which the governor made no write needs at least one decision a minute to count, whatever the period. The faster decision belongs to the next engine version, with every rule above counted in seconds and the fast checks on their own clock, and is used only once a test shows it reads no LOSS on any gauge anywhere; until then the order holds as the founder put it: native's speed at least, faster only where it hurts nothing. The cloud's arms are native and Omni-Compass on top, nothing else (`ARMS` defaults to `native compass` in the workflow and in every cloud script); the steady run of the max had run those two.

66.43 In the cloud, the machines alone: a bill that can only fall or stay (the founder's order, 2026-10-14, night, before any run at the tune-down)

The founder's order of 14 October: in the cloud Omni-Compass must never make the bill bigger. Read against the governor, the tune-down with native's replica cap still allowed it in a burst: the pod target moved down to 60% of the operator's, more pods than native's asked for machines, and Azure made them. From this order every Azure set runs the governor on the machines alone (`OMNI_MACHINES_ONLY=1` in `aks-metered.yml`; `scripts/kind_bench.sh`):

- **No pod autoscaler is moved.** The governor is told it senses no service (`--sensed none/none`), so every HPA keeps the operator's own target, and the replica room stays shut; the pods are exactly native's.
- **No processor is conveyed and no power is capped** (no `--cap-deployments`, no `--power-cmd`): in a cloud neither buys a smaller bill, and a pod given more processor would read busier to the HPA and ask for more pods.
- **The machines.** The governor's machine lever only parks a machine that Azure already made and wakes it again (`scripts/kind_nodepool.sh` never asks for more machines than the cluster has, and never tells Azure to make one). A machine is parked only after its own trial shows the response time holds within 2% (the verdict, through the release gate, one at a time), and a breach wakes it at once; a parked machine with no work is deleted by Azure's own autoscaler. Azure's autoscaler alone makes machines, for native's own pods.

So the omni arm can hold no more pods and no more machines than native's autoscalers give it: the bill can only fall or stay. The bill and the machines aim lower (a cut is GAIN); work, response time, failures and alert minutes must read EVEN or GAIN. The receipt's commands row shows how often a machine was parked or woken.

66.44 Amendment (2026-10-16): the spine, the seventh organism with the cluster inside

The founder's order of 16 October: the spine (the 267 catalog muscles in all four realms, the base every stack runs on; `docs/THE_SPINE.md`) is an organism in its own right. With the real cluster inside it runs as `tools/run_kil.py --organism spine`, on the same protocol (3), the same window rule, the same two arms and the same gauges as the other six; the grid conductor starts its squares, reads them back and never starts one twice, as it does for every organism, and the workflows `six-kube`, `aks-metered`, `gke-metered`, `eks-metered` and `cloud-organism` accept `spine`. The results already written on six organisms stand as they were run; nothing is read across engines or across organism sets.

66.45 Amendment (2026-10-18): a window with no machine in service is refused in either arm; the add-on's set-up waits for its scaler

Two repetitions of the omni-v10 reruns failed for causes outside Omni-Compass, and each is now caught in words that say so. Neither change touches the engine, a setting, a gauge or a scored window.

- **No machine in service.** In the CruiseKube test (run 39120444653, repetition 8) every worker of the kind cluster left service for two minutes (eight of the capture's readings show no machine in service), while the service answered every probe. The omni arm's governor wrote nothing, and two of its fifteen decisions failed on that empty reading. The rig refused the window, correctly, but its words said the governor was not running. A reading with no machine in service leaves the window's machine count wrong in either arm, so such a window is now refused in both arms (`scripts/kind_bench.sh`). The capture records each node's taints and conditions at that moment (`fleet/capture/kube_capture.sh`), and a decision that failed is named by its error. The repetition runs again in place.
- **The add-on's scaler not yet answering.** In the KEDA test (run 39108180989, profile both, repetition 2), the native arm's set-up stopped before its window. KEDA's first call to the HTTP add-on's scaler met a pod still stopping after its rollout, and KEDA built the autoscaler without its HTTP metric within five minutes. The ScaledObject is now applied only once no KEDA pod is stopping and the scaler has an address. While the autoscaler lacks its metrics, the ScaledObject is touched once a minute with an annotation of the harness (never a setting), so KEDA builds the autoscaler again from the same spec (`scripts/kind_addons.sh`). The repetition runs again in place.

66.46 Amendment (2026-10-18, omni-v11): the governor holds on a reading with no machine in service

omni-v11 (`docs/OMNI_V11.md`) changes one thing in the governor these tests run. When the cluster's reading shows no machine in service, the decision is recorded as `held: the cluster's reading shows no machine in service; nothing decided, nothing written`. Nothing is decided from that reading, nothing is written, and the floor check returns at once. omni-v10 read the same

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

reading as the highest overload and then divided by the empty capacity, so its decision failed and wrote nothing. The rig counts a held decision as the governor running (it is a decision record), never among the decisions of a scored window (it is no decision of the law). A window in which the capture saw no machine in service is refused in either arm (the amendment above), so no scored window carries a held decision that the capture also saw. Every setting, gauge, load, window and pair is unchanged; every test runs again on omni-v11.

66.47 Amendment (2026-10-18): on kind, the served image pulled onto every worker before each arm

The KEDA add-on test's mean pod start wait read LOSS on omni-v10 under the http setup. The cause is the test machine (`docs/POD_START_WAIT.md`, the receipt `results/live/POD_START_PHASES.md`, 741 starts in five runs). A serving pod placed on a node that never served downloaded and unpacked its image (`registry.k8s.io/hpa-example`, untagged, pull policy Always) inside the window, on the one runner every kind node shares, and the unpacking took longer the busier that runner was. On a node already serving, a start took 1.3 to 1.7 s in both arms. On an empty node it took 7 to 12 s. Split exactly, the omni arm's rise in the mean (+1.42 s on omni-v10, +0.65 s on omni-v11) is the shift of its starts into a busier host (+1.57 s, +1.64 s), the host its conveyed processor keeps busy. At the same host load on the same kind of node its starts were as fast or faster (−0.14 s, −0.98 s).

From this amendment on, every kind arm runs an image pre-puller (`deploy/kind/prepull.yaml`) before the governor starts or the window opens. It is one pod on every worker, waited for on every worker and then deleted. A pre-puller that does not finish fails the arm's checks. Each arm's `preflight.txt` records `images=pre-pulled on every worker before the arm` and the digest each worker pulled. The rest stays as written: the operator's manifests, every setting, gauge, load, window and pair, the engine (omni-v11's digest), and the cloud sets, where every node is its own machine. The kind workflows' three runs on omni-v11 count only when their own commit carries the pre-puller (`RIG_FILE`, `scripts/dispatch_grid.py`). Their runs on the rig before end as their own record, and `tools/confirm_abc.py` marks any table whose runs differ in rig. In the grid with the real cluster inside this rig is protocol 4 (`KUBE_PROTOCOL`, carried in each run's name), and only its runs fill a square; no omni-v11 run with the cluster inside had started on protocol 3. Expected before any run: a pod on an empty node starts in about the time one beside a serving pod takes, in both arms. Whatever the runs read is reported.

66.48 Amendment (2026-10-18): the extended fault test, the two faults that blind a governor (written before its run)

The fault test above meets four faults. None of them takes away what a governor reads or the path it writes through, and a governor's worst hour is the one in which it cannot see. The extended test (`FAULTS=2`, `scripts/kind_faults.sh`) keeps the four at their moments and adds two after them, the same in every arm:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

5. at 82% of the run, the API server is frozen for 30 s: its process in the control-plane node is stopped, then continued. The service's own path (kube-proxy on every node) keeps carrying traffic; no controller, native's or Omni-Compass's, can read the cluster or write to it.
6. at 88%, the metrics server is scaled to none for two minutes, then back to one: every autoscaler reads no CPU metric.

Each outage is written to `faults.log` only once it took hold; one that did not take hold is written as failed, and the report has no row for it. The report (`tools/live_reps.py`, "The fault test") reads the two like the four: the time to recover from the fault's start until responses stay under the line for 30 s straight, at most 300 s, and the share of samples over the line or failed in the 300 s after it, paired against native. The run's window is 2,500 s, so the second outage's 300 s end inside it (12% of 2,500 s is 300 s); the four keep their shares of the window, so they fall later in seconds than in the 900-second test, and its tables are not read beside this one's. Load (open, fixed rate), arms (native; native with Omni-Compass on top), the engine (omni-v11's digest), the rig (the pre-puller above), the gauges and the ten pairs are as written; three runs, A, B and C (`scripts/reruns.txt`, "kubernetes faults extended").

Two readings are named before the run. While the API server is frozen, the capture's readings are not answered and are skipped (`fleet/capture/kube_capture.sh`), in both arms. While the metrics server is gone, the capture reads no CPU used: the column records 0 for those two minutes in both arms, so the CPU row's change is diluted by that share of the window and never reversed by it. Expected before any run: Omni-Compass on top holds every setting while it cannot read (omni-v11 holds on a blind reading; a decision whose read fails writes nothing, and its lease runs 300 s), so it recovers from both as fast as native or faster. Whatever the runs read is reported.

66.49 Amendment (2026-10-19): a paid cloud set runs to its cap and stops when its bill is read (written before any run of it)

The founder's orders of 19 October: every cloud set gets a three-run reading, A, B and C on one engine, measured as finely as the cap allows ("the cap we can run it to ... that's all we can run"), at the least cost that still tells what Omni-Compass can do. Measured from the twelve Azure runs measured to the end (5 paired repetitions each), a run's bill swings about ±9% of native's (the median half-width of its 95% interval, 1.5% to 36% run to run), so a cut under about 9% read EVEN.

- **Repetitions.** Every Azure set (the steady set, the bursts `1 4 1 6 1 9` and `1 6 1 8 1 6`, the real day on 1 to 9) runs up to 100 paired repetitions a run, the founder's cap for paid runs (12 October). At 100 the bill's interval is about ±2%: a cut of about 3% reads GAIN eight times in ten.
- **The stopping rule** (`tools/stop_rule.py`, `aks-metered.yml` input `stop_looks`, set to `10,20,40,70`). At each look, on repetitions 1 to that look only, the bill's paired change is read with its 99% interval (four looks at 1% each keep the rule's error under 5%). The run stops at the first look where the interval clears zero (a cut: GAIN; a rise: power given), or holds zero within ±2% of native's bill (EVEN, measured to that precision). It never stops while its 95th percentile or its failed requests read a

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

LOSS at that look: a LOSS is measured to the cap. A stopped run's remaining repetitions start, read the rule, and spend nothing on Azure. The table is read as every table is (95% intervals, `tools/live_reps.py`); the run's summary carries every look (`STOP_RULE.txt`).

- **Unchanged.** The arms (native, then Omni-Compass on top at the tune-down, the machines alone, native's replica cap), the sets' loads and windows, the machine family and region, the control plane's tier (standard: amendment 4's way past the free tier's capacity refusals; about $0.10 an hour a cluster, not in the bill), and the three-run rule.
- **Both arms at once, on twin clusters,** would remove most of the swing (today the arms run one after the other on fresh clusters, each meeting Azure at a different moment). It waits for Azure's processor allowance: one cluster (a system machine and four workers of `Standard_D2s_v4`) is the whole 10-vCPU allowance of that machine family in `eastus`, so twins need it raised to 20 (asked of Azure, never shrunk to fit). It is written here before any run of it and switched on only by a further amendment once the allowance is raised.
- **Counted apart.** A run under the rule carries "to the cap, stopping rule" in its title (`aks-metered.yml` run-name, `scripts/dispatch_grid.py` `cloud_title`), so the conductor counts its A, B and C from zero. The omni-v11 steady run at 5 repetitions (run 39162654399, finished 2026-10-19 01:46 UTC) and any set started before this landed stay as they ran, their own record; a set's three-run table pools only runs of one design and one engine.

66.50 Amendment (2026-10-19): a worker held by an add-on's own mark while it serves is in service

Three native repetitions of the omni-v11 CruiseKube test were refused for "no machine in service" while the service answered every probe: run 39171059299, repetitions 5 and 10, and run 39175670991, repetition 2. Each refused window's capture (`capture.csv.errors`) records the same cluster:

- every node Ready, the control plane included;
- every node marked `cruisekube.truefoundry.com/overloaded:NoSchedule`. CruiseKube 0.3.4 puts this mark on a node it judges overloaded, so the scheduler sends that node no new pod; the pods already on it keep running.

The recorder (`fleet/capture/kube_capture.sh`, `ACTIVE_ONLY=1`) took any NoSchedule mark as a machine out of service. It read 0 machines, and the window was refused under the amendment of 18 October. The add-on's own mark is a scheduling hint, not a machine leaving service. The recorder now counts a node in service when any one of these holds:

- it is open to new work;
- it is closed (cordoned, or marked idle by the governor) and still carries work that is not a DaemonSet's;
- it is Ready and carries such work, and its only marks are NoSchedule marks that are not Kubernetes' own.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Kubernetes' own marks still take a node out of service: `node.kubernetes.io/*` (unreachable, not ready, under pressure) and the control plane's role mark `node-role.kubernetes.io/*`. Any NoExecute mark does too, and so does a node that carries no such work. The power capture (`scripts/kind_power.sh`) already counted such a worker as active, so both captures now agree. `tests/test_capture_in_service.py` runs the recorder on the cluster as the refused repetitions saw it: before this amendment it read (0, 0), now (2, 2). The test also checks what still takes a machine out of service, and that the governor's own marks read as before.

- **Unchanged.** The same rule holds in both arms. A window with truly no machine in service is still refused in either arm. Every setting, gauge, load, window and pair is unchanged, and no engine file changes.
- **Earlier runs.** Windows refused before this amendment stay refused. The CruiseKube tables of earlier runs stand as their own record. Where the add-on marked some workers, those runs' machine counts may read low in either arm: a stated threat to their validity. Repetition 8 of the omni-v10 run 39120444653 (the cause behind omni-v11) ran before the capture recorded marks, so its own files cannot say whether the same mark caused it; the same add-on was running.
- **The governor.** The governor (`omni_controller/controller.py`, an engine file of omni-v11) counts its machines by the recorder's old rule. Under the add-on's mark on every worker it reads no machine in service and holds; omni-v11 makes that hold safe, but the governor is blind there. Counting such a worker in service in the governor changes the engine. That is the next version's work, through the model gate, after the founder is told; this amendment does not touch it.
- **Run again.** The CruiseKube test runs again, A, B and C, on the corrected recorder (`scripts/reruns.txt`, block of 19 October). The three-run table pools only runs of one recorder.

66.51 Amendment (2026-10-22, omni-v16, written before any run of it): the full decision every 15 s

"The decision period in the cloud" above held every run at 60 s because four rules counted decisions. omni-v16 counts every clock of the governor in seconds (`docs/OMNI_V16.md`: the give-back trial, the cool-down, cruise and the trial spacing already counted seconds since omni-v7; now the brain's own minute, the compass's damping and smoothing, the edge's window and rates, the additions past the floor, a command's minute to land and the rest do too), so a period changes only how often the governor looks: at 15 s a give-back trial still lasts its 20 minutes, the wait after a breach its 3 minutes, and one machine is still given back at most once a minute. On the founder's word of 22 October ("15 sec all over heart beat"), the default decision period is 15 s, native's own pod autoscaler's pace, in every run from omni-v16's first on: the kind tests and the cloud sets alike (`scripts/kind_bench.sh`, `OMNI_INTERVAL`), the fast checks every 5 s as before. A window in which the governor made no write still needs its decisions to count, now one every 15 s. Runs before omni-v16 stand at the 60 s they ran at; nothing is read across engines.

66.52 Amendment (2026-10-22, omni-v17, written before any run of it): the main engine every 60 s, the beat a dial

On the founder's word of 22 October, afternoon, the heartbeat is a dial (`docs/OMNI_V17.md`): the main engine takes its full decision every 60 s, and any beat may be set (5, 15, 30, 60, 75, 90, 120 s and every value between), each shown beside native with what it buys and what it costs. From omni-v17's first run on, every run of this preregistration, the kind tests and the cloud sets alike, decides every 60 s by default (`scripts/kind_bench.sh`, `OMNI_INTERVAL`), the fast checks every 5 s as before; every clock counts seconds since omni-v16, so a give-back trial still lasts its 20 minutes, the wait after a breach its 3 minutes, and one machine is given back at most once a minute. The beats other than 60 s are read in their own runs (`docs/PACE_PREREGISTRATION.md`, amendment 3). Runs on omni-v16 stand at the 15 s they ran at; nothing is read across engines.

66.53 Amendment (2026-10-24, written before any run of it): Google's and Amazon's sets to the cap under the same stopping rule

On the founder's words of 24 October ("code it to wire it the same way that the Azure is running"), the Google and Amazon sets (`scripts/google_queue.txt`, `scripts/amazon_queue.txt`: the steady set, the bursts `1 4 1 6 1 9` and `1 6 1 8 1 6`, the real day on 1 to 9) run as Azure's do under the amendment of 19 October: up to 100 paired repetitions a run, the stopping rule's looks at 10, 20, 40 and 70 (`gke-metered.yml` and `eks-metered.yml` input `stop_looks`, `tools/stop_rule.py`, the same 99% intervals, never stopping on a LOSS), and "to the cap, stopping rule" in each run's title so their A, B and C are counted from zero. Everything else is as written for them: the arms, the loads, the windows, the machine families (`e2-standard-2` in `us-central1-a`; `m5.large` in `us-east-1`), the tune-down on the machines alone and the 60 s beat of the amendment above. Both queues are switched off and neither cloud has run a set on any engine since omni-v10's logins of 18 October; this is written before the first.

66.54 Amendment (25 October 2026): the ladder is 1, 10, 100 and 500

The founder's order of 25 October: the grid's top rung is 500 copies and 500 runs, in line with the Python's 500-run Monte Carlo (`tools/engine_runs.py`), replacing the 1,000 tier of 15 October. Every grid run started from this amendment on runs the ladder 1, 10, 100 and 500 (`scripts/dispatch_grid.py`); runs started before it stay as their own record. Paid cloud and GPU runs stay at 1, 10 and 100 copies with at most 100 repetitions.

All patents, copyrights and trademarks filed in the USA.

66.55 Amendment (31 October 2026, written before any set at the max starts): every cloud set runs the whole engine at the max; the machines alone of 14 October struck

The founder's words of 31 October ("Why is there any hard rule written ... Whatever the math does and falls out is whatever happens. All we need to do is tune up what the math does to the best way we can and let whatever falls out fall out. And when it falls out wrong, the tuning is wrong"; "What I care is to make the cloud the best it can be with Omni-Compass in it, as well as on site with Omni-Compass on it, and we have to sit and tune and tweak both scenarios"). The section "In the cloud, the machines alone" above is struck from this amendment on: no set started after it runs `OMNI_MACHINES_ONLY=1`, `dial save` or the governor's `--give-back-only` (the switch is gone from the rig and the workflows; the flag leaves the governor with the next engine version, and nothing passes it). Every cloud set runs Omni-Compass on top at the max, every muscle: the service sensed and its pod target moved inside the autoscaler's cover, the processor conveyed, the declared power model read, the replica room read live as on kind (`replica_ceiling` empty), and the machine lever parking and waking machines the cloud's own autoscaler made; the autoscaler, native's machine controller, stays in every arm and alone adds machines (`scripts/kind_nodepool.sh` asks the cloud for none). The bill (machine-hours at list price) is read by the one key beside work, response time, failures and alert minutes, and the cloud's judged number is the work per dollar: the work answered within the line for each dollar of the bill. The bill may rise where the work rises more, a rise read as power given beside the work it bought; a tune whose work per dollar falls against native is not admissible (`docs/THE_TUNE.md`), a fault of the tune, root-caused in the model first (`tools/model_gate.py`, whose cloud setting is the max from this amendment); the founder's order of 18 October, never raise its bill, is read the same way, by judging, never by tying the engine's hands. Every set at the max is its own A, B and C under the stopping rule of 19 October and the cap of 12 October (100 paired repetitions; 1, 10 and 100 copies); the sets started before this amendment (omni-v18's steady set; omni-v21's steady set, 25 of 100 repetitions when this was written) finish as the tune-down's record and are read in no table with a set at the max. Google's and Amazon's queues carry the same change behind their switches.

The same evening, before any set at the max started (the founder's words: "We never make the bill smaller ... they're looking to do more work with the money they're spending"; and then, "We're pushing 1% more bill, but we're getting ~12% more work ... anybody will pay 1% more for 10% more product"): the cloud is judged by its work per dollar, and these sets cannot read it as built. Each sends a fixed rate of requests (`LOADGEN=open`), so its work is the same in both arms by design and a set at the max could show only the bill beside a faster answer; the factory beat's ladder on omni-v23 reads the cloud setting at the max with the machine-hours up 9% to 35% across the beats, 14% at 60 s, on a plant whose work is fixed the same way (`results/model_gate/V23_LADDER.md`, our own models, class S; a note of 2 November: that ladder ran on the model's faulty stand-in, which amendment 6 of `docs/PACE_PREREGISTRATION.md` corrected the same night, and on the corrected model the cloud's setting at the max reads the machine-hours up 8% to 34% across the beats, 15% at 60 s, `results/model_gate/V23_LADDER_CORRECTED.md`: the point stands, a bigger bill for work held fixed). Azure's queue is held (`scripts/azure_queue.txt`,

All patents, copyrights and trademarks filed in the USA.

`switch=off`) until its sets carry the load whose work grows with the speed (the work meter, `LOADGEN=meter`, `tools/capacity_report.py`, the completed work counted in each arm), written into this preregistration before the switch goes on; then its sets start as written here, on the engine that stands then.

66.56 Amendment (31 October 2026, night, written before any set with the work meter runs): the cloud's sets read the work per dollar

The founder's words of 31 October, evening: "We're pushing 1% more bill, but we're getting ~12% more work ... anybody will pay 1% more for 10% more product". The cloud is judged by its work per dollar: the work answered within the line for each dollar of the bill, both from the same run.

- **The load.** Every cloud set runs the work meter (`LOADGEN=meter`, `deploy/kind/loadgen-meter.yaml`): one open-loop generator on the system pool's machine, off the measured workers, stepping through rising rates and counting every answer (inside the line, late, failed, not sent), the same rates in both arms; its warm-up requests are not counted. The meter was kind's (`docs/CAPACITY_PREREGISTRATION.md`); `scripts/kind_bench.sh` now runs it in a cloud as well, and every cloud workflow takes the load (`loadgen`) and the meter's rates (`rate_steps`) as inputs and names a meter set by its rates.
- **The readings.** Beside the bill (machine-hours at list price), the receipt reads the work inside the line a second and the work per dollar of the bill (`tools/live_reps.py`), each run's paired difference and its interval, and over A, B and C the three readings of `tools/confirm_abc.py`: the work aims higher (a rise GAIN, a fall LOSS); the work per dollar is work bought with a resource (a rise GAIN, a fall power given); the bill a resource spent (a rise power given, never a LOSS by itself). Every other gauge is read as in every set, losses included.
- **The rates, frozen on one tuning case** (as the capacity test's, its amendment 1): before the counted set, one tuning case at the max on the steady set's machines, one paired repetition, the rates 10 20 40 60 80 100 120 140 a second over 1,200 s, never counted, shows where native and Omni-Compass saturate on Azure's machines (`scripts/azure_queue.txt`, its first line, run once: `runs=A`). The counted rates are then written here as an amendment, from below what native serves inside the line to above what Omni-Compass serves, before the counted set's run A.
- **The counted set.** A, B and C, each up to 100 paired repetitions under the stopping rule of 19 October, at the max, on the engine that stands when each run starts; its looks read the work per dollar.
- **Order.** Azure's queue is switched on again with this amendment, the tuning case first; it starts once the queue's machine family is free (the omni-v21 steady set already running finishes first). The four sets of the open load wait behind the meter's, each on the founder's word. Google's and Amazon's queues carry the same change behind their switches.

66.57 Amendment (31 October 2026, night, written before any counted set with the work meter runs): a cloud set must show that Omni-Compass holds

On the founder's words of 31 October, night ("We don't have to show benefit. We know that. We just need to show we hold, and then we know where the benefit lives, and we can explain"), the claim every cloud set of this preregistration is read for is that Omni-Compass holds through the cloud (`DISCLOSURES.md`, section 10; `tools/places.py`): every judged gauge (the work done, the response time, the minutes over the line, the pods waiting, the failures) reads STEADY or GAIN against native by the one key, in each of runs A, B and C as each run's own word reads it. The bill, the machine-hours and the energy are resources, read beside it (a rise power given, never a LOSS by itself), with the work per dollar beside the bill (the amendment above). A set holds when its runs read no LOSS; a LOSS is root-caused and fixed in the model first, as everywhere. The benefit is not this set's claim: it is shown where it lives, at the software end, and explained through the wire. Nothing else about the sets changes.

66.58 Amendment (31 October 2026, night): the Omni index scores the software end; energy that no meter read is shown, never scored

where Omni-Compass holds). The index's headline scores from this amendment work, speed and machines, the software end's own results; energy is scored only where a meter read it (class P: the card's own meter). On kind and on the data stores no meter is read (a declared power model's watts; the host's processor seconds), so their energy is a model's estimate about the chip: shown in every row and scored as native's, the same juice, never dropped, because a geometric mean of fewer measures would weigh the rest more and read higher with nothing gained (`tools/omni_index.py`). No run changes and no table is read again: the same three-run tables give both readings, and the reading of 4 October, every measure scored, is printed beside the headline. Read from the tables that stand (omni-v21's): the headline GAIN, up 5.0% (the reading of 4 October: GAIN, up 5.2%); the service reading (work and speed alone, declared 9 October) unchanged, GAIN, up 12.9%.

66.59 Amendment (4 November 2026, written before the second tuning case and before any counted set with the work meter runs): both arms enter the window with the autoscaler reading; the rates read again lower

The tuning case of 31 October ran on 4 November (run 41745105583, omni-v25, one paired repetition, never counted). What its own files show, both read before anything below was written:

- **The two arms did not start from the same state.** Each arm runs on a cluster created minutes before its window. Native's autoscaler read the service from the start and entered the window at 5 copies (`capture.csv`: 5 current, 5 desired at 0 s); the Omni-Compass arm's autoscaler held no reading for its

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

first two and a half minutes (1 current, 0 desired until 206 s), so that arm served 1 of the first step's 1,501 requests inside the line and failed 1,481, where native served 301 and failed

229. The cause is the rig's, not the engine's: a managed cluster's metrics come up after the cluster does, and nothing waited for them.

- **The rates were too high for these machines.** At 40 requests a second and above both arms failed nearly everything; at 10 and 20 a second native served about 4 a second inside the line with its autoscaler at its cap of 10 copies, and Omni-Compass, raising the replica room to 35 copies by the window's end, served little more after its late start. No counted rates can be set from this run: below what native serves inside the line there is no step, and above it no arm served.

So, before any further cloud set: (1) on a managed cluster the warm-up starts only once the service's autoscaler holds a current reading, up to 300 s, the same in every arm, and the wait is written to the arm's `preflight.txt` (`scripts/kind_bench.sh`); kind is unchanged. (2) A second tuning case, run once and never counted, on the same machines, at the max, one paired repetition over 1,200 s, at the rates 2 4 6 8 10 12 16 20 a second (`scripts/azure_queue.txt`, its second line, `runs=A`). The counted rates are then written here, from below what native serves inside the line to above what Omni-Compass serves, before the counted set's run A, as the amendment of 31 October says. Nothing else changes: the counted set, the stopping rule, the readings and the claim that a cloud set must show that Omni-Compass holds stand as written. The four sets of the open load wait behind the meter's; the founder's words of 4 November ("All the clouds. Especially the clouds") are their word to start, and each starts once the meter's counted set has its three runs, the order the amendment of 31 October gives.

66.60 Amendment (8 November 2026, written before the counted set with the work meter runs): the counted rates, frozen on the tuning cases

The second tuning case ran twice, once on each engine that stood when the queue started it (run 41914478995 on omni-v25, 4 November; run 42408759289 on omni-v26, 7 November), each one paired repetition at the max over 1,200 s at the rates 2 4 6 8 10 12 16 20 a second, never counted. Both arms entered the window with the autoscaler reading (the amendment of 4 November). The share of each step's requests answered inside the line (500 ms), read from each arm's own `work_meter.json`:

Rate a second	2	4	6	8	10	12	16	20
native, run 41914478995	96%	94%	95%	85%	88%	78%	23%	19%
Omni-Compass on native, run 41914478995	99%	98%	94%	97%	94%	97%	92%	86%
native, run 42408759289	93%	96%	94%	90%	92%	76%	27%	19%
Omni-Compass on native, run 42408759289	95%	91%	94%	86%	77%	92%	81%	88%

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

By the work meter's own capacity rule (`tools/capacity_report.py`: the highest rate before the first step with fewer than 95% answered inside the line or more than 1% failed), native served 2 and 0 a second, Omni-Compass 4 and 2. So the counted rates are the second tuning case's, **2 4 6 8 10 12 16 20 a second over 1,200 s**: they start at native's capacity and reach five times Omni-Compass's, as the amendment of 31 October asks (from below what native serves inside the line to above what Omni-Compass serves). Read plainly, native's answers fall away above 10 a second (under 80% inside the line at 12, under 30% at 16 and 20), while Omni-Compass still answered 86% to 88% inside the line at 20 a second; the range may therefore not reach the rate at which Omni-Compass saturates, so the work it reads above native's is a floor of what it serves, never more. Nothing else changes: the counted set is A, B and C, each up to 100 paired repetitions under the stopping rule of 19 October, at the max, on the engine that stands when each run starts; its looks read the work per dollar of the bill in place of the bill, a rise GAIN and a fall power given, and the work inside the line falling is harm that keeps the set running, beside the 95th percentile and the failed requests (`tools/stop_rule.py`, as the amendment of 31 October, night, wrote it); the claim is that Omni-Compass holds (every judged gauge STEADY or GAIN in each run's own word). The set's line is added to `scripts/azure_queue.txt` with this amendment; the four sets of the open load still wait behind it.

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

CHAPTER 67

The Pod Start Wait on One Shared Host

One row of the Kubernetes add-on test read LOSS on the engines that stood on 18 October: the mean wait for a serving pod to start under KEDA's HTTP add-on. This page is that row's root cause, measured from the runs' own files. It sets out the mechanism and its exact decomposition, says what it predicts on a fleet of separate machines, and records the rig amendment that takes the test machine's own limit out of both arms. The engine is not changed. The row is never cut: every table that read it stands as recorded, and every page names it.

67.1 The row

The test (`.github/workflows/kind-addons.yml`, `docs/K8S_COMPASS_PREREGISTRATION.md`) runs native as KEDA with its HTTP add-on. In the http setup the add-on scales php-apache on the requests in flight. The omni arm is Omni-Compass on top of the same. On omni-v10, the three-run table of the http setup read the mean pod start wait **LOSS in all three of our runs** (+13.0%, +14.1%, +21.1% a pod). In the same three runs the total start wait read STEADY, pods started fell 24%, the response time fell 57% (mean) and 72% (95th percentile), and CPU used rose 50 to 54% (power given). On omni-v11, two runs of the same setup have landed. The third runs to its end on the rig it started on. Under the other setup, both (the CPU target and the requests in flight), the mean pod start wait,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

pooled over the repetitions, was lower in the omni arm on both engines (−7.8% on omni-v10, −6.3% on omni-v11; section 67.3).

67.2 What a pod start is made of

From Kubernetes' own timestamps in each repetition's pod watch (`pod_watch.json`), every serving pod created and made Ready inside the measured window splits into three phases:

- **scheduling**, created → PodScheduled: the scheduler's choice of a node.
- **node side**, PodScheduled → container running: the kubelet, the pod's sandbox and network, and the image.
- **app and probe**, container running → Ready: php-apache's start and its readiness probe (TCP on port 80, every 2 s).

`tools/pod_phases.py` reads them and places each start by two things: the host's busy share over that start (`host_cpu.csv`, the real machine under kind) and whether its node already carried a Ready serving pod when the pod was created. The receipt is `results/live/POD_START_PHASES.md`: 741 starts in five runs, three on omni-v10 (39108180989, 39115242861, 39123583570) and two on omni-v11 (39148024948, 39157778756). Kubernetes stamps these times in whole seconds, so one start is read to ±1 s and the ranges below are over every stratum holding more than one start:

Phase	Node already serving	Empty node
scheduling	0.00 to 0.02 s	0.00 to 0.20 s
node side	0.72 to 0.94 s	6.94 to 11.86 s
app and probe	0.49 to 0.86 s	0.40 to 0.91 s

The whole difference is the node side on an empty node. php-apache runs `registry.k8s.io/hpa-example`, named without a tag, so its pull policy is Always. On a node that already serves, the kubelet asks the registry for the image's digest, finds every layer on the node, and starts the container in under a second. On a node that never served, it downloads the image and unpacks it, and that takes 7 to 12 s.

67.3 Why the omni arm's starts took longer: the exact decomposition

Let s run over strata, each a band b of the host's busy share (0 to 0.5, 0.5 to 0.7, 0.7 to 1) paired with the node's state (empty or already serving). For arm a, let p[a,s] be the share of its starts in stratum s and W[a,s] their mean wait. Then the change in the mean wait splits exactly in two:

$\Delta W = W[\text{omni}] - W[\text{native}] = \Sigma_s\,(p[\text{omni},s] - p[\text{native},s]) \cdot W[\text{native},s] + \Sigma_s\, p[\text{omni},s] \cdot (W[\text{omni},s] - W[\text{native},s])$

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The first term is the shift of starts into other strata, a busier host or an empty node. The second is the wait at the same host load on the same kind of node. Where native has no start in a stratum, the first term takes the omni arm's own wait there ($W[native,s] := W[omni,s]$), and the two terms still add to $\Delta\bar{W}$ exactly. `tests/test_pod_phases.py` checks the identity on a constructed run.

Engine, setup	Native $\bar{W}$	Omni $\bar{W}$	$\Delta\bar{W}$	Shift into other strata	Same stratum
omni-v10, http	8.52 s	9.94 s	+1.42 s (+16.7%)	+1.57 s	−0.14 s
omni-v11, http	8.62 s	9.27 s	+0.65 s (+7.6%)	+1.64 s	−0.98 s
omni-v10, both	2.64 s	2.43 s	−0.21 s (−7.8%)	−0.35 s	+0.14 s
omni-v11, both	2.99 s	2.80 s	−0.19 s (−6.3%)	−0.26 s	+0.07 s

Under the http setup, every rise in the mean is the shift: 21 of the omni arm's 68 starts on omni-v10, and 11 of its 44 on omni-v11, began while the host was at least 70% busy. Native's starts never did. At the same host load on the same kind of node, the omni arm's starts were as fast as native's or faster (−0.14 s and −0.98 s). These numbers are pooled over the runs' repetitions, so they differ a little from the table's paired means. They are shown, never judged. The judged row stays the three-run table's.

67.4 The mechanism on one machine

A kind cluster is one machine. All seven nodes (a control plane and six workers) are containers on one 4-core GitHub runner, and they share its processor and its disk. Omni-Compass conveys idle processor to the serving pods: it raises their CPU limits in place. That is the work behind the response-time GAIN, and it shows as CPU used, power given. On kind, that processor is the same one on which every node unpacks an image. A pod placed on an empty node therefore unpacks its image on a processor that the conveyed pods on other nodes are keeping busy. Unpacking is processor and disk work, so it took longer: the node side on an empty node rose from 6.9 to 7.9 s with the host under half busy to 10.4 to 11.9 s with it at least 70% busy. omni-v7's shared-host guard (`omni_controller/capacity.py`) already holds every new raise while the runner is 75% busy or unread. It cannot move the unpacking off the processor the raises already granted are using.

67.5 What it predicts on a fleet of separate machines

This section is a prediction, not a measurement. On a fleet, each node is its own machine. A new pod's image is unpacked on its own node's processor, and the processor conveyed to pods on other nodes does not touch it. A pod placed beside pods already serving finds the image on its node and starts in about the time this rig measures for such a pod (1.3 to 1.7 s in total). So the coupling in section 67.4 is a property of the single machine. It is a test machine's limit, never Omni's result, and the row that showed it is reported as measured. The cloud sets (Azure now; Google and Amazon behind their $0 check) run every node on its own machine, and they measure it.

67.6 The amendment (2026-10-18): the served image pulled onto every worker before each arm

On kind, before each arm and before the governor starts or the window opens, `scripts/kind_bench.sh` applies an image pre-puller (`deploy/kind/prepull.yaml`). This is a DaemonSet with one pod on every worker, which pulls `registry.k8s.io/hpa-example` as an operator's image pre-puller does on a production fleet. The bench waits until the pre-puller's pod is ready on every worker, then deletes it. A pre-puller that does not finish on every worker fails the arm's checks, so the arm is marked invalid and never runs on the other rig. Each arm's `preflight.txt` records `images=pre-pulled on every worker before the arm` and the digest each worker pulled.

- **The same in both arms.** Every worker carries the image before either arm is told apart.
- **The operator's manifests are left as written.** `deploy/kind/demo.yaml` still names the image without a tag, so the kubelet still asks the registry for its digest at every start, in both arms. It then finds every layer on the node.
- **Not the engine.** No fingerprinted file changes: the pre-puller is the rig's, and it moved no engine's digest (`python3 tools/omni_version.py`).
- **Not the clouds.** On AKS, GKE and EKS every node is its own machine and unpacks on its own processor. Their sets keep `demo.yaml` and their rig as their A, B and C started.
- **Never two rigs in one table.** A kind workflow's run on omni-v11 counts toward its three only when the run's own commit carries the pre-puller (`RIG_FILE` in `scripts/dispatch_grid.py`, read from GitHub at that commit). That covers the core benchmark, the seven Kubernetes repetition sets, the large organisms, fixed capacity, KEDA's add-ons, CruiseKube, Goldilocks and the robustness pair. Their omni-v11 runs on the rig before run to their end, since nothing is cancelled, and stay as their own record. `tools/confirm_abc.py` reads the rig from every arm's preflight record and heads any table whose A, B and C ran on different rigs with that fact. The grid's squares with the real cluster inside count runs by protocol, carried in each run's name. This rig is protocol 4 (`KUBE_PROTOCOL`), and no omni-v11 run with the cluster inside had started on protocol 3, so all of theirs run on it.

67.7 What the next runs are expected to show (written before any of them)

On the amended rig, a serving pod on an empty node should start in about the time one beside a serving pod takes, about 1.3 to 1.7 s in both arms. The host's busy share should then stop deciding the wait. Whatever the three runs read is the reading. A LOSS is root-caused again and never cut.

67.8 Threats to validity, and what stays

- **Every worker carries the image**, including workers no serving pod would reach in a given repetition. That costs disk before the window and nothing inside it.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **The registry is still asked for the digest** at every start, in both arms (pull policy Always, as the operator wrote it). The round trip is inside the 0.72 to 0.94 s node side measured on nodes already serving.
- **The host still couples the arms' other work.** Conveyed processor still shares the runner with the kubelets, the probes and the load generator. omni-v7's shared-host guard and the window's refusal rules stand as before.
- **The batch jobs' small image** (`busybox:1.36`, about 4 MB) is still pulled on first use inside the window, as before. It unpacks in well under a second.
- **The model gate carries the old rig.** The conveyance model's pod start time (`start_time` in `tools/model_gate.py`: 8 s up to half busy, rising to 12.4 s near the top) was fitted to the omni-v6 KEDA run's 151 starts. That curve is the empty-node unpacking of section 67.4 in model form, and it is why the gate reads the pod start wait under conveyance LOSS (up 9.0%, a longer wait, on omni-v10 and omni-v11, `docs/OMNI_V11.md`). The curve is refit from the first amended-rig KEDA runs' own files, never guessed. Until then the model's start-wait row reads this coupling, not the governor.

CHAPTER 68

The 95th and 99th Percentiles: Where a Tail Reads Higher, and Why

The founder asked on 19 October why the 95th and 99th percentiles show a loss on the live page. This page answers from the receipts themselves. Every number is read from omni-v11's three-run tables (the engine that stood when this page was written) and from the raw files of their runs. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

Read with the tables that stand. This page reads omni-v11's tables of 19 October. On the newest tables (omni-v21) a tail does read LOSS in three tests, each named with its cause in `docs/LOSS_LEDGER.md`: CruiseKube's 95th percentile (Omni-Compass wrote nothing in any of its repetitions), the Redis small workload's 99th percentile, and MySQL as shipped, its burst's 95th percentile (one repetition of one run).

68.1 No tail reads LOSS

By the preregistered rule (a gauge reads LOSS only when it moves away from its aim in all three of our runs, every 95% interval clear of zero), **no 95th- or 99th-percentile row reads LOSS in any omni-v11 table** (23 tables), and none read LOSS in the omni-v10 tables before them. The one omni-v10 LOSS, the pod start wait under KEDA's HTTP add-on, was the test machine (an empty node unpacking the image inside the window); since the kind rig pulls the served image onto every worker before each arm, it reads STEADY on omni-v11 (`docs/POD_START_WAIT.md`, `results/live/V11_KEDA_REQUESTS.md`).

68.2 Real Kubernetes: Omni-Compass's tail was below native's in every repetition

The 90 paired repetitions of the three omni-v11 Kubernetes tests (Goldilocks, KEDA's HTTP add-on, KEDA on CPU and requests; ten pairs in each of runs A, B and C), each scored from its own raw files by `tools/live_reps.py arm_gauges`:

Test	Repetitions	Omni-Compass's 95th percentile above native's	99th percentile above native's	The 95th percentile, three-run reading
Goldilocks and the VPA	30	0	0	cut 61% to 64%, GAIN
Test	**Repetitions**	**Omni-Compass's 95th percentile above native's**	**99th percentile above native's**	**The 95th percentile, three-run reading**

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Test	Repetitions	Omni-Compass's 95th percentile above native's	99th percentile above native's	The 95th percentile, three-run reading
KEDA's HTTP add-on	30	0	0	cut 72% to 74%, GAIN
KEDA on CPU and requests	30	0	0	cut 52% to 53%, GAIN

68.3 Where a single run's tail rose: the data stores and the kill test

Six tail rows on omni-v11 have one or two runs whose interval lies wholly above zero. None holds in all three runs, so each reads STEADY; a page that colours each run's cell on its own shows them red.

Table, workload	Gauge	A	B	C	What it is
Kafka at the max, light	end-to-end latency, 99th percentile	+4.2% (+2.0 to +6.5)	−1.6% (−11.8 to +8.6)	−2.8% (−12.6 to +7.0)	one run up, two down: run-to-run variation
MySQL at the tune-down, read and write	latency, 95th percentile	+11.4% (+6.9 to +15.9)	−3.6% (−57.6 to +50.4)	+0.2% (−76.5 to +76.9)	one run up, the other two within wide noise
Redis at the tune-down, small values	latency, 99th percentile	+0.1% (+0.1 to +0.2)	+0.1% (−0.2 to +0.4)	+0.2% (−0.1 to +0.5)	about 6 µs on 5,600 µs, consistent in sign
Redis at the max, small values	latency, 99th percentile	+0.1% (−0.5 to +0.6)	+0.2% (+0.1 to +0.4)	+0.2% (+0.1 to +0.3)	the same
The governor killed outright mid-run (robustness)	response time, 99th percentile	+25.2% (+7.7 to +42.7)	−27.3% (−60.1 to +5.5)	−24.5% (−55.7 to +6.8)	one repetition of run A (below)
Redis at the max, the tuning workload	latency, 99th percentile	+0.3% (−0.0 to +0.5)	+0.2% (+0.1 to +0.2)	+0.0% (−0.2 to +0.3)	the same (the tuning workload, not counted)

The Kafka and MySQL rows are single-run excursions. In each, one run rose and the others fell or sat inside a wide interval; the three-run rule exists to keep such a run from being read as a result. On MySQL's read-and-write workload the three runs' intervals are ±4.5, ±54 and ±77 points wide: with three pairs a run, the test cannot resolve a tail change of under about 10% of native (`docs/POWER.md`).

All patents, copyrights and trademarks filed in the USA.

The kill test's row is one repetition. In nine of run A's ten repetitions both arms' 99th percentile is the probe's 10-second timeout. In the fifth, the omni arm's slowest answers reached 9.2 s 140 to 190 s after the kill, at the load's peak, with every setting already handed back to native's and both arms at the same ten replicas; the runner's processor was 100% busy for 70 s, and the second governor had started 50 s before on the same four cores. That is the likely cause, not proven (`docs/ROBUSTNESS_PREREGISTRATION.md`, "On omni-v11").

The Redis rows are a real, tiny, consistent rise: about 6 µs at the 99th percentile. Pooled over the 27 counted pairs of each set, Omni-Compass's 99th percentile is +5.8 µs (standard deviation 8.9 µs) at the tune-down and +7.1 µs (8.9 µs) at the max, while its mean latency falls about 32 µs (the larger ceiling turns misses into hits). The order of the arms does not explain it: with Omni-Compass running second the rise is +4.9 µs, running first +8.5 µs. The cause is examined in section 68.4.

68.4 The Redis tail: the harness's own layout, not Omni-Compass's effect on Redis

In the Redis harness (`tools/run_redis.py`) the brain runs as a thread inside the load generator's own Python process. Once a second it reads the last second's requests (twice rebuilding a list of about 1,500 of them under the application's lock), decides and writes its audit line. While it computes it holds Python's interpreter lock, so a request thread that wakes from its store-trip sleep at that moment waits before its clock is read. Omni-Compass in a deployment is its own process and never a thread inside the application it governs; only this harness puts the two together. The harnesses of the other data stores do not: Kafka's producer and consumers, pgbench, sysbench and YCSB all run as processes of their own.

The test (`tools/redis_brain_probe.py`, the record in `results/REDIS_BRAIN_PROBE.json`, class S). It runs the harness's own application at the GitHub rate (1,500 requests a second, 32 request threads), with and without the harness's own brain loop in the same process, paired, the order alternating. Two outside parts are stand-ins, the same in both arms. The store answers every request in a fixed 0.1 ms (a sleep, as a socket wait is), a hit with probability 0.6 and otherwise the declared 5 ms store trip. The plug writes nowhere, so the brain reads, decides and runs its trials while the cache never changes. The only difference between the arms is the brain thread computing in the same process (1.4 ms of processor a second).

With the brain in the process, against without (12 pairs of 20 s)	Change	95% interval	Pairs with a rise
response time, 99th percentile	+101 µs	+50 to +151 µs	10 of 12
response time, 95th percentile	+6.8 µs	+1.2 to +12.4 µs	9 of 12
response time, median	+2.1 µs	+0.2 to +4.0 µs	9 of 12
response time, mean	+5.4 µs	+2.9 to +7.9 µs	11 of 12

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

What it shows. The brain's presence in the load generator's process, with nothing else changed, lengthens the timed requests, most in the tail. In this stand-in the effect is larger than on GitHub's machines (+101 µs at the 99th percentile against about +6 µs), because the stand-in's store answers in a fixed time and its tail is narrow. Three findings agree with it:

- in the Redis set run with native as shipped, the brain is idle (the knob is at its limit on native, and it computes nothing), and the 99th percentile shows no rise of consistent sign (`V11_REDIS_SHIPPED.md`);
- the rise appears in both of the operator's sets, where the brain computes every second;
- the mean still falls in those sets, because the larger ceiling turns misses into hits.

The tail rise is the harness's layout, and it weighs against Omni-Compass, because only the omni arm carries the brain inside its process. A direct test on a real Redis on this machine (three pairs) could not resolve it: the arms differed by hundreds of microseconds from pair to pair, and it was replaced by the test above.

The fix. The harness runs the brain in a process of its own, as a deployment does. It changes how the omni arm is measured, so it lands with the next engine version and its reruns, never inside the omni-v11 tables (`docs/CHANGE_CONTROL.md`).

68.5 Why the live page showed red

The live page (`docs/engine/OMNI_COMPASS_LIVE_ENGINE.html`, rebuilt by its own workflow) reads each benchmark's newest table. Until the omni-v11 tables reached main it read omni-v10's, where the KEDA pod start wait read LOSS. It also shows each run's own interval beside the three-run reading, so a single run's rise, like those in section 68.3, can show as that run's own excursion even where the three-run reading is STEADY. With the omni-v11 tables on main (19 October), the page's only LOSS is gone, and its next rebuild reads them.

CHAPTER 69

How Small an Effect Each Test Can See

Generated by `python3 tools/power.py` from the newest three-run table of each benchmark that stores its rows (`results/live/V*_*.json`); `tools/power.py --check`, run by `verify.py`, fails a push where this page is not what the tables give.

A row reads **STEADY** when a run's 95% interval includes zero: the change is smaller than the test resolves, not zero. The columns say how small:

- **MDE, one run**: the smallest true change one run detects with 80% power (two-sided 5%).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **MDE, all three runs**: the smallest true change that reads GAIN or LOSS in all three of our runs with 80% power (each run at 92.8%).
- **Repetitions for 5%**: the paired repetitions a run would need for the three-run MDE to reach 5% of native.

Each figure is in percent of native's mean in the least favourable of the three runs. Every number is computed from the table's own intervals with the Student t quantiles the tables use (`omnicompass/student_t.py`).

69.1 All Four (omni-v26, `V26_ALL_FOUR.md`, 10 paired repetitions a run)

Measure	Reading	MDE, one run	MDE, all three runs	Repetitions for 5%
work inside the response line (requests a second; the capacity test's own gauge)	GAIN in all three of our runs	21.7%	26.7%	286
worker nodes in service, mean	STEADY, the same	0.0%	0.0%	1
node-hours	STEADY, under the floor (the three runs' mean 0.07%)	0.3%	0.3%	1
energy, parked workers still on at idle power (Wh)	STEADY, under the floor (the three runs' mean 0.07%)	0.6%	0.7%	1
energy (Wh)	STEADY, under the floor (the three runs' mean 0.07%)	0.6%	0.7%	1
response time (ms), mean	GAIN in all three of our runs	19.0%	23.3%	218
response time (ms), 95th percentile	GAIN in all three of our runs	19.4%	23.9%	229
response time (ms), 99th percentile	the runs disagree	49.4%	60.7%	1473
time over the response line (% of samples)	GAIN in all three of our runs	19.6%	24.1%	234
failed requests (%)	the runs disagree	9.9%	12.1%	59
alert minutes (whole minutes whose 95th percentile, failed requests counted over, was over the line)	GAIN in all three of our runs	14.7%	18.1%	131
pending pods, pod-minutes	shown, not judged	119.3 %	146.6%	8600
utilisation (used / allocatable)	shown, not judged	3.6%	4.5%	9

pods started	power given in all three of our runs	52.5%	64.6%	1668
pod start wait, total (s)	LOSS in all three of our runs	83.4%	102.4%	4198
pod start wait, mean (s)	LOSS by the mean of our three runs, beyond the noise in 0 of 3	40.9%	50.2%	1009
host CPU busy, the real machine under kind (%)	shown, not judged	2.6%	3.2%	5
host cores (the real machine under kind)	shown, not judged	0.0%	0.0%	10

69.83 What the STEADY rows mean

185 rows read STEADY. In 2 of them the test could not resolve a change under 10% of native in all three runs, so STEADY there means "no change larger than the MDE shown", and nothing finer is claimed.

CHAPTER 70

Every Change to Every Preregistration

Generated by `python3 tools/deviations.py` from the preregistrations in `docs/`; `tools/deviations.py --check`, run by `verify.py`, fails a push where this register is not what they give. Each amendment's reason, and what it changed, is written in the preregistration it amends; this register is the index to all of them, newest first. The timing is the amendment's own statement in its heading. Earlier windows, runs and tables keep the rule they ran under, and a three-run table never pools runs from either side of an amendment that changes what it reads.

101 amendments in 18 preregistrations: 81 before the runs it governs; 13 not stated in its heading; 7 after runs began.

Date	Preregistration	Amendment	Timing
2026-11-11	`docs/PACE_PREREGISTRATION.md`	Amendment 7 (11 November 2026, 07:20 UTC, written before any reading of its runs): the beat on a moving load, on the engine that stands	before the runs it governs
2026-11-08	`docs/K8S_COMPASS_PREREGISTRATION.md`	Amendment (8 November 2026, written before the counted set with the work meter runs): the counted rates, frozen on the tuning cases	before the runs it governs
2026-11-04	`docs/K8S_COMPASS_PREREGISTRATION.md`	Amendment (4 November 2026, written before the second tuning case and before any counted set with the work meter runs): both arms enter the window with the autoscaler reading; the rates read again lower	before the runs it governs
2026-11-01	`docs/GPU_PREREGISTRATION.md`	Amendment 16 (2026-11-01, declared before any run of it): the stacks with the card fully loaded	before the runs it governs

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Date	Preregistration	Amendment	Timing
2026-10-31	docs/SOLO_PREREGISTRATION.md	Amendment 2 (31 October 2026, written before the runs it governs): Omni direct keeps every muscle Omni-Compass cannot be	before the runs it governs
2026-10-31	docs/SOLO_PREREGISTRATION.md	Amendment 1 (31 October 2026, written before the runs it governs): the arm's pod writes were refused by the rig's own identity	before the runs it governs
2026-10-31	docs/PACE_PREREGISTRATION.md	Amendment 6 (31 October, night): the model's stand-in corrected; the ladder read again on it, in the cloud and on site	not stated in its heading
2026-10-31	docs/PACE_PREREGISTRATION.md	Amendment 5 (31 October, written before the ladder's cloud half runs on it): the cloud setting at the max	before the runs it governs
2026-10-31	docs/PACE_PREREGISTRATION.md	Amendment 4 (31 October, written before any reading of the ladder was seen): the factory beat read again on the engine that stands	before the runs it governs
2026-10-31	docs/K8S_COMPASS_PREREGISTRATION.md	Amendment (31 October 2026, written before any set at the max starts): every cloud set runs the whole engine at the max; the machines alone of 14 October struck	before the runs it governs
2026-10-31	docs/K8S_COMPASS_PREREGISTRATION.md	Amendment (31 October 2026, night, written before any set with the work meter runs): the cloud's sets read the work per dollar	before the runs it governs
2026-10-31	docs/K8S_COMPASS_PREREGISTRATION.md	Amendment (31 October 2026, night, written before any counted set with the work meter runs): a cloud set must show that Omni-Compass holds	before the runs it governs
2026-10-31	docs/K8S_COMPASS_PREREGISTRATION.md	Amendment (31 October 2026, night): the Omni index scores the software end; energy that no meter read is shown, never scored	not stated in its heading
Date	**Preregistration**	**Amendment**	**Timing**
2026-10-30	docs/YCSB_PREREGISTRATION.md	Amendment 6 (2026-10-30, declared before any run on it): the max on the cache, through	before the runs it governs

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Date	Preregistration	Amendment	Timing
		the server's own account of a miss (the next engine's candidate)	
2026-10-30	`docs/REDIS_PREREGISTRATION.md`	Amendment 5 (2026-10-30, declared before any run on it): the max on the cache's ceiling, with the working set's floor (the next engine's candidate)	before the runs it governs
2026-10-30	`docs/POSTGRES_PREREGISTRATION.md`	Amendment 4 (2026-10-30, declared before any run on it): the max on the pooler's pool (the next engine's candidate)	before the runs it governs
2026-10-30	`docs/MYSQL_PREREGISTRATION.md`	Amendment 6 (2026-10-30, declared before any run on it): the max on the buffer pool, through the server's own account of a miss (the next engine's candidate)	before the runs it governs
2026-10-30	`docs/KAFKA_PREREGISTRATION.md`	Amendment 4 (2026-10-30, declared before any run on it): the group's twin and the immune reflex (the next engine's candidate)	before the runs it governs
2026-10-30	`docs/GPU_PREREGISTRATION.md`	Amendment 15 (2026-10-30, the rig, declared before any counted run on it): the window opens once the governor stands	before the runs it governs
2026-10-25	`docs/ORCHESTRATORS_PREREGISTRATION.md`	Amendment 2: the Cluster Autoscaler acts after the scheduler's pass (written before the third run, 25 October 2026)	before the runs it governs
2026-10-25	`docs/ORCHESTRATORS_PREREGISTRATION.md`	Amendment 1: the response time and the pods waiting, corrected in the model (written before the second run, 25 October 2026)	before the runs it governs
2026-10-25	`docs/K8S_COMPASS_PREREGISTRATION.md`	Amendment (25 October 2026): the ladder is 1, 10, 100 and 500	not stated in its heading
2026-10-24	`docs/K8S_COMPASS_PREREGISTRATION.md`	Amendment (2026-10-24, written before any run of it): Google's and Amazon's sets to the cap under the same stopping rule	before the runs it governs
2026-10-22	`docs/PACE_PREREGISTRATION.md`	Amendment 3 (22 October, afternoon, written before any omni-v17 run): the beat a dial, the main engine at 60 s	before the runs it governs

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

Date	Preregistration	Amendment	Timing
2026-10-22	docs/PACE_PREREGISTRATION.md	Amendment 2 (22 October, written before any run): the founder sets the heartbeat at 15 s	before the runs it governs
2026-10-22	docs/PACE_PREREGISTRATION.md	Amendment 1 (22 October, written before any run): how rule 1 reads the model	before the runs it governs
2026-10-22	docs/K8S_COMPASS_PREREGISTRATION.md	Amendment (2026-10-22, omni-v17, written before any run of it): the main engine every 60 s, the beat a dial	before the runs it governs
2026-10-22	docs/K8S_COMPASS_PREREGISTRATION.md	Amendment (2026-10-22, omni-v16, written before any run of it): the full decision every 15 s	before the runs it governs
2026-10-21	docs/YCSB_PREREGISTRATION.md	Amendment 5 (2026-10-21, declared before any run on it): the machine's operating system, Linux 6.8	before the runs it governs
2026-10-21	docs/GROUP_PREREGISTRATION.md	Amendment 3: what the counted runs of OCM and Armada found (written after those runs, 21 October 2026)	after runs began
2026-10-20	docs/GROUP_PREREGISTRATION.md	Amendment 2: Armada, frozen (written before its first run, 20 October 2026)	before the runs it governs
2026-10-20	docs/GROUP_PREREGISTRATION.md	Amendment 1: Open Cluster Management, frozen (written before its first run, 20 October 2026)	before the runs it governs
2026-10-20	docs/CRANE_PREREGISTRATION.md	Amendment 1: what the trial found in the rig (written after the trial of 20 October 2026, before the counted runs)	before the runs it governs
2026-10-20	docs/BATCH_QUEUE_PREREGISTRATION.md	Amendment 9: what the trials of 20 October found in the rigs (written after the trials, before the counted runs)	before the runs it governs
2026-10-20	docs/BATCH_QUEUE_PREREGISTRATION.md	Amendment 8: the Gödel scheduler (written before its first run, 20 October 2026)	before the runs it governs
2026-10-20	docs/BATCH_QUEUE_PREREGISTRATION.md	Amendment 7: KubeRay (written before its first run, 20 October 2026)	before the runs it governs
2026-10-20	docs/BATCH_QUEUE_PREREGISTRATION.md	Amendment 6: the four ways (written before their first run, 20 October 2026)	before the runs it governs

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

Date	Preregistration	Amendment	Timing
2026-10-20	`docs/BATCH_QUEUE_PREREGISTRATION.md`	Amendment 5: the governor's own core (written before any run on it, 20 October 2026)	before the runs it governs
2026-10-20	`docs/BATCH_QUEUE_PREREGISTRATION.md`	Amendment 4: Koordinator's runs repeated on the kubelet's cgroup root its own tests use (written before they were repeated, 20 October 2026)	before the runs it governs
2026-10-20	`docs/BATCH_QUEUE_PREREGISTRATION.md`	Amendment 3: the Kubernetes scheduler alone, as shipped and with its bin-packing profile (written before its first run, 20 October 2026)	before the runs it governs
2026-10-20	`docs/BATCH_QUEUE_PREREGISTRATION.md`	Amendment 2: Koordinator (written before its first run, 20 October 2026)	before the runs it governs
2026-10-20	`docs/BATCH_QUEUE_PREREGISTRATION.md`	Amendment 1: the KAI scheduler (written before its first run, 20 October 2026)	before the runs it governs
2026-10-20	`docs/BATCH_QUEUE_PREREGISTRATION.md`	Amendment 11: KubeRay's two LOSS rows root-caused (written from the runs' own files, 20 October 2026, before any run on the engine that fixes them)	before the runs it governs
2026-10-20	`docs/BATCH_QUEUE_PREREGISTRATION.md`	Amendment 10: what the counted runs of 20 October found (written after those runs, before the Gödel runs start again)	before the runs it governs
2026-10-19	`docs/SWARM_PREREGISTRATION.md`	Amendment 2 (2026-10-19, before omni-v12's runs; written after the omni-v11 runs and the reflex study were seen, and said so)	after runs began
2026-10-19	`docs/K8S_COMPASS_PREREGISTRATION.md`	Amendment (2026-10-19): a worker held by an add-on's own mark while it serves is in service	not stated in its heading
2026-10-19	`docs/K8S_COMPASS_PREREGISTRATION.md`	Amendment (2026-10-19): a paid cloud set runs to its cap and stops when its bill is read (written before any run of it)	before the runs it governs
2026-10-18	`docs/K8S_COMPASS_PREREGISTRATION.md`	Amendment (2026-10-18, omni-v11): the governor holds on a reading with no machine in service	not stated in its heading

CHAPTER 71

Limitations and Threats to Validity

What the three-run tables can and cannot support (this page's counts were read on omni-v11's tables, the newest when it was written; omni-v25, which stood from 3 to 7 November, has its own three-run table of every test that had one on omni-v21, `results/live/V25_*.md`, and omni-v26, the engine that stands since 7 November, runs every one of them again), written the way a referee reads a study: who ran it, what could bias a comparison, what a gauge really measures, how often the reading rule could be fooled, and how far a result travels. Each limitation names what would remove it. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

71.1 Independence

- **Every run is ours.** The harnesses, the runs, the tables and this page are Dubra Software Inc. / The Omni-Compass LLC's own; no outside party has run, reproduced or reviewed them. What reduces the dependence on us: every table is rebuilt from its raw receipts by a public command and compared byte for byte (`tools/reproduce.py`, `reproduce.yml`), every rule was written before its runs (`docs/DEVIATIONS.md` lists every later change with its timing), and every raw file carries its SHA-256.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **What would remove it:** an outside party running the same workflows from a fork, or the paired protocol on its own system (`docs/PILOT_PROTOCOL.md`).

71.2 Internal validity: could something other than Omni-Compass explain a difference?

- **Pairing and order.** Each repetition runs native and Omni-Compass back to back on the same machine, alternating which goes first. With three pairs a run (the data stores) the order cannot balance (two to one). Where it was checked (the Redis tail, `docs/TAIL_LATENCY.md`) the difference held in both orders.
- **The machine moves between runs.** GitHub's free machines differ from run to run. On MySQL's update workload the throughput was up 0.3% in every pair of run B and down 0.4% in every pair of run C, so the row reads "the runs disagree": a machine-level effect larger than the change, under an offered rate that pins throughput near 98% of what is offered.
- **One machine under kind.** Every Kubernetes node in the kind tests is a container on one runner; the governor counts that machine's processor once (omni-v6) and the served image is pulled onto every worker before each arm (18 October). A multi-machine cluster (Azure) is the test of the cloud's own behaviour.
- **The measuring process.** In the Redis harness the brain runs as a thread inside the load generator's own Python process, and its once-a-second work shares Python's interpreter lock with the request threads. The 99th percentile there reads about 6 µs higher with Omni-Compass in two of three runs. A controlled test shows the cause: the brain's presence in the process, with nothing else changed, lengthens the timed requests (99th percentile +101 µs, 10 of 12 pairs; mean +5 µs, 11 of 12) (`docs/TAIL_LATENCY.md`, section 4). The bias weighs against Omni-Compass, because only its arm carries the brain, and no deployment runs the brain inside the application. The next version's harness runs it in a process of its own. The other data stores' load generators already run as processes of their own.
- **Simulators that do not reproduce exactly.** CityLearn's comfort score moved by up to 3.6×10^{-5} between runs in both arms alike; PyBullet (the drone swarm) reproduces to about one part in a thousand across GitHub's machines. Rows that do not reproduce read "the runs differ", and the tables say when the paired change was exactly zero.

71.3 Construct validity: does each gauge measure what its name says?

- **Energy in the Kubernetes and swarm tables is a declared model**, not a meter (evidence class S inside a live test). The only physical meter that has read Omni-Compass is the card's own (class P, the Lambda runs, `results/gpu/`); no meter at the wall or on a server's own power has, so less energy there is **undetermined**.
- **Node-hours on kind are not a bill.** The cloud bill is measured only in the cloud (Azure, running).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **The modelled muscles and organisms are our own models** (class S): 1,107 muscles, 530 GAIN, 0 LOSS (`results/realms_v5/REALMS_V5.md`, read again by the one key on 24 October) say what our models do, never what a real plant does.
- **A margin no gauge judges, and a fault it hid.** In the drone swarm the judged safety gauge is the near miss (two drones under half the 0.3 m keep-out, 0.15 m). The closest approach is shown, not judged. With Omni-Compass on top it fell from about 0.30 m to as low as 0.156 m (run C, the short cell). There was no near miss and no collision in any counted run, but the margin native keeps was spent to fly faster. On mission draws outside the preregistered seeds it read LOSS: on the mixed cell with draw 214, the omni-v11 wire let two drones come within 0.083 m, with 5 near-miss ticks and 3 collision ticks, where native flew the same draw with none (`results/model_gate/V12_SWARM_REFLEX.md`). A preregistered set of seeds could not show it, and only flying draws the wire was never tuned on did.
- **The cause is in the wire, not the brain.** The proximity reflex is written to return the planner's cruise at once. The code lowered the speed by 0.01 a tick instead, so a drone that saw a neighbour within 0.5 m flew fast for about a second more.
- **The fix**: the reflex at once, reaching out with the square of the speed, as the stopping distance does. In our own flights it held every drone at or outside the full keep-out (the least, 0.304 m), with no near miss and no collision, on all ten cells and draws tried, the four preregistered cells and six untouched draws. It kept 49% to 92% of the energy cut.
- **What came with it.** The fix landed in omni-v12 (`docs/OMNI_V12.md`), and the same version's preregistration amendment (`docs/SWARM_PREREGISTRATION.md`, amendment 2, written before its runs) makes a collision with Omni-Compass on top a judged LOSS row, voids a cell only when native itself collides, and adds three mission draws no wire was ever run on.

71.4 Statistical conclusion validity: how often could the reading rule be fooled?

- **The three-run rule is strict.** A row reads GAIN or LOSS only when three separate runs all move the same way with every 95% interval clear of zero. With no true change, and runs independent, one run's interval is clear of zero on a given side with probability 0.025, so a false GAIN or LOSS in a row has probability $2 \times 0.025^3 \approx 3.1 \times 10^{-5}$. Over the 1,039 judged rows of the omni-v11 tables the expected number of false readings is at most 0.03. Of those rows, 613 are in tests that carry noise; the other 241 are in deterministic simulators, which reproduce to the digit. Over the 613 the expectation is 0.02. Runs share the harness, so they are not fully independent of it; the number is a guide, not a guarantee. These counts were read before the one key of 24 October: since then a mean change of 0.5% or more reads its word **by the mean of our three runs**, with the count of runs beyond the noise beside it, so a row can read GAIN or LOSS without every interval clear of zero; only a row that reads **in all three of our runs** carries the strength computed here (`docs/HOW_TO_READ_THE_RESULTS.md`).
- **STEADY is not zero.** A row reads STEADY when the test could not resolve a change; `docs/POWER.md` gives, for every judged row, the smallest change all three runs would detect. Many

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

data-store rows (three pairs a run) cannot resolve a change under 10% of native; STEADY there means "no change larger than that", and nothing finer is claimed.

- **Rows where the runs disagree** (omni-v11): MySQL's update throughput (above), CityLearn's comfort score in two districts (CityLearn's own drift; the paired change exactly zero), and the drone swarm's closest approach, tracking error and cruise override (PyBullet's reproduction; the first is the margin of section 71.3, the other two are shown, not judged).
- **A fixed set of seeds is a sample, not a guarantee.** Every preregistered test runs on seeds written before its runs, so a reading holds for those draws. The swarm's collisions (section 71.3) appeared only on a draw outside them. The swarm's omni-v12 runs add three draws never flown (amendment 2); the other tests still run on their fixed seeds alone.

71.5 External validity: how far does a result travel?

- **Loads.** Open-loop load generators on synthetic schedules, one public day of demand (Google 2011) on kind, and the data stores' published benchmark workloads (sysbench, YCSB, pgbench). No production traffic.
- **Size.** kind clusters of six workers on one machine; an Azure cluster of four workers. No large production fleet.
- **Undetermined:** the cloud bill (Azure running, Google and Amazon gated by their $0 checks), energy (no meter), the GPU (no run on the engine that stands), production readiness (no deployment). These are written as undetermined wherever they appear, never as results.

71.6 The engine changed often

Twelve versions in twelve days (omni-v5 to omni-v16, `docs/CHANGE_CONTROL.md`), each through omni-v15 a fault found in a real run and fixed, and omni-v16 the decision pace made a clean setting on the founder's word. No table mixes engines, and each benchmark runs again on every version; the cost is that each version's three-run tables take a day or more to land, so the newest tables of some benchmarks are an older engine's until they do.

CHAPTER 72

The Evidence Ledger

Every material statement in the technical package gets exactly one primary evidence class. A statement never borrows a stronger class from the one printed beside it.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Class	Meaning	Layer
T	formally proved theorem, under stated assumptions	L1 mathematical mechanism
V	finite computational verification: exact over a declared finite set, never a theorem beyond it	L1
S	our own model's result (modelled; never offered as proof)	L2 modelled systems
L	live observation of external software (a real Kubernetes API, a real process)	L3 external software
P	independent physical measurement (a meter Omni does not read or control)	L4 physical plant
O	open: not established	—

No layer stands in for another: a theorem is not a physical validation, a Monte Carlo result is not a theorem, and a model's energy is not a meter's.

Mechanism identity for every row: `results/MECHANISM_IDENTITY.json`. Canonical engine `symmetric_verified`, mechanism id `b10f1b4128ff…`; the printed configuration `printed_eight_line`, id `623934cc31e9…`, is a named alternative (Option A of the directive: one canonical, one alternative embodiment; no equivalence is claimed).

72.1 Layer 1: the mechanism

Class	Statement	Where
T	Unsaturated, the U-channel error obeys $de/dt = -KP\,e$; $V = e^2/2$ has $dV/dt = -KP\,e^2 < 0$ for $e \neq 0$ (inside Omega_unsat only).	`docs/TRACKING_THEOREM.md` Thm 1
T	With the U drift bounded by F[bar] < u[max], V decreases wherever $e \neq 0$, saturated or not; e never changes sign; saturated stretches end in bounded time (continuous time).	Thm 2
T	On the declared parameter box, F[bar] = 16.86 < 25, so Thm 2 holds over the whole box in continuous time.	Thm 2

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Class	Statement	Where
T	The sampled controller (u held through each RK4 step) satisfies e_(k+1) = 0.88 e_k + d_k, hence abs(e_k) <= 0.88^k abs(e_0) + epsilon_h (1 − 0.88^k)/0.12.	Thm 3
V	epsilon_h = 0.00378 over every micro step of the 500 frozen fixtures (nearest target); ultimate bound 0.0315 < BASIN_TOL 0.10. Wrong target: 0.0243, bound 0.20 (wider than the basin).	`results/TRACKING_BOUNDS.json`
V	The discrete execution dithers inside that band: abs(e) grew on 27 061 of 100 000 micro steps; e changed sign 747 times. The continuous monotone decay is not inherited.	same
V	Saturated micro steps: 0 of 100 000 (nearest target), 5 of 100 000 (wrong target).	same
T	The admissible box A (E interval, abs(U − sigma) <= abs(U0 − sigma), S between S0 and S[plus]) is forward invariant in continuous time.	Thm 4
V	Discrete invariance of A: 0 failures over 100 000 micro steps of the frozen fixtures, both targets.	`results/TRACKING_BOUNDS.json`
T (conditional, computer-assisted)	The later executed-RK4 proof claims E1–E2, S1, I1 and U1–U5 over their **declared admissible parameter/start box**, with SMT and outward-rounded interval enclosures; U enters an error ball with radius at most 0.0677. This supersedes the older blanket whole-box-open label **only for these explicitly named obligations** and still requires independent certificate rerun.	`docs/ENGINE_PROOFS.md`; `docs/TRACKING_THEOREM.md` §3–4

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Class	Statement	Where
T (conditional, computer-assisted)	Bath mode B1 has spectral radius at most 0.99995 under the stated stable linear forcing hypotheses; boundedness is conditional, and no numerical amplitude ceiling or full-system convergence follows.	`docs/ENGINE_PROOFS.md` B1
O	CERT-10 for **every** admissible initial state (the certified worst-case entry argument currently guarantees nine macro dwell steps), initial states below S–, and unrestricted closed-loop external-plant stability.	`docs/ENGINE_PROOFS.md` §5
O	Global stability of the forced six-state system.	`docs/FORMAL_STATUS.md`
V	500 / 500 frozen fixtures satisfy CONVEY-5 and CERT-10 (dwell predicates, not external certification).	`results/core_evidence.json`
V	Frozen 500-fixture comparison: symmetric_verified final error 7.48e-5, integrated abs(u) 0.878, peak 13.93; printed_eight_line 5.13e-6, 11.79, 18.87. Both executable; not interchangeable.	`results/MECHANISM_IDENTITY.json`
V	Python and C++ produce identical results (engine, governor, shield, HPA law, conveyance, GPU rules); twins sealed.	`verify.py`, `results/SEAL.json`

72.2 Layer 2: our own models

Class	Statement	Where
S	Synthetic stack: energy for Omni over the Kubernetes reference 168.9 → 121.7 kWh per run (documented-behaviour reference, not upstream controllers).	`docs/CLAIMS_REGISTER.md` C8

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Class	Statement	Where
S	Fleet harness, recorded PlanetLab shapes: energy down 40.6% vs HPA+CA and down 21.7% vs Karpenter-lite, a cut (omni_fleet).	C17
S	Single GPU physics model: the engine alone would save 10.6–13.6% work per kJ on card A but breaks the p95 guardrail by 15–28%; with the frozen guards, about 1% to 5% more work per kJ inside it.	`results/gpu/sim/FINDINGS.md`
S	Node exchange (CPU and GPU on one budget): 1.4% to 5.7% more work against the separate budgets, never over budget.	`results/hardware/NODE_EXCHANGE_*.json`
S	Six organisms (345, 262, 282, 337, the four stacked 1,226, the whole tower 656), the compass law on every muscle against each organism's own controllers, 1,000 paired runs at 1× and 10× size, before round 6: work per energy up 0.20% to 0.30%, energy down 0.21% to 0.32%; every knob handed back.	`docs/HISTORY.md` (the grid's file since written again)
S	The six organisms on Omni v3 (430, 376, 470, 440, the four stacked 1,716, the whole tower 945), 1 to 1,000 paired runs at 1 to 1,000 copies: work per energy up 0.06% to 0.40%, a little more work for each unit of energy (under the 0.5% floor of the one key, so STEADY by it); time over the service line lower than native's in every cell; every knob handed back.	`results/scale/GRID.md`
S	GPU card model, the card's firmware alone against the firmware with Omni on top (amendment 8: the verdict, 2% allowance), geometric means over 10 seeds and 10 fresh seeds, raw changes: AI token generation, energy −3.25% / −3.72% (less energy), median +0.55% / +0.70% and p95 +0.29% / +0.26% (slower); compute-bound, energy −0.70% / −0.48%, median +1.56% / +1.47%. A fixed 105 W power cap alone against the cap with Omni on top: energy −2.09% / −2.37% (AI token generation). Written on	`results/sim/gpu_two_wire/RESULT.md`

All patents, copyrights and trademarks filed in the USA.

Class	Statement	Where
	5 October under an earlier engine; it stands on no engine since (`docs/engine/APPRAISAL.md`, item 5).	
S	Realm harness round 3 (every realm carries the shared spine), preregistered, seeds 3000-3009: the whole 656-muscle tower native against one brain on top, work per energy up 0.1% (raw +0.1 to +0.1), violations up 0.5 pp, its label of that day SUPERIOR WITHIN GUARDRAILS. Realms: Energy up 0.2% with violations up 1.9 pp (a trade); Compute 0.0% with violations up 2.1 pp (not established); Distribution down 0.1%; Physics down 0.7%. Rounds 1 and 2 kept, superseded.	`results/realms/REALMS.md`
S	Stacked organism (round 4, seeds 4000-4009): the four realm organisms on one clock, 1,226 muscles with every duplicate; stacked native equals the four realms alone on every seed. One brain over the stack: energy down 0.14%, work per energy up 0.02%, violations up 1.4 pp, its label of that day ENERGY IMPROVEMENT WITH SERVICE TRADEOFF; four separate brains about the same (up 0.04%); one brain against four separate: down 0.02%, by a hair.	`results/realms/stack/STACK.md`

72.3 Layer 3: live external software

The kind sets 21 to 27 below ran on the engines before omni-v1 and are kept as their record; "clear of the noise" is that day's "proven" (an interval clear of zero). The live record of the engine that stands, omni-v26, is `results/OMNI_INDEX.md`.

Class	Statement	Where
P	omni-v18 on a real card, NVIDIA A100 SXM4 40 GB (Lambda run 40079645681, 24 October), one run of 10 paired repetitions, the card's own meter: every service gauge STEADY (work per energy	`results/gpu/run-20261024T091235Z/GPU_REPS.md`

Class	Statement	Where
S	Set 21 energy is a declared model, not a meter: up 1.8% with parked machines at idle power (power given).	same (energy table)

72.4 Layer 4: independent physical measurement

Class	Statement	Where
O	Omni-Compass changes successful work per measured joule on a GPU, measured by a meter Omni-Compass does not read or control. The bench is built with three receipts (governor, actuator, outcome), the three contrasts (observation, authority, total), and result labels by rule; it has run on rented cards with the card's own meter (layer 3), not yet with an independent meter.	`scripts/gpu_paired.sh`, `docs/GPU_PREREGISTRATION.md`
O	Production data-centre energy effect.	—
O	Whether the power limit is the right actuator for LLM serving. Published measurements (arXiv 2605.11999, H200) find memory-bound decode draws 137–300 W of 700 W, so no power cap binds; clock scaling is what saves energy there (arXiv 2501.08219, GreenLLM 2508.16449). The pinned bench workload is compute-bound, where the cap does bind: a result on it does not transfer to LLM decode.	external literature
O	Wall-plug (whole-machine) energy effect; CPU package and DRAM (RAPL) effect.	—
—	What the GPU bench will attribute: per write, joules and requests against native, and which rule decided it (engine, floor, gate, reflex, heat, speed lock).	`tools/gpu_reps.py`

72.5 Negative evidence, kept

Nothing here is deleted when a later result looks different.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Class	Statement	Where
P	The run of 2 October: p95 response time **up 58.5%, slower** (510 to 809 ms), mean up 48%, LOSS; label by rule ENERGY IMPROVEMENT WITH SERVICE TRADEOFF. Cause: governor wiring (busy bursts served below the card's own clock); corrected in amendments 6-7, not yet re-run on a card.	`results/gpu/run-20261002T082232Z/GPU_REPS.md`, `docs/GPU_PREREGISTRATION.md`
S	Two-wire GPU card, the profiles of amendment 7 (removed in amendment 8): service 5.3% more work per energy with the median 14.8% slower; batch p95 up 7.0% (raw −4.8% to +20.3%). The card controller before amendment 6 gave p95 up 32.9% and 37.1%.	`docs/GPU_PREREGISTRATION.md`, history in git
S	Six organisms, the same runs before round 6: time over the service line **up 0.19 to 0.27 pp in every cell, LOSS**; band first is not held anywhere.	`docs/HISTORY.md` (the grid's file since written again)
S	Round 6 law (HPA target held at the operator's own, machine release margin 0.6), 20 paired seeds per organism, before the grid rerun: work per energy up 0.086% to 0.201%, time over the line down 0.010 to 0.031 pp (ahead of native in all six), work unchanged within its interval, every knob handed back.	`docs/REALMS_PREREGISTRATION.md` (round 6)
L	Set 21: modelled energy 1.8% **power given** with every machine powered (the only honest energy row on kind).	`results/live/LIVE_REPS_21.md`
S	Realm harness round 1 (superseded, kept): all five organisms **LOSS** (whole tower down 0.1%). Its Omni layer did not follow the shipped controller (no contraction authority or SLO reflex, the stack law in place of the HPA, request traffic paused, a site budget under native draw).	`results/realms/round1/`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Class	Statement	Where
S	Realm harness round 2: the Physics / Robotics / Autonomous organism **LOSS** (down 1.9%, violations up 2.9 pp); the Compute organism's 2.5% more costs 2.9 pp more service violations; 68 single muscles LOSS or power given, mostly batch pacing and cooling setpoints under the live cooling law.	`results/realms/REALMS.md`
L	Set 22, equal work: no CPU saving once Omni's own CPU is counted (service down 7.6%, its controller 0.070 cores more, together down 0.9%, inside the noise); modelled energy unchanged (down 0.1%).	`results/live/LIVE_REPS_22.md`
L	Set 20: the "same work" reading was wrong; requests were up 35%.	`results/live/LIVE_REPS_20.md` addendum
L	Sets 1–2: machine savings **withdrawn** — a broken probe had blinded the latency sense.	`results/live/LIVE_REPS_PROBE_DEFECT.md`
L	Set 3 with a working probe: Omni kept all 6 machines; no significant difference except more waiting pods.	`docs/HISTORY.md`
L	Set 21: pending pod-minutes up 238% and pod starts up 37%, both inside the noise.	`results/live/LIVE_REPS_21.md`
S	GPU and batch: energy 1–2% **power given**, power and heat margins 1–4% short of tight packers (AKS/Karpenter, CAST AI, Spot).	`docs/HISTORY.md`
S	Machine round trips 1.1 → 1.7 per run (**power given**: a round trip is wear) in 6 of 8 seed-target combinations.	C12
S	Power-protect mode: backlog violations 2.5% → 6.7% (**LOSS**).	C12p
S	Park strategy on PlanetLab shapes: energy up 1.3% vs HPA+CA and up 33.6% vs Karpenter-lite (**power given**).	C17

All patents, copyrights and trademarks filed in the USA.

Class	Statement	Where
S	Typical response time about 20% slower than every platform in the web and four-cluster models (LOSS).	`docs/HISTORY.md`
S	GPU model: the engine without its guards breaks the p95 guardrail.	`results/gpu/sim/FINDINGS.md`
S	The compass-stroke GPU variant was tried and not adopted.	same
S	Right-sizing against VPA: p95 up 15% and memory (OOM) kills up 531% (LOSS).	`docs/history/BENCHMARK_REPORT.md`
—	Reported in the external master-build report (not reproducible from this repository): on fresh scenarios Karpenter+VPA sometimes used less modelled energy than Omni, while Omni had lower churn and fewer request-induced evictions. Kept here so it is not lost; to be re-run here before it is cited.	external

CHAPTER 73

The Claims Register

Every claim, its evidence status and the command that reproduces it. The modelled results (class S, our own models) use the synthetic stack model in `omnicompass/stack_sim.py` and the fleet harness (`fleet/`); they are not measurements of any production system, and a model is never offered as proof. This register is the record of those models from before omni-v1; the record of the engine that stands, omni-v26, on real software is `results/OMNI_INDEX.md`.

CHAPTER 74

Comparison with Existing Controllers

People who run these systems often see "autoscaling" everywhere and assume it all does the same thing. It does not. This page sets out, from public descriptions, what each system controls, and where Omni-Compass sits among them. The five systems named most often, nine open-source pieces read from their own repositories (license, kind, where each can run, its register row) and the formal distinction between one governor and a collection of tools: `docs/THE_SEAT.md`.

How to read it. Borg and Twine are private to Google and Meta; Turbonomic is closed commercial software. None of them can be run here, so they are compared by what their makers have published (papers, documentation, product pages), never by a run. A mark of "—" means the capability is not in the system's public description, not that it is impossible for it. The only fair measured comparison is on the customer's own system: their stack as it runs today against the same stack with Omni-Compass on top, in paired runs (`docs/INTEGRATION_MANUAL.md`, section 6).

74.1 What each system controls

System (public description)	Pods / replicas	Machines	GPU power	CPU clock / power	Moves watts between CPU and GPU	Site power budget	One decision across all of these
Kubernetes HPA	✓	—	—	—	—	—	—

System (public description)	Pods / replicas	Machines	GPU power	CPU clock / power	Moves watts between CPU and GPU	Site power budget	One decision across all of these
Omni-Compass	✓ (on top of HPA; or deciding)	✓ (park and wake)	✓	✓	✓ (conveyance law; simulated)	✓ (simulated)	✓

74.2 How each one decides

	Typical rule	Omni-Compass
Pods	add replicas when average CPU passes a target	the same autoscaler keeps working; Omni-Compass sets its target from the whole system's state and raises floors ahead of bursts
Machines	add when pods cannot be placed, remove when underused	park and wake machines by one law, and only when every sense is live, pods are not rising and nothing waits
GPU	vendor default: full power, or a fixed cap set by hand	a cap from the engine, bounded by a floor and released at once when the card is busy or response time slips
CPU	the kernel's governor picks a clock from recent load	a ceiling from the same engine, inside the nervous system's envelope
Power	a fixed plan leaving room for every device at peak; a breaker or capper reacts when the site goes over	one conserved budget: watts move from organs holding surplus to organs in need, never created, never over the budget
Safety	per tool	one OFF switch returns every organ to its recorded setting; watch mode first; service first

74.3 What is different, in plain words

1. **One brain instead of many separate reflexes.** Today each tool watches its own gauge: the pod autoscaler watches CPU, the node autoscaler watches pending pods, the GPU runs at its default, the power plan is fixed on paper. Nobody decides for the whole. Omni-Compass reads the whole system into one state and tells each tool the envelope it may act in. The tools keep doing their own jobs.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

2. **Power as a budget that moves.** Today a building keeps room for every device to hit its peak at once, so much of its power sits reserved and unused. Omni-Compass treats the building's watts as one conserved total and moves them to where the work is: from CPUs and quiet GPUs to busy GPUs, never over the limit (`docs/CONVEYANCE_LAW.md`).
3. **A proof, not a tuned dial.** The budget law is proved to conserve the budget and to converge, and those properties are checked on every build (`tests/test_conveyance.py`).
4. **Service guarded on every power move.** Power is only taken back while response time is inside the target, and given back at once when it is not.
5. **Reversible in one move.** Every setting is recorded before it is changed and restored by one switch.

74.4 What the numbers show today, and what kind they are

Against	Result	Kind
Kubernetes as it ships (its HPA and scheduler), omni-v25	the 95th percentile down 41% to 66% on the steady, wandering, all-four and fault tests: faster answers, GAIN in all three of our runs; the replicas it adds shown beside them as power given; the Kubernetes category of the Omni index GAIN 20.5%	measured on real Kubernetes (kind) on GitHub's machines, ten pairs a run, three runs, `results/live/V25_STEADY.md`, `V25_WANDERING.md`, `V25_ALL_FOUR.md`, `V25_FAULTS.md`, `results/OMNI_INDEX.md`
A GPU at its vendor default	1.3% to 5.1% more work per energy, the 95th percentile within 10% of native's	modelled card (MLPerf-calibrated), an earlier card controller, `results/gpu/sim/after`
Today's power practice (every GPU at one fixed cap that leaves room for every CPU at peak)	1.4% to 5.7% more work served, the backlog down 16% to 28%, never over the site budget	modelled, `results/hardware/NODE_EXCHANGE_*.json`
A reactive site capper alone	60-196 minutes over the site budget without Omni-Compass; 0 with it	modelled

Turbonomic, Borg and Twine cannot be measured here. Against a customer who runs one of them, the comparison is made on the customer's own system, with the same paired method.

Where a row above is wrong or out of date, correct it from the maker's own publication.

CHAPTER 75

The State of Play

How to read this receipt. Every judged row reads one of three words, decided by what its gauge is for and never by the plus or minus sign of its number. **GAIN**: the gauge moved toward its declared aim against native (more work done, a shorter wait, fewer misses or failures, or a resource cut). **STEADY**: native and Omni-Compass within 0.5% of each other (the mean of the three runs' changes under the 0.5% floor, or no change at all), or the knob is at its limit on native. **LOSS**: the gauge moved away from its aim (less work done, a longer wait, more misses or failures). A resource spent or held (energy, the power drawn and its peaks and swings, machines, memory, processor time, a bill, wear) that fell is a cut, a GAIN; one that rose is **power given**, what Omni-Compass put in to buy the work and the speed shown beside it, always shown and never called a loss; work bought with each unit of a resource (work per energy) that fell is power given too. So a minus can read GAIN (a response time cut) and a plus can read LOSS (failed requests up). A change of 0.5% or more, the mean of the three runs' changes, reads GAIN, LOSS or power given: **in all three of our runs** where A, B and C moved the same way with every interval clear of zero, otherwise **by the mean of our three runs**, with the count of runs beyond the noise beside it; **the runs disagree** names runs that moved 0.5% or more in opposite directions, a test unstable there; **shown, not judged** is a gauge declared shown only. The output follows the input: every reading is the result of the tune, the wiring and the load it names, and where a reading elsewhere differs the first presumption is the wiring (`DISCLOSURES.md`, section 4). The full key, letter by letter: `docs/HOW_TO_READ_THE_RESULTS.md`. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results. Preregistered means the rules were written down in our own repository before the runs; nothing was filed with any outside body.

Current facts only. Earlier states, failures and chronology are kept whole in `docs/HISTORY.md`. The release this page describes is identified by `RELEASE_MANIFEST.json` (commit, fingerprints of the engine,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

the C++ twins, the GPU protocol, the live evidence and the verification receipt), which `verify.py` checks against the files.

Rerun everything: `pip install -r requirements.txt && python verify.py` ends with `VERIFICATION: PASS`.

Where things stand, read from the result files. Written by `python3 tools/summary.py --fix` from the files it names; `verify.py` fails a push in which this block no longer matches them. Nothing in it is typed by hand. The live results run on the engines named in their own tables, and every one of them runs again on the newest engine.

- **The engine on this checkout:** omni-v26, fingerprint 75d3c22eed4473b9 (65 files).
- The muscles and the seven organisms on engine omni-v8 at the max (evidence class S, our own models; run 2026-10-17 15:39 UTC, commit 9819a903cba3, 1107 muscles; source: results/realms_v5/REALMS_V5.md):
  - every muscle alone, over its loads: STEADY 577, GAIN 530
  - the organisms under the normal load: the spine: GAIN (fewer misses), misses down 0.145 pp, energy STEADY, up 0.011% (under the 0.5% floor); Compute / AI / Cloud: GAIN (fewer misses), misses down 0.070 pp, energy STEADY, up 0.009% (under the 0.5% floor); Physics / Robotics / Autonomous: GAIN (fewer misses), misses down 0.121 pp, energy STEADY, up 0.010% (under the 0.5% floor); Energy / Facility / Industrial: GAIN (fewer misses), misses down 0.118 pp, energy the same; Distribution / Specialized: GAIN (fewer misses), misses down 0.067 pp, energy STEADY, up 0.002% (under the 0.5% floor); the four stacked: GAIN (fewer misses), misses down 0.092 pp, energy the same; the whole tower: GAIN (fewer misses), misses down 0.051 pp, energy the same
  - the organisms under the climb load: the spine: GAIN (fewer misses), misses down 0.632 pp, energy STEADY, up 0.039% (under the 0.5% floor); Compute / AI / Cloud: GAIN (fewer misses), misses down 0.390 pp, energy STEADY, up 0.046% (under the 0.5% floor); Physics / Robotics / Autonomous: GAIN (fewer misses), misses down 0.317 pp, energy STEADY, up 0.021% (under the 0.5% floor); Energy / Facility / Industrial: GAIN (fewer misses), misses down 0.217 pp, energy the same; Distribution / Specialized: GAIN (fewer misses), misses down 0.460 pp, energy STEADY, up 0.026% (under the 0.5% floor); the four stacked: GAIN (fewer misses), misses down 0.349 pp, energy the same; the whole tower: GAIN (fewer misses), misses down 0.094 pp, energy the same
  - the organisms under the line load: the spine: GAIN (fewer misses), misses down 0.371 pp, energy STEADY, up 0.038% (under the 0.5% floor); Compute / AI / Cloud: GAIN (fewer misses), misses down 0.205 pp, energy STEADY, up 0.045% (under the 0.5% floor); Physics / Robotics / Autonomous: GAIN (fewer misses), misses down 0.250 pp, energy STEADY, up 0.030% (under the 0.5% floor); Energy / Facility / Industrial: GAIN (fewer misses), misses down 0.117 pp, energy the same; Distribution / Specialized: GAIN (fewer misses), misses down 0.142 pp, energy STEADY, up 0.006% (under the 0.5% floor); the four stacked: GAIN (fewer misses), misses down 0.176 pp, energy the same; the whole tower: GAIN (fewer misses), misses down 0.051 pp, energy the same

- The grid (source: results/grid_v5/GRID.md, its signs put in words): Across the grid: modelled, 36 of 36 squares of 10 and 100 runs GAIN (fewer misses); the 18 single runs: 18 with fewer misses; work STEADY, the same (raw +0.000%); energy STEADY, up 0.000% to 0.065% (under the 0.5% floor); with the cluster inside, 54 squares: 18 single repetitions (no reading); of the 36 of 10 and 100 repetitions, by gauge: "organism time over the line (% of steps)" GAIN in 36, LOSS in 0, "time over the response line (% of samples)" GAIN in 36, LOSS in 0, "response time (ms), 95th percentile" GAIN in 26, LOSS in 2, "energy (Wh)" GAIN in 26, power given in 0, "energy, parked workers still on at idle power (Wh)" GAIN in 26, power given in 0, "organism energy (J)" GAIN in 0, power given in 22, "organism work per energy" GAIN in 0, power given in 22, "failed requests (%)" GAIN in 18, LOSS in 0, "response time (ms), 99th percentile" GAIN in 12, LOSS in 2, "HPA replicas, mean" GAIN in 4, power given in 5, "pods started" GAIN in 3, power given in 0; off the clock in 3; invalid in 0.
- **The four arms** (`results/TWO_BILLS.md`): **A**, the chip native, and **B**, the chip with Omni-Compass on native (omni-v23, three runs): B against A, the bill STEADY, under the floor (the three runs' mean 0.01%), the work done the runs disagree, work per dollar the runs disagree; **C**, the cloud native, and **D**, the cloud with Omni-Compass on native (omni-v18, 97 paired repetitions on Azure): D against C, the bill up 1.21%, inside the noise; Google and Amazon wired, not yet run.
- The Omni index (evidence class L, real software on real computers: the software end, not bare metal and not the chip; every measure judged across our three runs; the three-run tables of omni-v26, each named in its table): GAIN 20.0% on the software end's reading (work, speed and machines; energy shown, never scored where no meter read it), GAIN 96.5% on the service reading (work and speed alone); the reading declared on 4 October, the modelled energy scored too: GAIN 20.5%. Source: results/OMNI_INDEX.md.
  - Real messaging (Apache Kafka, GitHub): GAIN 221.1%
  - Real Kubernetes (GitHub): GAIN 22.2%
  - Real database (PostgreSQL behind PgBouncer, GitHub): power given 1.8%
  - Real cache (Redis, GitHub): power given 4.9%
  - Real database cache (MongoDB under YCSB, GitHub): power given 7.1%
  - Real database buffer pool (MySQL under sysbench, GitHub): power given 12.5%

On the engine that stands (omni-v26): 23 of 26 benchmarks so far. Every other row is that engine's own result, named in its Engine column, and runs again on the engine that stands (`scripts/reruns.txt`); results are never read across engines.

Benchmark	Engine	Its one number	Its word	Class
Every real test together: the Omni index	omni-v26	20.0%	GAIN AND LOSS	L

75.1 The engine that stands

omni-v26 (`OMNI_V26.json`, digest `75d3c22eed4473b9`, 65 files; `docs/OMNI_V26.md`), on main from 7 November: omni-v25 with one fault fixed in the Kubernetes governor: when a service's target stood below native's and pods waited, the decision returned native's target without starting the immune hand-back's hold, so the next decision with no pod waiting failed up again and a batch queue's normal waiting flipped the web service's target every one or two decisions; the decision now starts the hold itself when the waiting pods include those of a workload no autoscaler governs, and the fail-up is not taken again while it runs (`docs/LOSS_CAUSES_2026-11-06.md`; the model gate against omni-v25 identical on all 104 readings, no LOSS). Everything else it runs is omni-v25's (`docs/OMNI_V25.md`, on main from 3 to 7 November: the Kafka wire's producer started before the governor's thread) and omni-v24's (`docs/OMNI_V24.md`, on main from 1 to 3 November): omni-v23 with the heartbeat it ships with read from the place it runs in, on the founder's orders that the factory beat is the best beat the sweeps read and that it is found and then locked. With no beat set, the Kubernetes governor reads the cluster's nodes once at its start: on site (kind, the owner's own machines) it decides every 10 s; through a cloud (a node that names a public cloud's machine) every 60 s; a reading that fails keeps 60 s, and a beat set by hand always wins. The rule that picked the two beats was frozen before any reading was seen (`docs/PACE_PREREGISTRATION.md`, amendments 4 to 6): on site 10 s was the one beat no other dominated; through a cloud no beat kept the bill from rising, so 60 s stays and those rows are on the next version's list. 64 of its 65 files are omni-v23's bytes; the model gate against omni-v23 (`results/model_gate/V24_VS_V23.md`, class S): no LOSS against omni-v23; eleven of its twelve models identical on every gauge and seed; on site, at its 10 s against omni-v23's 60 s, the minutes over the response line down 60.7%, the 95th percentile down 8.2% and the autoscaler's shortfall down 5.1% (fewer and faster, GAIN), the machines the same, the reads of the cluster and its own processor power given. Every benchmark runs again on it from 01:30 UTC on 2 November (`scripts/reruns.txt`); the omni-v23 runs started before run to their end as omni-v23's record.

omni-v23 (`OMNI_V23.json`, digest `c96ea4105d8747db`, 65 files; `docs/OMNI_V23.md`), on main from 31 October to 1 November: omni-v22 with one guard in the Kubernetes governor's pod muscle of its own, on the founder's order of that day that Omni direct keeps every muscle Omni-Compass cannot be. A write of a workload's own scale that the cluster refuses is recorded and the decision goes on; at three refusals in a row the knob goes back to native's own pod autoscaler, made from the operator's target and range recorded on the workload, and the muscle leaves the workload to it, so the organism never runs with a knob nobody moves. 64 of its 65 files are omni-v22's bytes; the model gate against omni-v22 (`results/model_gate/V23_VS_V22.md`, class S) read identical on every gauge of every model, no LOSS. Every benchmark runs again on it from 20:00 UTC on 31 October (`scripts/reruns.txt`); the omni-v22 runs started before run to their end as omni-v22's record.

omni-v22 (`OMNI_V22.json`, digest `0e23a0bc561b900a`, 65 files; `docs/OMNI_V22.md`), on main from 30 to 31 October: the five data stores' wires brought to the max. What a wire's own rule asks goes through unclamped, up to the operator's cover and never below native; memory is spent only where the store's own account of a miss (MySQL's performance schema timer on the data files' reads, WiredTiger's page-read

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

time for the application's threads, the Redis application's own split) says the misses are at least the one key's floor of the service's time, and only while the host keeps its 5% cushion; a hand-back never goes below the working set's floor; Kafka's group has a twin of its arrivals and a reflex; PostgreSQL's pool is never taken below the pooler's own setting (`tools/store_brain.py`, the five `tools/run_*.py` wires, `tools/knob_verdict.py`, all in the fingerprint). The model gate against omni-v21 (class S) read no LOSS at the counted setting on every store wire; the Kubernetes governor's models read omni-v21's own numbers on every gauge (the one governor change, the hand-back tried five times against a transient failure of the cluster's API, moves no decision). Every benchmark runs again on it from the moment it reached main (`scripts/reruns.txt`, released by the conductor), the five stores first. omni-v21 (`docs/OMNI_V21.md`, the immune system knows itself, knob by knob) stood from the evening of 25 October to 30 October; its tables stand as its own record until omni-v22's three runs of each benchmark land. The block above is written from the result files on every push: each row names the engine its table ran on, and every three-run table of omni-v21 is rebuilt byte for byte from its archived runs by `tools/reproduce.py` (all 31 on 27 October). Each earlier engine is on its own page (`docs/OMNI_V<n>.md`); the chronology this page carried until 27 October is whole in `docs/history/STATE_OF_PLAY_2026-10-27.md`.

75.2 The whole system, every layer composed

`results/WHOLE_SYSTEM.md` (built by `tools/whole_system.py`) composes the layers from the tables that stand: each layer's ratio toward its gauge's aim, $R\ell(g) = o\ell/n\ell$ or $n\ell/o\ell$, measured with the layer under it as native runs it, composed by the product law $R(g) = \prod_\ell R\ell(g)$, every run's paired interval carried by the delta method, the three runs pooled by inverse variance. It is class S over class P and L tables and across engines, and says so; the stacked run, Omni-Compass at every layer at once on one machine (the GPU's stacks mode, `lambda-gpu.yml`), is the measurement that replaces it. The numbers stand on that page, never copied here.

The people, counted: the oversight line (`results/OVERSIGHT.md`, written by `tools/oversight.py` from the tables). The Omni index counts work, speed and machines, never a person; the receipts count the people too, in both arms. Across the 37 real Kubernetes tests of omni-v26, the minutes an on-call page would be open (the 3 a.m. call) went down 11.0%, fewer in 13 tests and to none in 3, and down in each of our three runs beyond the noise (GAIN in all three of our runs), while the governor turned the knobs itself (227; 207; 226 settings an hour in runs A; B; C, no person touching either arm). Counted as pages from the same runs' raw files by the rule written before the count, the pages a person would have been sent went down 12.2% (GAIN by the mean of our three runs, beyond the noise in 2 of 3; `results/OVERSIGHT_PAGES.md`): fewer pages, each open about as long. In the bill it is the people line, $b = s(\text{people}) \cdot b(\text{people})$ at the owner's own share: at the founder's example of 7%, down 0.8% of the whole bill. It is not added to the index (a share of a bill and a reading of work and speed do not add), and it removes no person: a person keeps the switch.

75.3 Open

Each with its receipt, run by run, in `docs/RUN_LEDGER.md`.

1. **The card.** omni-v21 on an A100, three runs each (`results/gpu/V21_A100_SAVE_ABC.md`, `V21_A100_CAP_ABC.md`, `V21_A100_CAP_FULL_ABC.md`). At the factory dial (the max) STEADY with no write: native already runs both knobs at their top. The tune-down (dial save): work per energy GAIN by the mean of our three runs (up 0.75%, beyond the noise in 1 of 3), every service gauge STEADY. The cap at 70%: the mean response time LOSS by the mean (beyond the noise in 0 of 3, run A alone). The tune-down as the card's factory dial goes through the model gate as the next version on the founder's word; the cap's rows are on the next version's list. The stacked box (three A10s, `results/gpu/V21_STACKS_A10_ABC.md`): at 1 and 10 copies, complete in all three runs, the card STEADY in every organism; 100 copies one repetition a run, shown, not judged. Where the chip proof stands, what the card's own files say about the mechanism, and what it still needs, step by step with its cost: `docs/THE_CHIPS.md`.
2. **The three-arm showing on omni-v21** landed (`results/orchestrator/V21_THREE_ARMS_ABC.md`, runs 40474220398, 40474223636, 40474227699): Omni-Compass on top of native against native, work GAIN in all three of our runs (up 8.5%), the 95th percentile GAIN in all three (down 13.0%); the answer at the top of the README reads it.
3. **Azure**: the omni-v18 set of 100 paired repetitions finished 29 October (97 passed, 3 failed) as omni-v18's record; the omni-v21 steady set runs (16 of 100 by 30 October, 16:27 UTC: 14 passed, 2 failed, about 68 minutes a repetition); the omni-v22 sets queue behind it, one at a time, each behind Azure's own $0 check (`scripts/azure_queue.txt`; `docs/THE_CHIPS.md` section 6).
4. **Google and Amazon**: wired as Azure's sets are and switched off; GitHub's own check of 27 October (`cloud-check`) reads their four keys absent from this repository's secrets (`GCP_CREDENTIALS`, `GCP_PROJECT`, `AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`; `docs/GOOGLE_SETUP.md` section 4, `docs/AMAZON_SETUP.md` sections 1a to 3).
5. **The CPU package** (`cpu-power`): needs a bare-metal machine; GitHub's are virtual, with no frequency governor and no energy meter, and the workflow fails rather than hide it.
6. **The three rows still on omni-v3** in the block above, until their omni-v21 runs land.
7. **Every LOSS row on omni-v21**, each with its cause in `docs/LOSS_LEDGER.md`: the next version's work, through the model gate first.
8. **Omni-Compass 1.0**: when the founder declares the engine final, the engine that stands then is published as 1.0 and the older fingerprints go to `docs/history` as the road to it.

PART EIGHT

Value, License and History

What a receipt is worth, how the license is priced against it, how the code is sealed, and how Omni-Compass came to be.

CHAPTER 76

Where the Value Comes From

76.1 The problem we are attacking

Computing has run into a wall that is not made of silicon. Data centers cannot get the power they need, cannot get it fast enough, and are running out of room to put more machines. AI made it harder: every new model needs more chips, and every chip needs more electricity and more cooling. The answers on the table are expensive and slow: new chips that do more work per watt (a new generation, new hardware to buy), new power plants and power contracts (billions, and years), and point fixes at a single layer (an AI serving trick, a scheduler, a power cap on one chip).

We attack it from the other side. Every system already running wastes room it paid for:

- GPUs boost to the top of their clock range and are knocked back by their own power limiter many times a second;
- Kubernetes keeps replicas and machines sized for the worst minute of the day;

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- cooling runs colder than the heat requires; batteries hold more reserve than the hour needs.

That room is paid for in energy, in machines and in floor space, and it produces nothing.

Why the room is there is worth a paragraph, because it decides what can be done about it. Each layer of a stack is sized by someone who cannot see the others. The autoscaler's author does not know what the power cap will do; the cooling engineer sizes for the hottest hour of the year; the database operator sets a buffer pool for the largest table and leaves it there; each of them, sensibly, leaves a margin against the layer next door, and the margins add up. None of these people is wrong. The waste is not a mistake anyone made; it is the price of layers that cannot talk to each other, and it is why a fix at one layer, however good, moves the margin rather than removing it. The benchmarks in this manual are each a measurement of one such margin on real software: the connections a pooler holds open that no client is using, the memory a cache keeps for data it will not be asked for, the machines a cluster keeps in service for a minute that has passed. Each is small on its own and each is paid for every hour of the year.

The attack, then, is not another autoscaler or another cache. It is a governor that reads every layer's own gauge, keeps each layer in the middle of its own band, and gives the margin back where the layer's own controller shows it is not needed, with the layer's own controller still underneath and the layer's own setting restored when the governor is gone. That is a different kind of thing from a point fix, and it is why it stacks on top of every point fix a data center has already made rather than competing with any of them.

76.2 What Omni-Compass is, in one paragraph

Omni-Compass is software that sits **on top of** the controllers a system already has (the GPU's firmware, the Kubernetes autoscaler, the building's thermostats) and governs every layer under one law: a bounded push and pull that keeps each service in the middle of its band instead of far below its limit. It never replaces the native controller, never asks for more than the native settings allow, hands every knob back the moment it is switched off or loses a sense, and refuses any step that measures a LOSS of more than 2% on anything. No new hardware. It stacks on top of every other fix a data center makes.

76.3 The benefit: more work from what is already paid for

The room that was spent on nothing becomes one of two things, and a company chooses which:

- **More work for the same cost:** the same machines and the same watts carry more work; or
- **The same work for less:** fewer machines in service, fewer watts, a smaller bill.

They are the same gain read from two sides (3.4). The health side comes with it: faster answers, faster recovery from failures, nothing waiting, every knob returned, no human babysitting the stack.

The results to date (chapter 60) show both readings on real software, and show that which one a stack gets is decided by the stack, not by Omni-Compass. On the real Kubernetes cluster the gain is taken as **more work, faster**: the cluster carries more requests inside its response line on the same machines. On the data stores the knob is a resource an operator sizes (the pooler's connections, the buffer pool, the storage engine's cache, the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

consumers, the memory ceiling), and each store's own table says which way it went: a resource cut for the same work (GAIN), or a resource spent for more work or speed (power given, shown beside the gain it bought), each notch proved on the stack first and the resource handed back at the end of every run. The combined index is section 60.11's, written from its record, every LOSS counted at full weight. An operator should expect the same honesty from their own paired run: the receipts will say which side of the gain their stack took, and whether the compass's own cost (its CPU, its reads) ate into it.

76.4 How to read the benefit: the arithmetic

Every comparison is paired: the same system, the same work, the same moments, native alone against native with Omni-Compass on top. Let

- *W* be the work served (requests answered, tokens generated), held equal in both arms;
- *C* be a resource it used: machine-hours, CPU core-hours, or joules.

Productivity is work per resource, $P = W / C$. With the work held equal, the gain from Omni-Compass on top is

$G = P[omni] / P[native] - 1 = C[native] / C[omni] - 1$.

A gain *G* means the same resources can carry *G* more work. Read from the other side, the same work needs only

$C[omni] / C[native] = 1 / (1 + G)$

of the resources, a saving of $S = G / (1 + G)$. So **a third more work (G = 33%) is a quarter off the bill (S = 25%)**; 20% more work is 16.7% off; 50% more work is a third off. Both columns are the same measurement.

Three rules for reading any receipt:

1. **The work must be equal.** Every receipt states that the load was fixed-rate (open loop): the same requests at the same moments in every arm. Without that, a lower resource count could just mean less work was done.
2. **Nothing may read LOSS.** Beside every gain the receipt prints response times, failures, waiting and the controller's own CPU, each with its 95% interval. Our one rule (`DISCLOSURES.md`, section 3): no LOSS of more than 2% on any measure, and only where energy or the bill is saved. A GAIN paid for with a LOSS of service is not a GAIN.
3. **Know the class and the comparator.** A machine-hour gain on kind (where idle machines stay powered and native has no node autoscaler) is not yet a bill; a modelled energy line is not a meter. Chapter 58 lists the classes; Chapter 60 says, for every result, what it is measured against.

A worked example, from the newest tables (written from the benefit sheet's record by `python3 tools/results_chapter.py`). In the all-four Kubernetes test (`results/live/V26_ALL_FOUR.md`, omni-v26) the same machines answered 31% to 50% more requests inside the response line: *G* is 0.31 to 0.50, so the same work would need 1/1.31 to 1/1.50 of the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

machines, a saving $S = G / (1 + G)$ of 23.7% to 33.3%, had the fleet been free to shrink; on kind it was not, which is why the table reports the work and not a bill. In the database test (`results/live/V26_PGBENCH.md`, omni-v26) the pooler held 18% to 34% more connections open (power given), so no saving of connections is drawn from it on this engine; the table reports what it bought with them. Which of the two a stack takes, more work or fewer machines, is decided by the stack, and each table reports what happened.

76.5 Where the evidence stands today, read honestly

Every number below is from a three-run table, each row naming the engine its table ran on; the evidence class of each is in the table it points to. The engine that stands is **omni-v26** (`OMNI_V26.json`, digest `75d3c22eed4473b9`, 65 files; `docs/OMNI_V26.md`, on main since 7 November): omni-v25 with one fault fixed in the Kubernetes governor: when a service's target stood below native's and pods waited, the decision returned native's target without starting the immune hand-back's hold, so the next decision with no pod waiting failed up again and a batch queue's normal waiting flipped the web service's target every one or two decisions; the decision now starts the hold itself when the waiting pods include those of a workload no autoscaler governs, and the fail-up is not taken again while it runs (`docs/LOSS_CAUSES_2026-11-06.md`; the model gate against omni-v25 identical on all 104 readings, no LOSS); every table below is an earlier engine's own record, named in its row, until omni-v26's three runs of each benchmark land. Before it: omni-v25 (`docs/OMNI_V25.md`, 3 to 7 November), the Kafka wire's producer started before the governor's thread; omni-v24 (`docs/OMNI_V24.md`, 1 to 3 November), the factory beat for its place, a decision every 10 s on site and every 60 s through a cloud, read from the cluster's own nodes at its start; omni-v23 (`docs/OMNI_V23.md`, 31 October to 1 November), a knob whose own-scale writes the cluster refuses handed back to native's own autoscaler; omni-v22 (`docs/OMNI_V22.md`, 30 to 31 October), the five data stores' wires at the max, each spend gated on the store's own account of what a miss costs and on the host's room, never below native (`tools/store_brain.py`); omni-v21 (`docs/OMNI_V21.md`, 25 to 30 October), the immune system knowing itself, knob by knob (a knob redlining past its line that Omni-Compass's own pushing cannot bring back goes to native where native's twin reads it lower, and stays with Omni-Compass where native is not stronger). What each earlier version changed is in section 76.6 and on its own page (`docs/OMNI_V<n>.md`). Every benchmark runs again on the engine that stands; a row still on an older engine names it and stands as that engine's record until its three runs on the engine that stands land. Results are never read across engines.

The table is written from the benefit sheet (`docs/BENEFIT_SHEET.md`, `tools/benefit_sheet.py`) on every push, so this book quotes no number its tables have not given. Every table it names is rebuilt byte for byte from its archived runs by `tools/reproduce.py`, and every LOSS row is named with its cause in `docs/LOSS_LEDGER.md`. The questions a referee is entitled to ask of a row (whose load, which native, which window, what was spent to buy what) are answered in the table it points to.

What (engine, three runs each)	Benefit ?	How much	Every change judged across our three runs, in words	Table
The big organisms with the real cluster inside, 1,000 copies on Azure (omni-v3)	**GAIN**	155% GAIN	p95 cut 95% to 98% (GAIN); p99 cut 97% to 98% (GAIN)	`results/live/V3_BIG_ORGANISM.md`
The 945 modelled muscles as one tower, every muscle written at once (omni-v3)	**GAIN**	0.3% GAIN	work per energy up 0.3% (GAIN)	`results/realms/REALMS.md`

What is not in the table yet, and why, is in `docs/RUN_LEDGER.md`: the card's rentals and what came back from each, the clouds (Azure's bill at the tune-down; Google and Amazon wired and not yet run) and the CPU package, which needs a bare-metal machine. The bill becomes a claim, not a direction, when two tests land: the bill on a real cloud with a fleet big enough to show one machine, and the real card's own meter. We publish each of them as it comes, whatever it says.

76.6 One law, versioned; and what came before it

The engine in every result of this manual is **the compass law with the verdict** (chapter 30 and section 1.2), versioned and fingerprinted at every change: frozen as Omni v1 on 5 October 2026; grown to the 945-muscle catalog as v2; given the slack gate on speed knobs as v3; redesigned as **v5** (12 and 13 October) with the max as its default brain on the 1,107-muscle catalog, every muscle its own card, the living body and the lease's walk back (v4 was the written plan of that redesign, `docs/OMNI_V4_PLAN.md`, never fingerprinted); and given the shared-host capacity repair of the Kubernetes controller as **v6** (15 October); and given conveyance bounded by each namespace's quota, the verdict in the reports' words, every rule in seconds and the cloud's one flag as **v7** (16 October), tried in the model gate and in live trials first; given, as **v8** (17 October), the one wire omni-v7's CityLearn table showed was ours to fix: a battery that is also its building's reserve through an outage stays native; given, as **v9** (17 October), the battery wire reading the coming hour; given, as **v10** (18 October), the battery wire's glide at the speed that cuts the bill most with no LOSS, each proven on CityLearn and in the model gate before it was pushed; and given, as **v11** (18 October), by the founder's order that every fault found be fixed, the Kubernetes governor's hold on a reading with no machine in service, proven in a unit test that reproduces the fault and in the model gate; then, each the next version through the model gate, a raise the cluster refuses held and the swarm's reflex at once (**v12**), the limits handed back on a shared host at its top (**v13**), a knob that leaves any muscle native (**v14**), the power cap's request through the line's own clear time and every wire in the fingerprint (**v15**), every clock of the governor in seconds (**v16**), the heartbeat a dial with the factory's 60 s (**v17**), Omni direct taken into the engine (**v18**), a pod muscle of its own (**v19**), the five data stores' wires fixed at their causes (**v20**), the immune system knowing itself, knob by knob (**v21**), the data stores' wires at the max (**v22**), a knob whose own writes are refused handed back to native's controller (**v23**), and, as **v24**, the engine that stands since 1 November, the factory beat for its place, 10 s on site and 60 s

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

through a cloud (`docs/OMNI_V1.md`, `OMNI_V2.md`, `OMNI_V3.md`, `OMNI_V5.md` to `OMNI_V24.md`). From v11 on, a version's bookkeeping lands in one command (`tools/land_engine.py`), and the check it adds to `verify.py` refuses a push in which any place still names an older engine as the one that stands. Earlier engines, among them an allocation law that gave back about a third of the machines at the cost of response time and a compass law without the verdict, produced the numbered sets kept in `docs/history/`; their results are history, labelled as the engine that produced them, and are never read beside a later engine's. A buyer does not choose between modes: there is one law, and every table names the version of it that produced the table. When the founder declares the engine final, the engine that stands then is published as Omni-Compass 1.0, with the older fingerprints kept as the road to it, never as a second product.

"Versioned" has a precise meaning here. The engine is a fixed set of files (63 on v21), and `OMNI_V21.json` holds one SHA-256 for each of them and one digest over all of them; `OMNI_V20.json` back to `OMNI_V5.json`, `OMNI_V3.json`, `OMNI_V2.json` and `OMNI_V1.json` do the same for the earlier sets. `python3 tools/omni_version.py` hashes the files in a checkout and prints which fingerprint they match (for this edition, `omni-v26 (digest 75d3c22eed4473b9, 65 files)`), or, when they match none, which files differ from the nearest; with `--commit <sha>` it asks the same of any pushed commit, which is how every three-run table checks that its runs A, B and C were on the same engine before it combines them, and refuses if they were not. The versions differ in exactly the ways their records name, and a reader can check that from the fingerprints rather than from this sentence.

The rule that any change makes the next version is also the rule that keeps the results honest. A gain or a guard changed after a result is in would make that result unrepeatable on the engine that now stands, so the change moves the version, every result is run again on the new version, and the old tables keep their version in their name and move to history. The founder's standing order is that the engine is never changed without being told first; since 15 October every change is also tried in our own models against the engine that stands before any real run (`tools/model_gate.py`). This manual records no change made otherwise.

76.7 The output follows the input

Every number Omni-Compass produces is the result of three inputs, and a reader who changes any one of them has changed the result: **the tune** (the factory tune as shipped, or the dial turned down, or a card changed), **the wiring** (which muscles are wired in and which are watched, what each wire reads and writes, how fresh each feed is) and **the load** (the work offered, its shape and its line). The published receipts are the record of one setting of all three, and every receipt names it: the engine's fingerprint, the harness, the load and the window. The same engine wired onto another stack, or tuned to another purpose, gives another result, and that result is its own.

A team that wants a different outcome sets the inputs for it and reads its own receipts against native: the most work at any spend (the max, the default, in a cloud as on site since 31 October); the same work as native for a smaller bill (the tune-down, a tune anyone may set); a muscle held at a limit of the team's own choosing (its card, or its cover); a knob left native (watched, never written). Each of those is a legitimate setting of the inputs, and each has its own result. What no reader may do is read one tune's receipt as another's, or read a

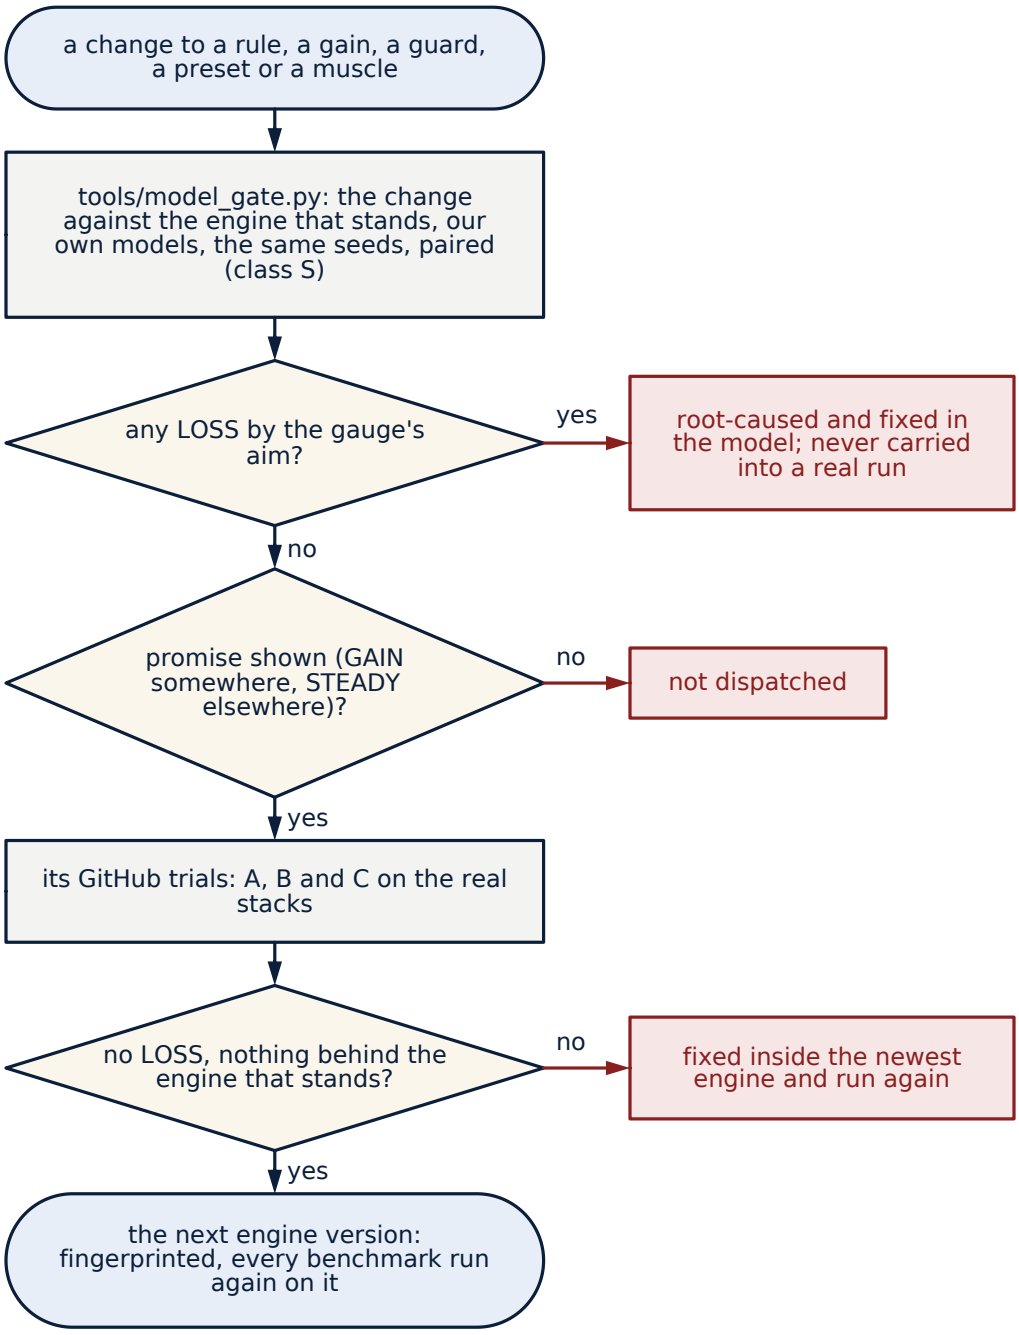

Figure 66. Flowchart: the model gate before any engine change runs for real. A change to a rule, a gain, a guard, a preset or a muscle runs first in our own models against the engine that stands, on the same seeds, paired (class S); a LOSS is root-caused and fixed in the model and never carried into a real run; a change that shows promise goes to its GitHub trials, and only one that reads no LOSS and nothing behind the engine that stands becomes the next fingerprinted version, on which every benchmark runs again.

receipt without its inputs. The factory tune is the one setting whose receipts this book publishes (the Declaration of the factory tune, `DISCLOSURES.md`, section 3); the dial and the cards are the inputs a

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

licensee may change, and a changed tune's results are its own (section 76.6). Where a result read elsewhere differs from the published one, the first presumption is an input: the wiring, the settings or the reading (`DISCLOSURES.md`, section 4).

76.8 Healthy production, how a configuration is chosen, the whole-workload benefit, and the scope of the validation

The founder's master specification of 24 October 2026, late night, is written once in `docs/FACTORY_PROFILE.md`; this section carries what the owner must hold of it, in its words.

What Omni-Compass consists of. A **governing engine** (the executable mathematical rules that turn observations and internal state into governing decisions), its **muscle adapters**, a **complete configuration profile** and a **validation harness** (the machinery that supplies workloads, executes comparisons, checks requirements and records results). The **factory profile** is the complete, versioned set of Omni-Compass default settings shipped together: the governing rules, gains, margins, the decision interval and every other default. A **candidate profile** is a proposed combination of settings under evaluation; the **active profile** is the settings actually governing the current run; a **custom profile** is an identifiable configuration that differs from the released factory profile. The released factory profile is omni-v26's (`OMNI_V26.json`): the governor's full decision every 10 s on site and every 60 s through a cloud, read from the cluster's own nodes at its start (a beat set by hand always kept), the fast checks every 5 s, every muscle on the card found for it (`realms/muscle_cards_v5.csv`) and on the engine's own setting otherwise; every result on the engine that stands runs on it, and every earlier result on its own engine's profile. The physiological words of this book (muscle, organism, nervous system, defensive system, health) are engineering analogies, each pointing to concrete code, signals, actuators and checks (`docs/FACTORY_PROFILE.md`, section 2).

A fixed tune supervising a changing system. Let x be the supervised system's state, z the supervisor's internal state, y its observations, θ the complete configuration profile and Δ the full governing decision interval. The public interval choices on the bench are $\Delta \in \{10, 15, 20, 30, 60, 90, 120\}$ s (the controller itself takes any value from 5 to 120 s, `--interval`). At decision k, with $t_{k+1} = t_k + \Delta$, the general contract is:

Step	Equation	What it is
observe	$y(k) = h(x(t_k)) + \varepsilon(k)$	the observation, with its sensing delay and noise ε
decide	$(u[req](k), z(k+1)) = G[\theta](z(k), y(k), A(k))$	the requested settings, inside the governing authority A(k)
Step	**Equation**	**What it is**
constrain	$u[cmd](k) = \Pi[C](u[req](k))$	the constraints C(k): every muscle's own limits, the cover, never below native at the max
Step	**Equation**	**What it is**

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Step	Equation	What it is
land	`u[ack](k) = R(u[cmd](k))`	the setting that actually landed, read back by the adapter
move	$x(t_{k+1}) = \Phi(x(t_k),$ `u[ack](k), w(k))`	the system moves with the command that landed, under the workload and disturbances w

G[θ] is the governing engine at profile θ. The system evolves with the command that actually landed, so the requested, the commanded and the acknowledged settings are kept distinct and each is logged (the audit; a refused write is held, omni-v12). After release θ(k + 1) = θ(k) = θ[factory] for every k, while x, z and u go on changing: one fixed factory tune governs a changing workload. "One setting" means one complete profile, θ = (the rules, the gains, the margins and cushions, Δ, the dial, every muscle's card, …), more than a choice of heartbeat, and its settings are evaluated jointly, because changing one mechanism can move others.

Healthy production: the two objectives. Health is the explicit operating requirements: correctness, service limits, resource bounds and every applicable hardware limit. With P(θ) the useful output (work done inside the line), C(θ) the whole-workload cost inside the declared boundary, $H_j(\theta)$ each health reading and L_j its limit, the two objectives are kept explicit, and each reported result names its objective and its exact profile:

maximise E[P(θ)] subject to $H_j(\theta) \le L_j$ for every health requirement j

(the most healthy production the system can deliver: the max, the default brain), or

minimise E[C(θ)⁄P(θ)] subject to the same requirements

(what that completed production costs: the tune-down, `dial save`, a tune anyone may set; the clouds ran it until 31 October, when the founder struck that rule and every cloud runs the max, the bill judged beside the work).

How a configuration is chosen. The factory baseline is established in eight steps: (1) verify the mechanisms: observations, units, authority, actuation, read-back, limits and recovery; (2) exercise the six governing intervals and the relevant knob combinations; (3) tune on development workloads, examining the interactions between muscles; (4) validate the selected profile on fresh workloads, bursts, sustained demand and the declared failure conditions included; (5) record every adverse result and resolve whether the candidate meets the release requirements; (6) freeze the complete factory profile, its engine identity and its validation receipts; (7) verify every corresponding implementation and adapter, the C++ harness included; (8) release that identified package as the factory baseline. The result is called **the best validated factory profile for the declared operating conditions**, which gives "optimal" an assessable meaning. Today the repository is at steps 1 and 2 for the next profile (the heartbeat sweep and the beat ladder, `results/model_gate/HEARTBEAT_SWEEP.md`; the newest ladder, on the corrected model, `results/model_gate/V23_LADDER_CORRECTED.md`, class S, from which omni-v24's beat for each place was picked by a rule frozen before the reading); steps 3 to 8 come after the founder confirms the mechanisms, and no profile is locked as the baseline before them. Every engine version already passes the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

model gate and the three-run rule before its results stand. The tune rule of section 12.4 is how a released tune is read against the tunes tried so far; it is not the eight steps.

The whole-workload benefit: the bill. For each deployment route r (on-site hardware; through the cloud), the costs inside the declared boundary are added, each counted once, for each arm a (native, Omni-Compass on native, Omni-Compass direct):

$C(r, a) = \Sigma_k\, c(r, a, k)$, $S(r, a) = (C(r, \text{native}) - C(r, a)) / C(r, \text{native})$,

for a positive native cost and a valid, matched workload comparison. The two headline views are the total native cost, the total Omni-Compass cost and the percentage saved, on site and through the cloud. A component's percentage is a supporting measurement; the bill's percentage comes from adding the actual costs. A missing price or an incomplete workload stays visibly unresolved: today only the cloud's compute is metered in money (Azure, machine-hours at the list price, `results/live/AKS_BILL.md`); energy, machines, storage, network and operation carry no recorded price, so neither route's total is resolved yet, and the live benchmark engine shows each component as unresolved beside its measured change. The whole-workload index of section 60.6 is the composition's one number over its gauges, not a price.

The scope of the validation. Every result identifies the engine version, the configuration, the hardware or model, the workload and the measurement boundary that produced it, and says nothing beyond them. The Python, the C++ and the browser port share one behavioural contract: the same profile values, meanings and units; the same governing intervals and time-based rules; the same authority and constraint decisions; the same handling of stale observations, refused commands and recovery; exact agreement for discrete decisions, with tolerances fixed in advance where floating-point arithmetic needs them (`tools/seal.py`, `results/SEAL.json`, `docs/engine/check_live_engine.py`). A release record identifies the engine version and its fingerprint, the profile, the implementations' parity receipts and the validation receipts: a matching fingerprint establishes identity; the validation receipts establish what that identified implementation demonstrated, on the systems, loads and boundaries they name. The live benchmark engine's adjustments are variations of the mechanism on its stated backend (class S on the page's own model); an adjustment becomes a factory configuration only after validation and a new release declaration.

CHAPTER 77

The Economics of a Receipt

Run the stack native and print the receipt. Run the same stack with Omni-Compass and print the receipt. The difference is the gain, read from either side: more work for the same energy, or the same work for less energy and fewer machines.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The license fee is set against the measured gain on the customer's own receipt. On a stack that costs one hundred, a measured gain of ten is worth ten; the fee is a share of that ten, and the customer keeps the rest. Percentages from different parts of a stack are not added into one bill: the invoice is one gain, measured once.

The value a customer sees comes in three forms, each on its own line of the receipt:

1. **Work per energy** - more finished work per kilowatt-hour.
2. **Capacity** - the same work with fewer machines in service (a kind of benefit, not a result: on omni-v25 the whole organism's composition reads its machines 77.7% more, power given, `results/WHOLE_SYSTEM.md`); it becomes a cost reduction when the released machines are returned to the cloud or switched off by the platform around Omni-Compass.
3. **Service** - faster responses and fewer breaches at the same load.

The babysitting tax - the people and tools kept on the clock to set caps, answer pages and turn knobs back after a run or a crash - is the cost Omni-Compass removes by holding the knobs and returning them itself.

The receipt's arithmetic, and the one number. With the work held equal, a gain G in productivity is the same measurement as a saving S = G / (1 + G) in resources: a third more work is a quarter off the bill (manual, section 76.4). Across every real stack the one number is the Omni index (`results/OMNI_INDEX.md`): each test's work, speed, machines and energy as ratios, combined by geometric means so that a gain and an equal loss cancel exactly, each real category weighed the same, and only rows the same in all three of our runs counted. The index is honest in both directions by construction. As this edition is written it reads +30.2%: real Kubernetes +25.5%, the database +14.2%, messaging +166.9%, and the cache −24.9%, the last negative because the memory the governor holds for a wide working set is the resource it trades and reads power given by rule, even as the cache's work and hit rate read GAIN. A buyer reads the category that matches their stack, and reads its losses in the same table as its gains.

What a receipt is not. A receipt is not a forecast. It is the measured difference between two arms on one system at one time, with its interval. The only number that applies to a customer's system is the one their own paired runs produce, and the method of those runs is the manual's Chapter 57, the same method every table in this book was made with.

CHAPTER 78

Due Diligence

Answers reference the Claims Register (C-numbers) and the Technical Manual.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

78.1 Engineering

Does the mathematics hold? Equations (1) to (8), Propositions 1 to 3 and their proofs are in Manual Chapters 2 and 3. The 500/500 CONVEY/CERT result is a property of the controller (Proposition 3), shown by counterfactuals: the controller aimed at the wrong basin also scores 500/500. **Is Python the same as C++?** Yes (C1, C2). The verifier also builds a deliberately mutated C++ governor and checks that the parity test rejects it. **Can every number be reproduced?** `python verify.py` rebuilds the C++, reruns parity, reruns the 100,000,000-decision soak and compares it with the recorded result, replays held-out scenarios and checks the pre-registered SHA-256 hashes (program fingerprints are additionally checked when the Python version matches the recorded one).

78.2 Operations

Against what we run today? On real software, against the native controller as its project ships it: Kubernetes' own pod autoscaler and scheduler on real clusters, and the data stores as their vendors ship them, paired, three runs each (`results/OMNI_INDEX.md`, class L). In the models (class S, C8 to C12), against a documented-behaviour reference model of Kubernetes autoscaling (HPA tolerance 0.1, 300 s scale-down stabilization, HPA targets 0.5 to 0.8; simplified Cluster Autoscaler with 10-minute unneeded time, 0.5 utilization threshold, 10-minute delay after scale-up): C8 to C12, including where Omni-Compass read LOSS. The reference model is not the upstream controllers (C12b); running the upstream controllers against the same scenarios is the next baseline step. **On real traffic?** Not yet: no production traffic. The live results run real software on GitHub's machines with generated load and a public day of demand replayed (the Google cluster trace of 2011, `results/live/V25_TRACE_GOOGLE2011.md`); the models use a synthetic stack model. The pilot protocol is the next evidence step (C14). **What happens when it is wrong?** Observe mode changes nothing (C6). The reset returns control to the native managers at the next interval (omni_kill arm). The shield blocks actions that violate I1 to I5 (C7). **Will it wear hardware?** Machine start/stop cycles, power-cap travel and thermal travel are measured for every arm (C12, Manual Chapter 8).

78.3 Security

What authority does it hold? Capacity, replicas, power caps, rollback authorization and routing, only in AUTOPILOT, only through the shield. **Can it expand capacity during a security block?** No: invariant I1 is enforced before execution. **Does it replace encryption, identity or policy engines?** No. Those components are retained (fleet model, security role).

78.4 Finance

What does it save? In the models, energy per run versus the reference autoscaling (C8, class S). On real software the record reads the work, the speed and the machines it took (the Omni index, `results/OMNI_INDEX.md`); more work for the bill is still being measured (`docs/WORK_PER_BILL.md`), and no bill saving is claimed. Fleet-scale figures are modelled (C13); the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

modelled saving comes from reduced idle and padded capacity, not from removing the decision components' own consumption. **What does it cost to run?** C5.

78.5 Adoption

How is it introduced without risk? A week of shadow with no write rights, then one muscle at a time with the reset tested at each handover, then 30 days paired against native in three runs, native on in every arm (docs/PILOT_PROTOCOL.md); on a production system only under a pilot agreement signed with Dubra Software Inc. / The Omni-Compass LLC, and live customer traffic only under the Enterprise License.

78.6 Referees

Was it tuned on the test data? No. Law, shield and baselines were frozen and fingerprinted before the held-out seeds 346410161 and 360555127 (results/PREREGISTRATION.json). **Where does it fail?** Backlog violations against current autoscaling (C11); the engine-dynamics ablation (Manual Chapter 8); open obligations (Manual Chapter 10).

CHAPTER 79

License and Commercial Terms

The software and this manual are licensed under the Omni-Compass Evaluation License (`LICENSE`): evaluation and simulation use only. Everything else - commercial use, production use, operating any system beyond evaluation, redistribution, a hosted or managed service, incorporation into a product or service, or using the software or its results to build a competing product - requires a written Omni-Compass Enterprise License signed by The Omni-Compass LLC and paid for. All patents, copyrights and trademarks covering the Omni-Compass engine, its mathematics and its software have been filed in the United States by Dubra Software Inc. / The Omni-Compass LLC. No patent or trademark license is granted for any other use. Contributions are accepted only on the terms in `.github/CONTRIBUTING.md`, which assign their rights to Dubra Software Inc. / The Omni-Compass LLC.

The copyright in Omni-Compass belongs to Dubra Software Inc. / The Omni-Compass LLC. The source is visible under the Evaluation License, which is not an open-source license; seeing the source grants no right beyond it. The owner of a copyright may grant it under more than one license at once (the Evaluation License to everyone, a paid Enterprise License to a customer), may set the terms of each new version, and may assign the copyright; copies already received keep the terms they were received under. The license texts (`LICENSE`, `NOTICE`, `DISCLOSURES.md`) govern.

Every paper is bound into this book in full, as it stands in the repository, in the chapters that follow this one: the licensing questions and answers, the third-party notices, the standard terms of the Enterprise License (the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

grant, the term, the fees' basis, the warranties and their limits, the indemnities, the audit right, the source escrow and the governing law), the patents and trademarks statements and the security policy; the Evaluation License itself is the License appendix, and the disclosures, declarations and disclaimers stand in the front matter. Where a paper and this chapter differ, the paper governs. The engine's whole source, every Python file the fingerprint `OMNI_V7.json` names, is printed in the Source appendix: nothing in the mechanism is withheld from the owner.

CHAPTER 80

Licensing: Questions and Answers

Plain answers to the questions buyers, engineers and their lawyers ask. The binding terms are in `LICENSE`; where this page and `LICENSE` differ, `LICENSE` governs. Every declaration is in `DISCLOSURES.md`.

Is Omni-Compass open source? No. The source is published so that it can be evaluated, reproduced and audited. It is licensed under the Omni-Compass Evaluation License 1.0 (`LicenseRef-OmniCompass-Evaluation-1.0`), which permits evaluation and simulation only.

What may I do without a commercial license? Evaluation and simulation, free of charge (`LICENSE`, sections 1.4, 1.5 and 2): read the code; run `verify.py`, the simulations and the benchmarks; reproduce the published results and publish your own, every row included (`LICENSE`, section 4); run Omni-Compass in watch, dry-run or shadow mode, or in a test environment, on systems you own or control, where it writes to nothing that serves production traffic or real users and to no physical process outside a test bench. A limited patent license comes with it, for evaluation only (`LICENSE`, section 2.2).

What needs the Omni-Compass Enterprise License? Every commercialization or monetization of any kind; production use; operating any system beyond evaluation; offering it, or its function, as a hosted, managed or software-as-a-service offering; redistributing it; incorporating it, or any part or derivative of it, into a product, service, appliance or firmware; using it or its results to build or train a competing product (`LICENSE`, sections 3 and 5). The Enterprise License is a written agreement signed by Dubra Software Inc. / The Omni-Compass LLC and paid for; its standard terms are summarized in `ENTERPRISE_LICENSE.md` (production, hosted service, OEM and embedded, managed service provider, research).

May I run it as a service for others? Not without an Enterprise License with a hosted-service rider (`LICENSE`, section 3(c); `ENTERPRISE_LICENSE.md`, section 1).

May I connect it to a grid, a plant, a vehicle or a medical device? Not under the evaluation license: such systems may be studied only in simulation. A live connection to any physical system needs an Enterprise License and a written safety case accepted by the system's owner (`LICENSE`, section 10).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

How is the Enterprise License priced? Against the measured gain on the customer's own paired receipts (native against Omni-Compass on the same system, the same load and the same clock). Terms are set in each signed agreement; no price stated anywhere in this repository is an offer.

Are patents involved? All patents, copyrights and trademarks covering the Omni-Compass engine, its mathematics and its software have been filed in the United States by Dubra Software Inc. / The Omni-Compass LLC (`PATENTS.md`). The evaluation license grants no patent license beyond evaluation.

May I use the name or the compass rose? Only to refer to Omni-Compass accurately (`TRADEMARKS.md`).

May I contribute? Contributions require the contributor license agreement (`.github/CLA.md`): every contribution is assigned to Dubra Software Inc. / The Omni-Compass LLC, with a patent license from the contributor.

Does Omni-Compass send data anywhere? No. The software contains no telemetry and makes no network connection of its own except to the systems an operator points it at (a Kubernetes API, `nvidia-smi`, a meter command).

What do scanners report? The license is declared in machine-readable form for Black Duck, FOSSA, Snyk and REUSE (`pyproject.toml`, `REUSE.toml`, `.fossa.yml`, `.snyk`, `sbom/`); third-party components are listed in `THIRD_PARTY_NOTICES.md`.

Can the terms change? Yes. Dubra Software Inc. / The Omni-Compass LLC reserves the right to change the software, its documentation, its results and these terms at any time, without notice; a changed version applies to copies obtained and uses made after it is published (`LICENSE`, section 9). A signed Enterprise License governs its own term.

Which law governs? The laws of the State of Delaware and the federal laws of the United States, with exclusive venue in the Delaware state courts and the United States District Court for the District of Delaware (`LICENSE`, section 19). Dubra Software Inc. / The Omni-Compass LLC is based in Florida.

Who do I contact? Dubra Software Inc. / The Omni-Compass LLC, main office infrastructure, toll-free direct 1-888-339-9551, system route asset 1-888-DEX-YLL-1, landline 321-746-4411 registered in Florida, www.omni-compass.com.

CHAPTER 81

Third-Party Notices

Omni-Compass uses the following third-party components. Each remains under its own license; nothing in the Omni-Compass Evaluation License changes those terms. Installed versions are those resolved from `requirements.txt`.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Component	Use	License
NumPy	numerical arrays	BSD-3-Clause
Matplotlib	charts in the reports	Matplotlib License (PSF-based, BSD-compatible)
ReportLab (open-source edition)	the printable book and reports	BSD-3-Clause
Numba	compiled inner loops of the motion-axis plant	BSD-2-Clause
PyTorch (on GPU machines only, not installed by `requirements.txt`)	the GPU workload of the benchmark	BSD-3-Clause
`tests/third_party/hpa_independent.py`	an independently written HPA reference used unmodified in tests	its own terms, stated in the file
Kokoro-82M v1.0 text-to-speech model and its voice `af_heart` (hexgrad/Kokoro-82M; the int8 ONNX files of thewh1teagle/kokoro-onnx), run by kokoro-onnx; FFmpeg	the recorded voice of the live engine's guided tour (`docs/engine/tour/`, made by `tools/tour_voice.py`): only the clips it read are kept, never the model	Apache-2.0 (the model and its voices); MIT (kokoro-onnx); FFmpeg's own LGPL/GPL, used as a tool and not shipped
Liberation Serif and Liberation Sans fonts (embedded in the PDF book)	typesetting	SIL Open Font License 1.1
DejaVu Sans and DejaVu Sans Mono fonts (embedded in the PDF book)	typesetting	Bitstream Vera / DejaVu license (free)
PlanetLab / CoMon VM CPU traces, March 2011 (`fleet/traces/`, `k8s_controlplane/traces/`; source in their `PROVENANCE.json`)	held-out demand for the modelled fleet	their own terms (public research data); no Omni-Compass copyright is claimed in them
Google cluster-usage traces 2011 (`clusterdata-2011-2`), from which `results/traces/google2011/` is derived (`docs/TRACES_PREREGISTRATION.md`)	the public demand trace on the real cluster	Google's published terms for the traces; no Omni-Compass copyright is claimed in the trace itself

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Component	Use	License
Data-centre footage behind the live engine page (`docs/engine/wall/*.webm`, `*.mp4`, `*.jpg`), cut from *B-roll of Wikimedia Foundation servers at CyrusOne in Carrollton, Texas - photographed in 2015* by the Wikimedia Foundation, via Wikimedia Commons (`docs/engine/wall/README.md` lists every change)	the page's moving background, decoration only	CC BY-SA 3.0 (`LICENSES/CC-BY-SA-3.0.txt`); the adapted loops and stills are shared under the same licence

Kubernetes, kind, `kubectl`, the NVIDIA driver and `nvidia-smi` are not distributed with Omni-Compass; it calls them where an operator has installed them. Their names are the property of their owners (`DISCLOSURES.md`, section 1).

CHAPTER 82

The Enterprise License: Standard Terms

This page summarizes the standard terms of the Omni-Compass Enterprise License, the paid license that every production use, commercial use, hosted service, distribution, OEM or embedded use, and every other commercialization or monetization of Omni-Compass requires (`LICENSE`, section 5). It is a summary for evaluation and planning. It is not an offer, and it binds no one: only an Enterprise License signed by Dubra Software Inc. / The Omni-Compass LLC and the licensee, with its order form, grants any right, and that signed agreement controls over this page in every respect.

82.1 What can be licensed

License	What it allows
Production	The licensee runs Omni-Compass on top of its own systems (clusters, fleets, cards, sites, plants), on premises or in its own cloud accounts, within the scope in the order form
Hosted service	The licensee offers Omni-Compass's function to its own customers as a hosted, managed or software-as-a-service offering, under a hosted-service rider (per customer, per managed unit or revenue share)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

License	What it allows
OEM and embedded	The licensee ships Omni-Compass inside its own product, appliance, firmware or platform, under an OEM rider (per unit or per installed base)
Managed service provider	The licensee operates Omni-Compass for named third parties under a managed-service rider
Research	A university or public laboratory uses Omni-Compass beyond evaluation for non-commercial research and publication, under a research rider

Scope is set in each order form: the licensed systems and their size (machines, cores, cards, sites, muscles or managed units), the fields of use, the territory, the named sites or accounts, and the engine versions covered.

82.2 Fees

Fees are set in each order form: a subscription, a usage-based fee, a share of the measured value captured, or a combination, with any minimum commitment. Where fees track value, the value is measured on the licensee's own paired receipts (native against Omni-Compass on the same system, the same load and the same clock), by the method the order form names. Payment terms, taxes and late charges are as the order form states. No price, rate or benchmark in this repository is an offer.

82.3 What the licensee receives

1. The licensed engine at a named, sealed version (its fingerprint, `tools/omni_version.py`), and each later version the subscription covers.
2. The wiring kits and the plug for the licensed systems, the manual and the book, and the receipts tooling.
3. Support and maintenance at the tier in the order form: response targets, named contacts, and corrections of defects that reproduce on the licensed version.
4. Installation through the manual's levels: read-only first, the wire check, a watch arm equal to native, then writing levels one at a time, each with its receipt.

82.4 Warranties

1. **Conformance.** For the warranty period in the order form, the licensed version performs materially as its documentation describes. The remedy is correction or, failing that, a refund of the fees paid for the nonconforming version for the affected period.
2. **The safeguards.** The kill switch hands every setting back to the value read before Omni-Compass's first write; the shield keeps every write inside the cover the operator granted; Omni-Compass never fights another writer.
3. **No other warranty.** No outcome, saving or result on the licensee's systems is warranted. Published results are evidence about the systems they ran on (`DISCLOSURES.md`, section 2).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

82.5 Intellectual property

1. Dubra Software Inc. / The Omni-Compass LLC keeps all right, title and interest in Omni-Compass, the Mechanism and the marks. The licensee receives the rights its order form lists, for its term, and no others.
2. **Patent license.** The Enterprise License includes a license under Dubra Software Inc. / The Omni-Compass LLC's patent rights in the filed applications, and in any patent issuing from them, for the licensed scope.
3. **Infringement indemnity.** Dubra Software Inc. / The Omni-Compass LLC defends the licensee against a third-party claim that the licensed version, used as licensed, infringes that party's intellectual property, and pays the damages finally awarded or the settlement it agrees, subject to prompt notice, control of the defense and the usual exclusions (modifications, combinations, unlicensed use, versions superseded by an offered fix). Remedies may include a license, a modification or a refund.
4. **Confidential filings.** The patent application number and other confidential information are disclosed to a licensee under the agreement's confidentiality terms.

82.6 Limits of liability

Each party's liability is limited to the fees paid or payable in the twelve months before the claim, and neither party is liable for indirect, incidental, special, consequential or punitive damages, except for the exclusions the signed agreement states (for example, breach of confidentiality, the infringement indemnity, and the licensee's breach of the license scope).

82.7 Confidentiality, data and security

1. **Confidentiality.** Mutual, for the term and a period after it, covering non-public information either party gives the other.
2. **Data.** Omni-Compass contains no telemetry. The licensee's data, readings, settings and receipts stay on the licensee's systems and remain the licensee's. Where the licensee chooses to share data for support, a data-processing agreement applies.
3. **Security.** A software bill of materials ships with every version (`sbom/`); vulnerabilities are handled under `SECURITY.md`; the licensee may run the verifier (`python3 verify.py`) and the seal checks on every delivered version.

82.8 Safety and operation

1. The licensee remains the operator of its systems. The machines' own controls and protections stay in place; Omni-Compass sets only values they already accept.
2. Any connection to a physical system (grid, plant, vehicle, robot, medical device, facility) requires a written safety case accepted by the system's owner and every review its regulator requires; safety-critical systems are licensed only on those terms.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

3. The kill switch stays operable at all times.

82.9 Compliance, audit and insurance

1. Each party complies with export-control, sanctions and anti-corruption law.
2. The licensee reports usage against the licensed scope as the order form provides, and Dubra Software Inc. / The Omni-Compass LLC may verify it on reasonable notice, no more than once a year.
3. Insurance, where the order form requires it, is carried by each party at the limits stated there.

82.10 Term, renewal and transition

1. Term and renewal are as the order form states.
2. On termination or expiry, the licensee stops use, every setting Omni-Compass changed is handed back to native (the hand-back is built into the engine), and every copy is returned or destroyed; transition assistance is available at the rates in the order form.
3. Source-code escrow for the licensed version is available under a three-party escrow agreement.

82.11 Governing law and precedence

The signed agreement states its governing law and venue; the standard is the law of the State of Delaware, with venue in the Delaware state courts and the United States District Court for the District of Delaware. Its order of precedence is: the order form, then any rider, then the Enterprise License terms, then the documentation. This page and the evaluation license (`LICENSE`) are superseded by the signed agreement for the licensee and its scope.

82.12 How to obtain one

Dubra Software Inc. / The Omni-Compass LLC, main office infrastructure, toll-free direct 1-888-339-9551, system route asset 1-888-DEX-YLL-1, landline 321-746-4411 registered in Florida, www.omni-compass.com. A license starts with an evaluation on the licensee's own systems (`LICENSE`, section 1.4): watch mode, the wire check, and paired receipts on its own load.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

CHAPTER 83

Patents and Trademarks

83.1 Patents

All patents, copyrights and trademarks covering the Omni-Compass engine, its mathematics and its software have been filed in the United States by Dubra Software Inc. / The Omni-Compass LLC.

The filings cover, among other things, the Omni-Compass engine (the six-state closed law and its bounded control command held through the integration step), the compass law (the service position pulled to the middle of its band by a bounded push and pull, with fail-up at the wall), the antagonist up/down wiring of each muscle, the plug contract (one restore point, read-back, the one-writer rule), the two-wire governance of a processor (clock ceiling and power limit), the two-way nervous system that grants and withdraws authority per organ, and one governor over many machines and realms on one clock.

83.1.1 What has been filed

Application	a nonprovisional utility patent application under 35 U.S.C. 111(a), filed with the United States Patent and Trademark Office
Title of the invention	**The Omni-Compass**
Inventor	Alan John Dubra, Kissimmee, Florida, United States
Drawing sheets	15
Application data sheet signed	20 September 2026 (form PTO/AIA/14, 37 CFR 1.76)
Publication	normal eighteen-month publication requested
Application number	withheld here on purpose; the filing is verifiable with the USPTO and is shown to a licensee under a signed Omni-Compass Enterprise License

The application data sheet names no assignee; the application stands in the inventor's name. Any assignment to The Omni-Compass LLC is recorded with the USPTO separately (37 CFR part 3).

No patent license is granted by publishing this repository, by the evaluation license, or by any act of The Omni-Compass LLC other than a signed, paid Omni-Compass Enterprise License. Use outside the evaluation license is infringement. Everyone who downloads, forks, scans or runs this software is on notice of these filings.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

83.2 Trademarks

All patents, copyrights and trademarks covering the Omni-Compass engine, its mathematics and its software have been filed in the United States by Dubra Software Inc. / The Omni-Compass LLC.

83.2.1 The marks

"Omni-Compass", "OmniCompass", the Omni-Compass compass rose with its ring of Greek letters, and the related names, logos and trade dress (the "Marks") are trademarks of Dubra Software Inc. / The Omni-Compass LLC; trademark applications have been filed in the United States. Neither the evaluation license (`LICENSE`) nor publication of this repository grants any license to the Marks. A license to use them is granted only in a signed Omni-Compass Enterprise License, and only as it states.

83.2.2 What is allowed without a license

- Referring to Omni-Compass by name, accurately and in plain text, to say what it is, that you evaluated it, or that a result was produced with it, with the engine version and commit (`LICENSE`, section 4).
- Linking to the repository or to www.omni-compass.com.

83.2.3 What is not allowed

- Using any Mark, or anything confusingly similar, in the name of a product, service, company, domain, account, package, repository, fork or derivative.
- Using the logo or the compass rose, or altering any Mark.
- Suggesting endorsement, sponsorship, certification, partnership or affiliation by Dubra Software Inc. / The Omni-Compass LLC.
- Using a Mark in advertising, comparative claims or sales material without a signed license.

83.2.4 Other companies' marks

Kubernetes is a trademark of The Linux Foundation; NVIDIA is a trademark of NVIDIA Corporation; KEDA and Karpenter are projects of their maintainers; other names belong to their owners. Their mention describes compatibility or a system Omni-Compass was tested with; it states no affiliation, endorsement or certification (`DISCLOSURES.md`, section 1).

83.2.5 Reporting misuse

Dubra Software Inc. / The Omni-Compass LLC, main office infrastructure, toll-free direct 1-888-339-9551, system route asset 1-888-DEX-YLL-1, landline 321-746-4411 registered in Florida, www.omni-compass.com.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

CHAPTER 84

Security Policy

84.1 Reporting a vulnerability

Report a suspected vulnerability privately to Dubra Software Inc. / The Omni-Compass LLC by telephone at its main office infrastructure (toll-free direct 1-888-339-9551; system route asset 1-888-DEX-YLL-1, landline 321-746-4411 registered in Florida) or through www.omni-compass.com, never in a public issue, pull request or discussion. Include the version and commit, what you saw, how to reproduce it, and its likely impact. We acknowledge reports, keep the reporter informed, and coordinate disclosure: a fix or a mitigation is published before the details are, and the reporter is credited if they wish. Please give us a reasonable time to fix before any disclosure, do not access data that is not yours, and do not disrupt any system; good-faith research that follows this policy will not be pursued by us.

84.2 What is in scope

The engine, the controllers, the plugs and wiring, the harnesses, the workflows and the verifier in this repository. Third-party software Omni-Compass runs on or connects to (Kubernetes, KEDA, Karpenter, NVIDIA drivers, databases) is reported to its own maintainers.

84.3 How Omni-Compass is built to fail safe

- The governor issues control actions only through the shield (`omnicompass/shield.py`, `cpp/src/shield.cpp`), inside the cover the operator granted, and never fights another writer.
- It snapshots every setting once, before its first write, and the kill switch (`python3 tools/omni_switch.py off`) hands every setting back; a dead-man lease hands them back if the governor stops.
- It runs under least privilege: on Kubernetes, a service account with `kubectl auth can-i` receipts for what it can and cannot do (`deploy/kind/rbac-omni.yaml`).
- The watchdog acts only on registry records its own user wrote that no other user can change, and never signals a process number the system gave to another process (`tools/omni_switch.py`). Put the switch and the registry in a directory only the governors' user can write (`OMNI_MASTER_OFF`, `OMNI_REGISTRY`); `status` warns when they are not.

- It contains no telemetry and makes no network connection of its own except to the systems an operator points it at.
- The threats of misuse, the guards against each and what is still open are set out in `docs/THREAT_MODEL.md`.
- Every release carries a software bill of materials (`sbom/`) and a seal of the engine and its twins (`results/SEAL.json`, `python3 verify.py`).
- The capture script (`fleet/capture/kube_capture.sh`) is read-only; no component writes to a live cluster unless the operator starts it in a writing mode.

CHAPTER 85

Repository Standards

The files the leading repositories carry, the open ones such as Kubernetes and the source-available, commercially licensed ones such as HashiCorp Terraform, Elastic, MongoDB, Redis, CockroachDB and Sentry, and where Omni-Compass carries each. Omni-Compass is published for evaluation and simulation; everything else is licensed (`LICENSE`, `LICENSING_FAQ.md`).

What a leading repository carries	Omni-Compass
License, machine-readable and in full	`LICENSE`, `LICENSES/LicenseRef-OmniCompass-Evaluation-1.0.txt`, SPDX headers, `REUSE.toml`
Licensing questions in plain words	`LICENSING_FAQ.md`
Notices and third-party components	`NOTICE`, `THIRD_PARTY_NOTICES.md`
Disclosures and disclaimers in one place	`DISCLOSURES.md`
Patents and trademarks	`PATENTS.md`, `TRADEMARKS.md`
Contributor license agreement	`.github/CLA.md`

Reproducibility: fingerprinted release, sealed twins, checksummed results	`RELEASE_MANIFEST.json`, `results/SEAL.json`, `SHA256SUMS.txt` in every result folder
Rules written before every benchmark run	`docs/GPU_PREREGISTRATION.md`, `docs/REALMS_PREREGISTRATION.md`, `docs/K8S_COMPASS_PREREGISTRATION.md`
A manual and a printable book	`docs/OMNI_COMPASS_MANUAL.md`, `docs/OMNI_COMPASS_MANUAL.pdf`
Every result in one place, with charts	`docs/DOSSIER.md`
A one-file archive of the repository	GitHub's Download ZIP, at any commit (the copyright deposit is `release/copyright/`)

Files present at the commit this page describes; `python3 verify.py` checks the ones the results depend on.

CHAPTER 86

Python, C++ and the Seal

The laws are twinned: each has a Python version and a C++20 version that give the same answers, proven by a parity test on every build (`cmake -S cpp -B cpp/build && cmake --build cpp/build`).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Law	Python	C++	Proven by
core engine	`omnicompass/core.py`	`cpp/src/core.cpp`	500 frozen fixtures
the supervisory loop (the adapter)	`omnicompass/adapter.py`	`cpp/src/governor.cpp`	`tests/test_cpp_governor_parity.py`
safety shield	`omnicompass/shield.py`	`cpp/src/shield.cpp`	`tests/test_cpp_shield_parity.py`
HPA replica law	`fleet/harness.py`	`cpp/src/hpa.cpp`	`tests/test_cpp_hpa_parity.py`
closure law	`omnicompass/closure.py`	`cpp/src/closure.cpp`	`tests/test_cpp_closure_parity.py`
conveyance law	`omnicompass/conveyance.py`	`cpp/src/conveyance.cpp`	`tests/test_cpp_conveyance_parity.py`
nervous system	`omnicompass/nervous_system.py`	`cpp/src/nervous_system.cpp`	`tests/test_cpp_twins_parity.py`
compass and ledger	`omnicompass/compass.py`, `storage.py`	`cpp/src/compass.cpp`	`tests/test_cpp_twins_parity.py`
GPU governor rules	`omni_controller/gpu_governor.py`	`cpp/src/gpu_rules.cpp`	`tests/test_cpp_twins_parity.py`

The seal (`results/SEAL.json`) holds the SHA-256 fingerprint of every twinned file, written only after every parity test passes. `verify.py` fails, naming the file, if any sealed file changes afterwards. The compass law (`omnicompass/compass_law.py`) and the two-wire GPU governor are in Python today; their C++ twins are next.

Why two languages. A law that exists in one implementation can hide a bug that is also its behaviour: the tests pass because the tests were written against the same code. Two implementations written separately, in languages with different numerics and different defaults, that agree to fifteen decimal places on five hundred trajectories and on every fixture of the governor, the shield, the HPA law, the closure, the conveyance and the nervous system, are evidence that the text of the law is what both compute. The C++ twin is also the one a buyer would embed where Python does not run (a controller, a firmware, a PLC), and the soak (`results/SOAK.json`, one hundred million decisions, no failure) is run on it. The seal makes the twins' agreement a property of the repository rather than a claim: change a sealed byte and `verify.py` fails, naming the file.

The three fingerprints. The seal fingerprints the twinned laws; `OMNI_V1.json` to `OMNI_V7.json` fingerprint the engine as a whole (law, controllers, muscles, runners: 38 to 46 files); `RELEASE_MANIFEST.json` fingerprints the release (the commit, the engine, the twins, the GPU protocol,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

the live evidence and the verification receipt) and is rewritten by `tools/release_manifest.py` before every push, under the Python GitHub runs. A reader holding any one of the three can tell whether the files in front of them are the files the results were made on.

CHAPTER 87

The Founder's Working Notes

Where a sentence is a design aim rather than what the code does today, or a figure that is not yet measured, the check column says so. Nothing in this chapter adds a result: every number that is a result names the file it comes from.

87.1 What Omni is

OmniCompass is the governor. It is the process running on the processor, and the chip executes it. The card, the replica count, the rack cap, the joint and the feeder are the levers: the muscles. Omni reads the meters, steps a bounded loop, and writes only the lever it is allowed to write. When it stops, it puts that lever back.

It is not the chip, not the card and not Kubernetes. It is the brain on the host, writing through a bolt.

Governor is the machine word. A governor on a steam engine did not build the engine and did not turn the shaft. It watched the speed and moved the throttle so the speed stayed in a band. The plant does the work: the chip, the card, the pods, the job. Omni reads a meter, writes one lever, and puts that lever back.

87.2 The loop

The chapter says	The code today	Check
Omni reads the plant's meters and maps them to the state E, U, S	`omnicompass/adapter.py`, `observe_vector` and `assimilate`	matches
It computes the drift with the command at zero, then raw = −drift + K[P]·(σ − U), clipped to the authority before the step	`omnicompass/core.py`, `control_command`: `u = clip(−f_U(x,t) + KP·(σ − U), ±U_AUTHORITY)`	matches
It holds that same u through every RK4 stage and does not rewrite U afterwards	`core.py`, `macro_step`: one `u` per micro step, passed unchanged into all four RK4 stages; U is never overwritten	matches (proved: `docs/TRACKING_THEOREM.md`)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The chapter says	The code today	Check
It writes the clipped command u to the lever	**Not today.** The frozen live governor runs the engine with u = 0 (`macro_step(..., target=None)`) and uses u only as its convergence signal (`push = u / U_AUTHORITY`). The lever is set by the allocation law and the nervous system's authority (`omnicompass/nervous_system.py`).	**design aim**, see "What to strengthen"
On exit it restores the lever	kill switch: `omni_controller/controller.py` restore; the GPU bench restores and reads back the start limit; the realm harness checks every knob is handed back	matches

So the step the chapter describes is the engine's own step, and it is proved. Writing u itself onto a lever, through an output map with a gain in watts (or replicas) per unit of u, is a further mechanism. It is not what produced the results below.

87.3 Wiring

A wrist wire moves the wrist. It does not move a finger that has its own tendon unless that tendon is also wired.

The card's clock wire goes to the NVIDIA driver. The replica wire goes to the Kubernetes API. The scheduler's wire goes to the kubelet. Those wires already exist and do not pass through Omni. Omni is an added process, and a tendon is connected to it only if the output map writes that lever and the input map reads it back.

A power-limit write can make the driver drop clocks. That is a side effect on one finger, not the replica nerve, which keeps running on its own path unless a second line is connected. The cluster starts its own wires: the API server accepts a replica write, the scheduler places the pod, the kubelet starts it, the driver moves the clocks, and HPA, if installed, is its own process. Omni joins those nerves. It is a client of the plant, not its origin.

87.4 Four realms, five organisms

1. Compute / AI / Cloud: GPU server, Kubernetes, the card, the job.
2. Physics / Robotics / Autonomous: joint, servo, PLC, car, line.
3. Energy / Facility / Industrial: rack, cooling, PDU, battery.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

4. Distribution / Specialized: network, feeder, logistics.
5. The whole organism: all 656 canonical muscles, each once, one clock.

A muscle may sit in more than one realm. Every realm stands on the same spine (Kubernetes, machines, GPUs and CPUs, network, storage, observability, security, cooling, electrical distribution), and then has its own domain muscles. The fifth run holds each of the 656 once.

Each organism is shown native, then with Omni, on the same membership, the same seed and the same clock: two receipts. The core does not change when the lever changes.

Check	
Built	`realms/` (round 3): spine of 190 muscles in all four realms; organisms of 345, 262, 282, 337 and 656 (`docs/REALM_MUSCLES.md`)
Result	Whole organism +0.1% work per energy, SUPERIOR WITHIN GUARDRAILS; the realms pay in service when they share the spine (`results/realms/REALMS.md`)
Limit	These are modelled plants (evidence S / rung E2). A catalog row is not a tendon. GitHub can host the compute organism for real (kind, and the GPU on a rented card); facility, machine and grid need their own hosts
Open	The 656 is a working catalog, not a census: `docs/realm_study/` checks it against the real systems' documentation and industry practice (waves 1 and 2 done; wave 3 maps every row)

87.5 Evidence rungs

Rung (chapter)	Class (repository, `docs/EVIDENCE_LEDGER.md`)	Meaning
E0	design	the written spec
E1	T / V	deterministic tests and proofs: Python against the C++ twin, the tracking theorem
E2	S	simulation on a made plant (the realms, the fleet and GPU models)
E3	L	real software: Kubernetes on kind, no card (sets 22 and 23)
E4	P	a physical meter: the card's own power reading (the GPU bench; first run on an NVIDIA A10, 2026-10-02, `results/gpu/run-20261002T082232Z/GPU_REPS.md`; the corrected governor not yet run on a card)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

A result does not climb a rung by itself. The four realms are plants; E1 to E4 are how hard the proof is on whichever plant is run.

87.6 What blocked the card

The hash did not stop the card. A Python–C++ mismatch can fail a test after a machine has started the job; it cannot stop GitHub from handing out a machine, because the runner is chosen before the code runs. The verify job started and failed (fixed since: it is green), and separately the GPU job never got a machine.

The organisation's and enterprise's settings show no GPU runner and no option to create one (checked 2026-10-02), so no budget could start it. The run therefore moves to a rented card (`scripts/gpu_rented_run.sh`, one command).

87.7 The bake-off that exists

Set 23 (`results/live/LIVE_REPS_23.md`, run 36940088922): real Kubernetes, ten pairs, fifteen minutes an arm, the same open-loop work, native against Omni, six kind workers, order rotated.

Gauge	Native	Omni	Change
Response, 95th percentile (ms)	327.3	123.8	−62.2%
Response, 99th percentile (ms)	503.4	169.3	−66.4%
Response, mean (ms)	146.6	80.1	−45.4%
Failed requests	0	0	0
HPA replicas, mean	8.51	5.40	−36.6%
Workers in service	6	4.28	−28.7%
Pods started	4.7	1.7	−63.8%
Pod start wait (s)	18.6	3.8	−79.6%
CPU, service plus Omni (cores)	0.903	0.894	−1.0% (no difference)
Energy, workers still on (Wh, declared model)	159.0	158.7	−0.2% (no difference)

The same requests were sent and none failed. They were answered faster, on fewer copies, at the same bill. Kind leaves every worker powered, so the watt line stays flat. Parking a worker and waking it again was tried; the churn ate the saving (`docs/CLAIMS_REGISTER.md`, C17), so that path is closed on this plant.

Arithmetic, not a result: if a run finishes 5% more work, nineteen runs do what twenty used to (20 / 1.05 = 19.05).

87.8 The chip

The card is the meter that can move the electric bill, and the meter that can move output.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Energy on the chip is the integral of power.draw. The same pile can be spent two ways:

- **Output:** more finished work on the same bill. The cap stays near where the native arm left it, the draw stays in the same band, and heat gets no new reason to rise.
- **The bill:** a lower enforced limit, the job still finishes, and joules fall.

A company short of cards spends it on output. A company paying for GPU hours with spare capacity spends it on the bill. A company against a building power cap splits it. The bench's primary outcome, work per joule, counts both, and its table prints requests and joules separately, so the receipt shows which way the pile went (`tools/gpu_reps.py`).

For the pile to be real:

- the cap has to bind;
- the write has to be enforced by the driver, and the enforced limit read back;
- the job has to finish;
- the limit has to be restored on exit, so the next native arm is not still capped.

All four are in the bench and its preregistration (`docs/GPU_PREREGISTRATION.md`, amendments 1–3).

87.9 The babysitting tax

The electric bill is the small pile. The babysitting tax is the people and tools kept on the clock to watch the levers, reset a cap, and stop the muscles fighting. A card's real cost is usually the card and the hours it sat idle or late, not the electrons.

What fills the seat today is a person: someone sets the cap, someone gets the page when it is left down, someone turns it back after the run or the crash. The product takes that knob and that page.

87.10 What we found nobody selling

We found no published product that does all of the following across compute, machines, facility and grid as one governor:

- reads all of their meters into one state;
- holds one clipped command through the step;
- puts each lever back when the run stops, and prints both receipts.

Borg, Twine and OpenShift govern compute. AWS is a cloud. Turbonomic covers the IT stack. Tesla runs the car, the battery and the factory as separate software. Each covers more than one thing as a company, not four realms as one governor.

Omni on such a stack does not replace it: Borg remains the muscle. This is a market observation from public material, not a claim tested here.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

87.11 The bill

Run the stack native and print the receipt. Run the same stack with Omni and print the receipt. The difference is the pile, and the fee is 20 percent of it.

On a stack that costs $100, a 10 percent win is $10. The fee is $2, and the customer keeps $8. In general, the fee is 0.2 × (measured win) × (spend). A gain and a cut are the same difference, read from opposite sides. Do not add CPU, GPU and babysitting percentages into one bill: the invoice is one pile.

Check: the 10 percent is an example, not a measured win. What is measured so far:

- on Kubernetes, response time −62% at the same energy (set 23);
- in simulation, +0.1% work per energy for the whole organism (realm round 3);
- on a card, nothing yet: the GPU bench is the first real-meter number.

Revenue figures should be computed from the measured win on each customer's own receipt. The per-company table in the working draft (2% of each company's published infrastructure spend) assumed a 10% win everywhere, and several of its spend figures do not match the companies' published capital expenditure. It is left out of the repository until both are sourced.

87.12 What to strengthen

1. **Wire the output map.** u becomes one lever, read back and restored, with the start value, the written value and the value after a kill printed on the receipt. The GPU bench already records the start limit, every write and its read-back, and the restored limit. A u-to-lever output map (a gain in watts or replicas per unit of u) is a new mechanism. It would be preregistered and tested as its own arm, first in the realms, then on a card, never mixed into the frozen confirmation run.
2. **Keep the step as it is:** clip before the stage, hold u through RK4, do not rewrite U (proved: `docs/TRACKING_THEOREM.md`).
3. **Run native against Omni on the same membership for each realm.** Compute is the one GitHub can host for real; the other three are modelled until their hosts exist.
4. **Aim the chip at about 5% more finished work on the same bill**, cap unchanged and temperature never behind, or at fewer joules for the same work. The buyer chooses, and the receipt prints which.

CHAPTER 88

The Road to the Engine That Stands: Omni v5, v6, v7, v8, v9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24 and 25

88.1 Omni v5 — the engine fingerprint

omni-v5 is a distinct engine, its own tree, no longer read as v3. It is fingerprinted file by file in `OMNI_V5.json` (`tools/omni_version.py`); `python3 tools/omni_version.py` prints `omni-v5` on this checkout. v1, v2 and v3 stay frozen, each kept for its own results; no result is ever read across versions.

88.1.1 The default brain: the max (12 October)

The founder's order of 12 October: "We're going to show a benchmark that shows it to the max. And we're going to show one native... anybody can tune it from the max down." v5's default (`V5CFG`) is therefore **the max**: every muscle pushed toward its own limit for the most work, faster, never past its limit and never below native. The energy that takes is reported as **LOSS**, beside the work and the speed it bought; the max never shaves (nothing is taken from one muscle to give to another). The dial turns it down: **the tune-down** (`V5SAVE`, the save setting described below) is native's work on the least energy, kept and tested on every muscle.

- **A pool** gets the machines its forecast needs before the rush lands: the recent peak arrivals widened by the largest rise the pool has shown within one machine start, at 95% utilisation, plus any **work waiting in line** cleared within one machine start, through a floor under its own autoscaler, never fewer than its **twin** runs (the brain's model of native: the same pool under its own autoscaler alone, on the same arrivals). The machines it added and no longer needs go back at once (a ceiling at the larger of its need and its twin's count; the autoscaler's own scale-down would hold them for its window). Its power cap and admission stay native: full clock, every request admitted.
- **A room** is cooled ahead of the heat as it nears its limit or its cooling nears flat out, never warmer than native.
- **A battery site** clips its line from its charge, native plus: the operator's own reserve while nothing would cross, and below it, down to its band's floor, exactly the draw that would cross; a UPS lends only the charge above its outage floor.
- **A motion axis alone**, while tasks are waiting, runs at **its own peak speed** (`s_peak`, `realms/presets.py`: the head the machine itself has above the everyday profile native runs: a joint's

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

drive and a multirotor's airframe 1.25, a road vehicle's drive 1.25, a ship's engine to its maximum continuous rating 1.15), never past it, back to the everyday setting at once when its motor passes 80% of its heat rise or its tracking error passes half its line. A reaction wheel's saturation, a train's line speed and an elevator's overspeed governor are their limits: those stay native. Inside a body an axis keeps its everyday speed (see the bone). Torque (effort) limits stay native: in these models a higher one changes nothing.

- **A process loop** native already runs flat out (the full actuator): wired, watched, native.
- **At its limit on native.** Every power limit at full, every admission gate open, a loop's actuator at its full range: native already runs these at the top of their range, the max writes nothing, and the tables say so in those words (`native_at_limit`).
- **The bone.** Inside an organism the body's lines (each site's grid line, each room's cooling and its degrees to its limit) are loaded by the whole body, so the max grants machines and cooling only out of the room the most loaded line has left, one decision ahead (its latest reading plus the larger of 3.09 of its own wobbles and the largest single climb it has shown, counted on the line without the max's own machines: its own steps are not the line's wobble). A machine is started only if the lines can still carry it when it is ready (the climb grown by the square root of its start time: one started and then cancelled only burns its start). A site with flexible load waiting gives its catch-up the room first. With no room, what the max added goes back, as much as the shortfall needs, the pools with the most extra first and the machines started last first, never below a pool's twin. An axis inside a body keeps its everyday speed: at the peak hour the organisms run, the bone almost never has room for its worst case, and in the development runs its peak gave the body nothing while its changed rhythm crossed neighbours at their own limits.
- **One pedal.** Push for more, lift off for less; lifting hands the setting back toward native. At idle the pool lifts all the way to its breathing floor (two machines) and wakes straight to the work. **The lease**: at 80% of every modelled run the brain is cut and the plug walks every setting back to native over 24 decisions (no jump the body must absorb at once); a floor that only held a pool at its twin's count adds nothing to walk back and is let go at once (a walking floor would hold machines native had already released). The security kill switch is instant.
- **Wear** is metered beside the work, never judged: a pool's machine-hours, a room's cooling unit-hours, a battery's kWh cycled, an axis's motor heat (degree-hours above ambient), a loop's actuator duty-hours.
- **Three loads**, fixed before the preregistered run (seeds 3000-3009): each organism's own load, **the climb** (the load stepping 1 2 3 2 3 4 ..., up to twice its own), and **the line** (`LINE` in `realms/harness.py`: work already waiting when the run starts, a quarter of the work the run itself brings; a pool's jobs, an axis's tasks, a site's held-over flexible load; a room's heat and a loop's demand cannot wait and have none). Every muscle alone runs its own load and the line; the organisms run all three. Speed is judged where there is a line: the arm that clears it sooner is faster.
- **The live controllers** carry the same dial (`--dial max`, the default): the Kubernetes controller holds the service well inside its line (the compass at 0.3) and never gives back a machine the cluster had on its own;

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

the GPU compass keeps the card's clock ceiling at the top while it serves (the card already runs flat out on its own power limit).

The organisms run the hour around each battery site's daily peak, where the UPS lines carry most of their rating: there the bone is tight and the max gives only what the lines can carry. Every muscle alone has no body around it, so the max gives it everything its own limits allow. `results/realms_v5/REALMS_V5.md` shows both, and the climb (the load stepping 1 2 3 2 3 4 ..., up to twice the organism's own) where native breaks first.

88.1.2 What v5 is

v5 is **a combination of everything**: it takes v3's proven engine (its live controllers, its realms and organisms, its runners) and adds the **v5 compass law** (`realms/compass_arm_v5.py`) and its arm in the harness (`realms/harness.py`). The goal is to be equal to or ahead of native and every prior version on every measure, and never behind on any — *do no harm*.

The v5 muscle catalog (`realms/catalog_v5.csv`) is **1,107 muscles in 70 families** — v3's 945, then a first wave of six new families of real control points: **Linux Kernel & OS Control** (cgroups, the CFS scheduler, DVFS/cpufreq, transparent hugepages, the I/O scheduler, NUMA balancing, dirty-ratio writeback, swappiness, TCP buffers, …), **Serverless & Functions (FaaS)**, **Virtualization & Hypervisor**, **Content Delivery & Edge Cache**, **Gut** (data-plane intake and waste), and **Skin** (perimeter and admission); then a second wave (12 October) of 95 muscles: five new families, **Financial Markets & Trading Systems** (matching engines, order gateways, pre-trade risk, market-data fan-out), **Media Streaming & CDN** (transcoders, packagers, origin shields, player buffers), **Game Servers & Real-Time Interactive** (Agones fleets, tick rates, matchmaking, relays), **Blockchain & Ledger Nodes** (a node's cache, mempool, peers and validation threads; never a consensus rule) and **CI/CD & Build Farms** (runner scale sets, build concurrency, caches, test shards), plus additions to seven families already there: security engines (an intrusion-detection system's capture threads and ring buffer, a web firewall's inspection workers, a SIEM's ingest), MQTT brokers, DNS and mail caches, ROS 2 executors, humanoids and manipulators, warehouse robot fleets, PX4 and ArduPilot drones and swarm spacing, and edge sites. The GPU family is named for the hardware, not one vendor (**GPU Hardware**), and the eight audited families carry numbers (64 to 71) like every other family. Each is a distinct real-world knob, modelled on the matching plant template, exactly as v3's 945 already share five templates. A third wave (12 October, night) adds the founder's nine open-source pieces as ten muscles, each in the spine family its knob belongs to (`docs/THE_SEAT.md`): Kepler's energy reading driving a pool's target (Kubernetes Workload Scaling), Climatik's inference power cap, Adaptive GPU Power Capping and NVIDIA's platform power budget (GPU Hardware), EAR's CPU frequency policy and global energy budget and the Kubernetes Power Manager's core profiles (Host CPU & Memory), CruiseKube's and Goldilocks's request rightsizing (Container Resources) and PEAKS's power-aware placement (Kubernetes Placement & Scheduling). The organisms on v5: Compute / AI / Cloud 540, Physics / Robotics / Autonomous 404, Energy / Facility / Industrial 480, Distribution / Specialized 484, the four stacked 1,908, the whole tower 1,107; the spine all four realms share is 267. (v3's own catalog `realms/catalog.csv` stays 945, frozen for v3's results.)

Two math-only guardrails, and otherwise free arms:

- **The edge** — a per-knob cushion that widens at once when service climbs and narrows slowly when it falls (`cushion = climb × reaction + z × wobble`), so nothing riding its own limit falls off.
- **The centre / the hole** — nothing is eased into a pit it cannot climb out of. A cooled zone is eased only by the degrees its cooling can still recover (the Lindley reach), and not at all while its cooling headroom is falling toward empty faster than the cooling can answer. A process loop's setpoint never sits closer to its band's edge than the loop's own largest swing toward that edge (the loop reach, read from the historian's low and high over each decision, carried ahead for a slow loop). A serving pool is never capped below the largest jump in demand it has shown (the drop floor) nor so far that a burst would push its responses over the line where native's would not (the latency floor). And nothing permanent: a machine handed back to a cloud is the cluster autoscaler's own decision, because the autoscaler shrinks from wherever it is left, so an early hand-back would leave the pool a machine short of native for good; and a motion axis is slowed only while the wake forecast over a whole deadline (the most that can arrive in one deadline at the recent peak rate) still finishes inside that deadline at the slowed speed, so a delay is always recovered before a later rush could make it permanent. When work comes, every muscle wakes straight to the level the work needs (the founder's rule: from idle straight to 99, never past 100).

Every other knob is free to move both ways inside its physical cover, generating units included (a unit's steam, speed or gate loop eased inside its band serves the same load with less effort), and **a knob stays native only where its own physics says moving it cannot help without harm**: an interactive pool's power cap (its response line is shorter than one decision, so a cap's one decision of slower service cannot be seen and undone inside the line; the metered GPU, class P, is where that cap is proven), a battery's peak-shave (round-trip energy bought for service), and a cloud pool's machine hand-back. A batch queue's, a training job's or a terminal's power cap is free under the drop and latency floors.

Amendment, 12 October. The first v5 table (commit `c0e80a852`, the whole tower +0.0%) ran an engine that held every generating unit's loop, every power cap and every inverter native by blanket gates. The gate on generating units alone threw away almost all of what v5 saves: on the tower, 1.09% with it off against 0.04% with it on, on development seeds. v5 was re-declared with the gates replaced by the physics floors above, developed on seeds 7100-7209 only, and the preregistered seeds 3000-3009 were run again unchanged.

Amendment 2, 12 October. The catalog's second wave (95 muscles, five new families and additions to seven) took it to 1,097 muscles in 70 families; the engine's law is unchanged, its fingerprint re-declared because the catalog is part of it. Developed on seeds 7100-7109 only (0 of 1,097 LOSS or power given, all six organisms superior); the preregistered seeds 3000-3009 were run again unchanged on commit `04d9eb3b3`, with the same savings on the whole tower, the four stacked and Energy / Facility (3.0 times v3's).

Amendment 3, 12 October (night): the living body. The founder's order of 12 October: "whatever one muscle is having a problem, the other muscles kick in ... the brain and nervous system to activate its immune system ... nothing can be locked." The engine now carries, as properties of the code (`docs/FORMAL_V5.md`, section 4): a native twin of every room (the brain's sense of the temperature native

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

would leave it at, exact by construction), the room's own knob curing it where it can and the body's heat debt handing back the max's machines where it cannot (V8, V11), every battery's charge counted as room only while it lasts and its discharge timed for its line (V6, V12), no machine taken from a queue that needs it (V7), a pull-down handed back gradually and granted only where it can be held (V9, V10), and every forecast starting at the plant's first reading (V13: a lock that kept every battery's timed discharge shut for the whole run, and a room twin that started wrong, both removed). The catalog's third wave took it to 1,107 muscles. Developed on seeds 7100-7199 only: under the climb, plants with less work or more misses inside the four realms fell from 19 to 0 in 400 organism runs while the misses fell about twice as far as before; on seeds 7100-7109 every muscle alone and the six organisms on all three loads showed 0 muscles and 0 plants with less work or more misses. Fingerprint re-declared (digest `9be48445438943c2`); the preregistered seeds 3000-3009 were run again unchanged.

Amendment 4, 13 October: every muscle its own card. The founder's question of 12 October, night: does every muscle have its own tuning, maxed to its own benefit, instead of one global setting for a thousand muscles? The brain stays one; its settings are now each muscle's own (`docs/FORMAL_V5.md`, section 5). A muscle's card (`realms/muscle_cards_v5.csv`) holds what the max uses for it: a machine pool's edge utilisation and window, a battery's line margin and, wired by its power, its hold window and hold margin. The cards were found by an automatic search over every muscle whose settings can change what the max does (`tools/tune_cards.py`), on development seeds only, today's global setting always one of the choices, and kept only where the card beat the global setting beyond the noise on seeds 7100-7109 and again on seeds 7200-7209 and never behind native on any of their seeds under any load (never over its line more often, never less work, never its line cleared later): 364 muscles (333 machine pools, 31 batteries); every other muscle runs the global setting. Inside a body, a battery wired by its power keeps the body's margins on its line (V14: its card was chosen alone; the line carries the whole body's swing). In development, 360 organism runs on the two sets: 0 plants with less work or more misses, the misses removed 1.7 times the global setting's. Fingerprint re-declared (digest `5648f2902f1fae68`, 44 files, the cards among them); the preregistered seeds were run again unchanged. Every card is printed in plain words in the muscle catalog (`docs/MUSCLE_CATALOG.md`).

Amendment 5, 13 October (evening): every muscle from 1 up to one click under its own capacity, read live. The founder's order of 13 October: "you can write it in code ... to show one, two, whatever a muscle's capacity is able to handle, guardrailed and skimmed on its border, one click down probably, so it never goes beyond. And, of course, can all scale right back down. It can never go be less than one." No top or floor in the live controllers is a number written down for a muscle any more; each muscle reads its own from the system it runs on:

- **Machines** (the Kubernetes controller): the top is the operator's own `--max-nodes` where given; else every ready worker plus what the cluster's own autoscaler may still add (its published status); where Omni-Compass resizes the pool with the operator's own command and no autoscaler reports, there is no top but the one the pool shows: one under the first count it refuses, read from the command's own refusal.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Before: a fixed 1,000. The floor stays the founder's two machines, and cruise climbs toward the top one step a decision.

- **Replicas** (the replica room): at the autoscaler's cap with the compass pressing, the cap rises to the replicas the autoscaler's own arithmetic asks for, never past what the machines can hold of the service's pods, one pod under it, read live (the allocatable CPU of every ready worker and of the machines the system can still add, less what every other pod asks for); where every node is a container on one machine (kind), each reports the whole machine's CPU as its own, so that machine's CPU counts once (on 4 October the room raised to 30 on kind served no more requests and ran 78% more pods, `results/live/REPLICA_ROOM.md`: the cap was never kind's limit, the machine was); `--replica-ceiling N` is the operator's own; 0 keeps the cap unmoved. Before: off unless the operator gave a number.
- **The power cap at the max is never set under native**: each machine's idle CPU goes to the capped service's pods (one click under the machine: its last 5% is never handed out, and no pod gets less than its operator gave it), and the frequency ceiling and the GPU limit stay at their top. Before: the governor's trim to demand could set the pods' CPU limit and the frequency ceiling as low as 69.5% even at the max (never on the sets with a response-time probe, where the muscle already conveyed). The tune-down trims as before, with no fixed floor: the pod's own request and its use plus headroom (before: a fixed 65%), and the card's own minimum power limit, read live.
- **GPU**: the clock ceiling's floor is the card's own lowest supported clock (before: 35% of the top); one degree under the card's own slowdown temperature reads as full heat where the card reports it (before: a fixed 83 C for every card).
- **Batch**: held work is admitted while load and power stress are under the compass's wall less one cushion (0.95 - 0.05 = 0.90, the nervous system's own admit gate; before: load 0.80).
- **The nervous system's site power envelope** is the living band of the device's own range, [0.05, 0.95] (before: [0.65, 0.95]); the C++ twin the same, re-proven equal value for value and re-sealed.
- **Words**: the engine's own files say which way a number went (the founder's order of 13 October); the older result label "WORSE" is "AWAY FROM ITS AIM", the GPU benchmark's own.

The modelled organisms are unchanged: their code differs only in comments, file headers and that one label's name, so the 1,107 muscles, the cards and the max give the same numbers on the same seeds. The test rig with the real cluster inside changes beside the engine (protocol 3, `docs/K8S_COMPASS_PREREGISTRATION.md`): the model of the organism on the runner's last core and the kind nodes on the others, and the window set from the heavier arm's measured step. Fingerprint re-declared (digest `6093b2b88aa911b9`, 44 files); the mechanism identity's actuator part re-recorded (the core, the law, the observation map, the governor, the time step and the shield unchanged); every result runs again on it.

88.1.3 The no-harm proof (modelled, class S)

On a fixed seed, for **every** muscle in the catalog, the v5 default does no less work than native, is over its line no more often, and hands every knob back to native on the kill (the dead-man lease); the energy it takes is power given, shown beside the work and the speed it bought. On the preregistered seeds 3000-3009 (commit `eea291501848`, digest `5648f2902f1fae68`, every muscle its own card): **0 of 1,107 muscles LOSS or power given or mixed** (527 toward their aims, 421 at their limit on native, 159 the same), every organism ahead of native under all three loads, and **not one plant with less work or more misses inside any organism under any load**; the misses fall 1.9% to 7.5% under each organism's own load, 1.4% to 7.2% under the climb and 1.1% to 8.3% with work waiting in line, against 1.6% to 6.4%, 0.9% to 3.5% and 1.0% to 7.2% with one global setting (digest `9be48445438943c2`), with less power given and less wear. This is checked in `tests/test_compass_arm_v5.py` and run in full by `tools/run_realms_v5.py` (`results/realms_v5/`). Models are class S: a model's energy is not a meter's, and a plant written by the same people who wrote the law is not an independent test.

88.1.4 In development

While v5 is in active development its fingerprint is **re-declared on each engine change** (`python3 tools/omni_version.py --write v5`), and **no v5 result is published** until the v5 freeze. At the freeze, every benchmark is rerun on v5, A/B/C, the founder hears each result before it goes up, and the fingerprint is final.

88.2 Omni v6: capacity repair and complete non-GPU rerun campaign

Omni v6 stood on main from 15 to 16 October; Omni v7 (`docs/OMNI_V7.md`) stood from 16 to 17 October, and since 17 October the engine that stands is Omni v8 (`docs/OMNI_V8.md`, the founder's order). This page and v6's four three-run tables (`results/live/V6_*.md`) stay as that engine's record, read beside no other engine's.

The engine combines the unchanged v5 muscle law and 1,107-muscle catalog with the v6 shared-host Kubernetes capacity repair. The controller samples Linux host CPU occupancy, counts kind's shared host once, refuses extra replica capacity when that host is busy or unmeasured, and rechecks a previously enlarged replica ceiling. This is a versioned evaluation engine; it does not establish that every workload gains. Every result retains its own engine fingerprint and evidence class.

The source of the capacity repair is branch `codex/v6-kind-headroom-repair`, commit `3bda41a00fab81052551be99e618a523b5c61347`. The damaged Markdown manuals on that branch are not imported. The existing intact manuals remain the starting point. The zero-valued machines-only flag repair is retained: `1` selects machines-only; `0`, empty and unset retain full wiring.

88.2.1 Campaign

`scripts/benchmark_campaign.json` records this request. A successful `verify` run for the release commit marked `[all-nongpu]` starts the grid automatically; an unsuccessful release verification launches no campaign. `scripts/reruns.txt` lists every single-benchmark variant; the grid conductor releases A, B and C gradually alongside every organism at 1, 10, 100 and 1,000 copies and nested 1, 10, 100 and 1,000 runs on free GitHub runners. The v6 dispatch manifest lives under `results/grid_v6`; v5 receipts remain historical. Each job prints its engine fingerprint and source commit. A queued, failed or unavailable test is not a completed measurement.

The queue covers Kubernetes baseline/full/levers/observe, fairness, faults, batch and trace loads, KEDA, CruiseKube, Goldilocks, fixed capacity, scale control-plane checks, both muscle catalogs, all seven organisms (the spine the seventh since 16 October, `docs/THE_SPINE.md`) and their live-cluster grid, Redis, Kafka, PostgreSQL, MySQL, MongoDB, MuJoCo, pandapower, CityLearn, drone swarms, robustness, Linux CPU-governor checks, the Azure full-control burst and the larger Azure organism machine. Linux cpufreq/RAPL execution requires a host that exposes the interfaces; a hosted VM capability refusal remains visible as unavailable hardware.

The Azure burst is `1 4 1 6 1 9`, three paired repetitions, 600 measured seconds per arm, 100 seconds per load stage. Full wiring enables HPA control, pod CPU limits and the existing power model. It does not create host RAPL, clock control or physical power meters on managed Azure VMs.

Free GitHub Kubernetes, Linux, swarm and organism/model workloads may use 1,000 copies and 1,000 runs. Paid cloud and GPU organism scales remain 1, 10 and 100, with at most 100 repetitions. The conductor lists cells that exceed free runner memory/time as pending runner capacity; it never rents a cloud machine for them. The 1,000-copy planning estimates are extrapolations, not completed measurements.

88.2.2 Prepared, not launched

Google/GKE and Amazon/EKS retain their deployment scripts and use the new shared engine on a future manual launch. Their workflows, cloud-organism, gpu-bench and lambda-gpu are excluded from this campaign. No GPU machine is rented by it. `scripts/gpu_campaign_profiles.json` defines one physical card and eight physical cards, with all seven organisms at scales 1, 10 and 100 and 100 paired repetitions per scale. Reports show nested 1/10/100 run prefixes. These are model copies around real hardware; only these three organism scales are permitted.

The profiles are operational through the existing `HIL_SCALES` and `HIL_REPS_BY_SCALE` environment variables. Existing wall-clock budgets still apply: a stage that cannot finish within its budget must be reported incomplete.

88.3 Omni v7: tighter convergence on top of v6 (the engine of 16 to 17 October)

Omni v7 stood on main from 16 to 17 October; on 17 October it was followed by Omni v8 (`docs/OMNI_V8.md`, the founder's order), omni-v7 with one wire changed (the CityLearn runner: a battery whose building simulates outages stays native), and the same day by Omni v9 (`docs/OMNI_V9.md`), and on 18 October by Omni v10 (`docs/OMNI_V10.md`), the engine that stands. This page and v7's twenty-two three-run tables (`results/live/V7_*.md`) stay as that engine's record, read beside no other engine's.

Omni v7 was the engine that stood on main from 16 October (the founder's order: everything on the newest engine). Every benchmark ran again on it (`scripts/reruns.txt`; the grid conductor's reruns, grid and Azure queues restarted on it the same day), and every earlier table stands as its own engine's result until its three runs on v7 land; results from two versions are never pooled. v7 is v6 with five changes, each found from a v6 run's own files or from the governing rules themselves:

#	Change	Where	What it tightens
1	CPU conveyance obeys the namespace quota	`omni_controller/quota.py`, `muscles.py`	no write Kubernetes would refuse
2	On a shared host, no limit raised while the machine is at or over 75% busy or unread (the replica room's guard)	`omni_controller/muscles.py`	the host's top, nothing else
3	The verdict reads a trial in the reports' own words (GAIN, STEADY, LOSS)	`omnicompass/verdict.py`	the do-no-harm trigger
4	Every rule counts in seconds, not decisions	`omni_controller/controller.py`	the same behaviour at any decision period
5	The cloud's rule in one word, `--give-back-only`	`omni_controller/controller.py`, `deploy/install/omni-compass-cloud.yaml`, `scripts/kind_bench.sh`	the bill can only fall or stay

88.3.1 Quota-aware conveyance

The original capacity run 38722001872 tried to raise a pod CPU limit while its namespace CPU quota was already full. The candidate reads each namespace's ResourceQuota CPU-limit hard/used values, obeys the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

stricter pending spec/status ceiling, and reserves each accepted increase across all target deployments in one conveyance pass. It does not increase or delete an operator quota. PriorityClass scope selectors are matched from pod metadata, without deployment or quota names hardwired into the governor. Unknown quota state, read failures and unsupported scopes preserve native limits for expansion; reductions remain possible. Decreases do not create spendable headroom until observed by Kubernetes.

What the first live trial found, and the correction (16 October). The three trials of the candidate as first pushed (Goldilocks run 38825214203, the KEDA add-ons run 38825211370, the capacity test run 38825208939; one run of ten pairs each, so single runs, not three-run tables) read the candidate well short of omni-v6's three-run tables on the two add-on tests: Goldilocks response time at the 95th percentile -6% (STEADY) against v6's -58% GAIN in all three runs, HPA replicas +20% and pods started +200% (power given), the pod start wait +172% (LOSS); KEDA on the requests in flight p95 -2.7% (STEADY) against v6's -73%, replicas +17% (power given); KEDA on the CPU target and the requests p95 +3% (STEADY) against v6's -55%; the capacity test STEADY at every cap, as on v5. The governor wrote 5 commands a run against v6's 15 and the host was 4% busier against 40%: conveyance never raised a limit. The audit says why, 65 times in one repetition: `quota: CPU limit expansion blocked, reason: quota read unavailable: CalledProcessError`. The governor's role on every kind test (`deploy/kind/rbac-omni.yaml`, receipted in each run's `rbac_omni.txt`) cannot list ResourceQuotas, and the budget as first written read an unreadable quota as a zero allowance. The model gate had not seen it because its model of the cluster answered the quota read with an empty list. The correction: a namespace whose quotas cannot be read is **no budget known**, not a zero budget; the raise proceeds as it did on omni-v6 and Kubernetes' own admission, which refuses any write over a quota the governor cannot see, stays the authority (the plug reads every write back and a refused one is audited and never advertised); the audit says so once a pass. Where the role can read the quota, the budget bounds every raise as before. The model now runs the convey model a second time with the quota unreadable (section 88.3.6), the regression `test_an_unreadable_quota_holds_nothing` holds the v6 arithmetic under a forbidden read, and the three trials run again on the corrected candidate; the first trials stay in `results/live/raw/` on this branch as the record of the fault.

Kubernetes admission remains authoritative. A concurrent rejected write is audited and does not become an invented conveyance gain. The node's existing CPU cushion, operator CPU floor, security hold, workload schedule and benchmark validity checks remain intact. The separate runner shutdown in the historical run has no established cause and is not claimed fixed by this actuator change.

88.3.2 Conveyance on a shared host: one guard, two designs refused by the model

The v6 three-run KEDA table (`results/live/V6_KEDA_REQUESTS.md`) read the pod start wait, mean, +12.5%, +12.0% and +22.7% (STEADY on the three-run rule, LOSS in two single runs) beside response time -59% and CPU used +55%. The run's own files (`results/live/raw/addons-run-38725705826`): 149 raises, each pod's limit set to 1,850m (two serving pods on its node) or 3,700m (one), the HPA at 8.8 replicas on average, the host 0.27 busy under native and 0.34 under Omni-Compass, past 75% busy for 0.3% of its samples. On kind every node is a container on one 4-core machine and reports all four cores as its own,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

so the limits sum to about three machines: a ceiling, not a use; the kernel's fair scheduler arbitrates when the pods ask for more than the machine, as it does for native's pods.

Two repairs were written first and both were refused by the model gate (section 88.3.6) before any real run: **the host's CPU counted once** and shared by every serving pod (at the run's nine replicas 3,500m / 9 is under the operator's 500m, so nothing is ever conveyed: in the model the +64% work and -53% response time of conveyance are lost whole, requests served -16% against v6, LOSS); and **a hold while a pod starts on the host** (start wait 1.1% shorter for requests served -0.11% and response time +0.5%, both LOSS against v6 at the real regime). v7 keeps the one guard the model reads as no LOSS, the same as the replica room's (`omni_controller/capacity.py`): on a shared host no limit is raised while the machine's measured busy share is at or over 75% or cannot be read; limits already given stay; lowering is never held back; each hold is written to the audit (`"convey": "held"`). The slower pod start is the busier host serving more requests, the price of the work; it stays shown in every receipt and is judged as the table judges it.

88.3.3 The verdict in words

The verdict (`omnicompass/verdict.py`) is the engine's do-no-harm trigger: before a knob may move one step further from native, the step runs as a trial and its cost per piece of work is compared with the cost at the reference. Through v6 the comparison was the two medians alone: the step was allowed if m[trial] ≤ m[ref] · (1 + tolerance). On noisy work a median wanders, so a step that truly cost more than the allowance was often allowed by chance.

v7 (`judge="interval"`, the default) reads the trial exactly as a report reads a row (`tools/readings.py`). On the logarithm of each piece of work's cost, so that a heavy tail does not decide it, the change is

d = mean ln c[trial] − mean ln c[ref], with the 95% interval d ± 1.96 · √(s²[ref] / n[ref] + s²[trial] / n[trial]) (Welch's standard error),

and with τ = ln(1 + tolerance) the allowance in the same units:

- the interval wholly above zero is a **LOSS**: the step is refused and undone, whatever the allowance says;
- wholly below zero is a **GAIN**; across zero is **STEADY**;
- while the interval's half-width exceeds τ, the evidence is wider than the allowance, and the trial measures on, up to three times `min_samples`, before it decides;
- a GAIN or STEADY step is allowed only if both estimates are inside the allowance: the median (v6's guard, kept) and d ≤ τ;
- a stepwise knob is read the same way against the costs first measured at native as well, so a run of small steps cannot add up past the allowance.

Every judgement writes its reading and its intervals to the audit (`"reading"`, `"interval_ln"`). `judge="median"` reproduces v6 exactly.

On noisy work (log-normal costs, σ = 0.25, a 2% allowance, 300 trials each, seeded):

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

True cost of the step	Allowed through v6 (medians)	Allowed in v7 (in words)
+0% (free)	63%	60%
+1%	56%	50%
+2% (at the allowance)	47%	39%
+3%	40%	28%
+5%	26%	14%

A step that costs more than the allowance is allowed about a third less often at +3% and about half as often at +5%; a free step is kept almost as often. A step whose cost is clearly higher reads LOSS and is refused. These are properties of the rule on modelled costs (class S), not benchmark results (`tests/test_verdict_interval.py`).

88.3.4 Every rule counts in seconds

Five of the governor's rules counted decisions: the clear time after a breach (3), the cruise wait (2), the strict window (5), the verdict's probe spacing (10), recheck (120) and trial length (20). At a decision every 60 seconds those are 3, 2, 5, 10, 120 and 20 minutes; at 15 seconds they would silently shrink fourfold, and a give-back trial's 20 decisions would last 5 minutes instead of 20. v7 states each rule in seconds (`--slo-clear-s 180`, `--cruise-after-s 120`, `--strict-window-s 300`, `--verdict-every-s 600`, `--verdict-recheck-s 7200`, `--verdict-trial-s 1200`) and converts it to decisions at the running period, n = max(1, round(seconds / period)). At 60 s every count is v6's; an explicit count (`--slo-clear`, `--cruise-after`, `--strict-window`, `--verdict-every`, `--verdict-recheck`) still wins.

Two moves are made rates in time as well: the compass moves the HPA target by the same amount a minute at any period (its step is scaled by period / 60, and coasting likewise), and a node pool gives back at most one machine a minute (`RELEASE_PERIOD_S = 60`), however often the governor decides.

88.3.5 The cloud's rule in one word

In a cloud Omni-Compass shows one thing: the same work as native for a smaller bill, never a bigger one. Through v6 that rule was assembled from several settings in the workflow (`OMNI_MACHINES_ONLY=1`, the dial at the tune-down, the sensed and capped deployments left empty). v7 makes it one flag, enforced in the governor itself: `--give-back-only` turns off every pod-, processor-, power-, clock-, cooling- and batch-actuator, sets the replica ceiling to 0 and the dial to the tune-down, and leaves the node pool as the only knob. Whatever else is passed, the governor can then only park a machine the cloud already made, after its own trial, and wake it on a breach: no more pods and no more machines than native. The Azure, Google and Amazon install file (`deploy/install/omni-compass-cloud.yaml`) and the machines-only branch of `scripts/kind_bench.sh` pass it.

88.3.6 The model gate: every change run in our own models first

The founder's order of 15 October, night: every fix, knob and rule is tried in a model before it is pushed, and goes to a real run only where it shows promise there. `tools/model_gate.py` runs two checkouts, the engine that stands and the candidate, each in its own process, on the same seeds, and reads the candidate against the standing engine paired by seed (the mean change, its 95% interval over the seeds, the word by the gauge's aim). Three models, all evidence class S, our own models, never a benchmark result:

- **cluster**: the shipped Kubernetes controller in the cloud setting (node-pool mode, the compass law, the tune-down, `--give-back-only`) on the model cluster of `pilot/selfpilot.py` as the cloud meets it (the cloud's own autoscaler makes machines in both arms; the governor only parks one that exists, which the cloud deletes after ten minutes empty, and wakes it while it exists); a decision every 60 s and the fast check every 15 s; **cluster15** the same with a decision every 15 s.
- **convey**: one 4-core host carrying three kind nodes, php-apache under its HPA (200m request, 500m limit, 50%, 1 to 10), load generators stepping 1 2 3 1 2 1 as `deploy/kind/loadgen.yaml` runs them, set so the native arm sits where the v6 KEDA run's native arm did (host busy 0.28 and p95 0.40, response p95 229 ms, 8.3 pods against the run's 0.27, 0.42, 248 ms and 8.8); the candidate's own `Muscles.convey` called every 15 s. Since 16 October the model runs twice: once with the namespace's quota readable and empty (`convey`), once with the quota unreadable, as the governor's role finds it on every kind test (`convey_unreadable_quota`): the first trial's fault (section 88.3.1) is now the model's to catch.
- **verdict**: the do-no-harm trigger alone on noisy work.

What it read on v7 against v6, 10 seeds (`results/model_gate/`):

Model	Reading
cluster, 60 s	v7 and v6 STEADY on every gauge; both against native: bill -1% (STEADY), energy per core-hour -2.4% GAIN, pods waiting for a place about three times native's (v6 LOSS, v7 STEADY). The cloud setting itself barely cuts the bill in this model and makes pods wait; checked against the Azure receipts' own pending-pod gauge before anything is concluded.
cluster, 15 s	v6: bill +43% (power given), pods waiting 10x (LOSS). v7: bill STEADY against native, pods waiting +111% LOSS, p95 +0.3% LOSS. Every rule now keeps its time, and faster is still not free: the default stays 60 s.
convey	v7 as first written (host once, start hold): requests served -16%, p95 +155% against v6, LOSS, nothing conveyed. The busy guard alone: identical to v6 at the real regime and at double load (the hold never binds under 75%).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Model	Reading
convey, quota unreadable (added 16 October)	the candidate as first pushed (digest 1a0d1d1b91bc49ad): requests served -39% and p95 +113% against v6, LOSS, the host and the limits given identical to native: nothing conveyed, as the live trials found. The corrected candidate (digest d6d467b824c585f1): identical to v6 on every gauge (+64% requests and -53% p95 against native), with the quota readable and empty and with it unreadable alike.
verdict	a step costing 3% more allowed 28% of the time instead of 40%; 5% more, 14% instead of 26%; a free step 60% instead of 63%.

88.3.7 The first three-run tables on v7 (16 October)

Twelve runs on real Kubernetes, ten pairs each, every one omni-v7 (`results/live/V7_*.md`), native against Omni-Compass on top. No row reads LOSS on the three-run rule.

Benchmark	What moved, GAIN in all three of our runs	STEADY	Power given
Goldilocks and the VPA's recommender	response time −45% to −47% mean, −60% to −62% p95, −67% to −69% p99; time over the line −100%	machines, failed requests, replicas, pods started, pod start wait, alert minutes	parked-worker energy +1.6% to +2.3%
KEDA's HTTP add-on	response time −57% to −58% mean, −71% to −75% p95; alert minutes −93% to −96%; replicas −15% to −19%; pods started −17% to −23%	machines, failed requests, pod start wait	parked-worker energy +2.2% to +2.3%
KEDA on CPU and requests	response time −36% to −38% mean, −52% to −54% p95, −57% to −59% p99; time over the line −98% to −100%	machines, failed requests, replicas, alert minutes	parked-worker energy +1.1% to +1.7%
CruiseKube applying its own recommendations	nothing: no setting written	every gauge	none
Fixed capacity, four CPU caps	nothing: the cap blocks the one lever	completed work and work inside the line at every cap	none

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Single runs clear of the noise that the other two did not repeat, each STEADY on the rule: CruiseKube's 99th percentile +3.1% (run A) and node-hours +1.0% (run B); Goldilocks replicas +3.4% (run C); capacity's completed work +3.8% at 1 core (run A).

88.3.8 The room search (16 October): the muscles that read the same as native

The founder's standing question is whether every muscle runs at its own edge. On the realms table of the engine that stands (`results/realms_v5/MUSCLES_V5.csv`, the preregistered seeds 3000-3009), 159 of the 1,107 muscles read SAME AS NATIVE on every load. Measured muscle by muscle on development seeds (7100 and 7101) in our own models (class S, never a benchmark result):

Muscles	Plant and knob	What the max does	Native's own misses	Room under the max's gauges
111	a process loop's setpoint (the process, irrigation, turbine, batch-reactor, pipeline, mill, district-heat and inverter presets)	writes nothing: the loop's actuator is native's full range, and the loop's work is the disturbance it handles, fixed by the load	median 0.00% of decisions, at most 0.56%; 6 of the 111 miss at all	none on work or speed; on misses, the 0.56% of six loops, which a setpoint eased toward the band's middle could touch: a card candidate for a later version, worth under one part in a hundred
36	a cooled zone's setpoint (the data-hall, building and hospital presets)	cools ahead of the heat (28 of the 36 wrote), and under native the room never nears its line either	0.00% on all 36	none: nothing above native to give
Muscles	**Plant and knob**	**What the max does**	**Native's own misses**	**Room under the max's gauges**
12	a battery's power knob (the UPS, microgrid and facility presets)	holds the charge for the line and gives native's full power once the line could need it	2.1% to 24.3% of decisions	every miss falls while the charge sits at the operator's reserve (0.6 for a UPS, 0.2 for a microgrid), above the outage floor; the power knob may not spend the reserve, and the max keeps that boundary. The charge between the reserve and the floor

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Muscles	Plant and knob	What the max does	Native's own misses	Room under the max's gauges
				belongs to the setpoint knob, where the engine's cards already read GAIN (8 of 8)

The reading: the max already takes every muscle to the edge its own knob has. Where a muscle reads the same as native, the measurement says there is nothing above native for that knob to give, and the max leaves it native by design (do no harm). The one measurable room, six process loops' 0.56% of decisions, is noted for a later version's card search; it is not an engine change, and no engine file moved for this measurement.

88.3.9 Validation

Six shared-host regressions pass (`tests/test_convey_shared_host.py`: each node keeps its own arithmetic under the top, a busy or unread host holds every raise, a busy host still lowers, a start holds nothing, separate machines are never held, an unreadable quota holds nothing). Nine quota regressions pass (`tests/test_quota_convey.py`, among them: an unreadable quota is no budget known); the original source fails both the full-quota regression and the admission-rejection regression. Existing conveyance integration checks pass unchanged. The verdict's rule tests (`tests/test_verdict_interval.py`, `tests/test_verdict.py`: v6's medians kept under `judge="median"`, a noiseless 1.5% rise refused against a 1% allowance under v7), the time-correct tests (`tests/test_time_correct.py`, `tests/test_cloud_cadence.py`) and the cloud tests (tests/test_cloud_machines_only.py (removed on 31 October, when the founder struck the cloud's rule)) pass, as do every verdict user's tests (Redis, Kafka, pgbench, sysbench, YCSB, CPU power, GPU). Live GitHub trials on the v7 commit (KEDA's add-ons, Goldilocks, CruiseKube, capacity) repeats the original cap 1500m / repetition 4 / 1200-second-per-arm case at the original request rates. Its completion and measured result must be read from its artifact, with any LOSS retained. The trial cannot launch Azure, Google, Amazon or GPUs.

The organisms the candidate is run on are the seven of 16 October (the spine, the 267 muscles every stack runs on, the seventh; `docs/THE_SPINE.md`): they are groupings of catalog rows made in the runners, so the candidate's fingerprint did not move for them, and every organism table on this engine lists the spine first.

Reference: Kubernetes Resource Quotas and in-place container resource resizing. The CPU budget helper is included in both the engine and actuator fingerprints. README.md, LICENSE, NOTICE, DISCLOSURES.md, PATENTS.md and TRADEMARKS.md accompany the trial artifact.

88.4 Omni v8: the battery that carries its building through an outage stays native (the engine of 17 October)

Omni v8 stood on main on 17 October; later that day it was followed by Omni v9 (`docs/OMNI_V9.md`), omni-v8 with the CityLearn battery wire reading the coming hour, which cuts the one row this page names (section 88.3.3; printed LOSS, power given by the key, `docs/OMNI_V9.md`, section 1), and on 18 October by Omni v10 (`docs/OMNI_V10.md`), the engine that stands. This page stays as omni-v8's record, read beside no other engine's.

Omni v8 was the engine that stood on main from 17 October (the founder's order: "there's a new version 8 ... push in all and update all"). It is omni-v7 (`docs/OMNI_V7.md`) with one change to one wire, made because a three-run table of omni-v7 read LOSS and the cause was found to be ours. Its fingerprint is `OMNI_V8.json` (digest `f93d233136a1f902`, 46 files); of those 46 files, 45 are omni-v7's bytes, and the one that differs is the CityLearn runner. Every benchmark runs again on it (`scripts/reruns.txt`; the conductor's reruns, grid and Azure queues restarted on it the same day), and every omni-v7 table stands as omni-v7's result until its three runs on v8 land; results from two versions are never pooled. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

#	Change	Where	What it tightens
1	A battery whose building simulates power outages stays native: Omni-Compass moves only the batteries with no second duty	`tools/run_citylearn.py`	do no harm where the battery's charge is also its building's reserve

88.4.1 What omni-v7 read, and why

The omni-v7 CityLearn table (`results/live/V7_CITYLEARN.md`; runs 38937540021, 38949618073, 38959444615) read GAIN in all three of our runs on the electricity bought and the daily peak in all ten battery districts, and **LOSS in all three of our runs in the seven 2023 districts** on the energy not served (+2.0% to +9.8%) and the time uncomfortable (+0.01% to +0.15%), beside the ramping +4.5% to +6.2%, the highest peak +2.5% (three districts) and the monthly unevenness +0.07% (one), power held and so power given by the key (the table printed those three LOSS too, until the CityLearn tool was corrected on 17 October).

The cause was found on CityLearn itself (version 3.0.2, the version the runs installed), run locally on the same district files and reproducing the omni-v7 numbers of `citylearn_challenge_2023_phase_2_local_evaluation` to the last digit:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- The seven 2023 districts are the only districts CityLearn ships whose buildings simulate power outages (every building in each: 3, 3, 3, 3, 6, 6 and 6; every other district none, read from each district's own `schema.json`). CityLearn counts the energy not served only in outage hours (`citylearn/cost_function.py`, `normalized_unserved_energy`), and the time uncomfortable rises when an islanded building cannot run its cooling.
- The battery wire read the district's draw alone. It did not see the outage hours, and it did not see that in these buildings the battery has a second duty: carrying the building through the outage. A command that moves the battery for the district's draw during an outage asks for energy the islanded building cannot have.
- Three narrower repairs were tried on the tuning district first and refused there: charging only (the energy not served unchanged at +5.96%, LOSS, the ramping +3.5%); handing the battery back to native only during outage hours (the energy not served −2.7% and the discomfort −0.13%, both GAIN, with the ramping +7.0% and the monthly unevenness +0.06% beside them); and moving no more energy than the draw's excess over its band (the daily peak +0.5% and the ramping +2.6%). With peaks, swings and unevenness then read as misses, each was refused. By the key (17 October) those rises are power given, so the second, native only in outage hours, reads GAIN on both misses; it is studied again for the next engine version.

88.4.2 The change

The wire now leaves native every battery whose building simulates power outages (CityLearn's own `simulate_power_outage`, read from the building), as a water tank was left native in round 2: a battery that is also its building's reserve is a muscle with a second duty, which needs its own wire and its own reading (the outage risk) before Omni-Compass moves it. Every other battery is moved exactly as before: the compass law, its gain, its response, its glide, its band and its hand-back are unchanged. An action list the wire cannot place on its buildings moves nothing. The hour count of the file counts only hours where a command moved, and each district's file says how many batteries were left native for outages (`batteries_left_native_for_outages`).

88.4.3 What it does, read on CityLearn before any GitHub run

On the seven 2023 districts the omni arm is native's to the last digit (every battery left native; checked on `citylearn_challenge_2023_phase_2_local_evaluation` and `citylearn_challenge_2023_phase_3_1`). On every district without outage buildings the wire's commands are the same bytes as omni-v7's, so their results are omni-v7's (checked to the digit on `citylearn_challenge_2022_phase_all_robustness`, every gauge of both arms identical to omni-v7's GitHub run 38937540021, no battery left native). So v8 removes every LOSS of the 2023 districts and, with them, their small GAINs (the electricity bought −0.1% to −0.3%, the daily peak −1.3% to −2.6%), which were bought with the LOSS beside them.

One row the table printed LOSS remains, and it is said here: in `citylearn_challenge_2022_phase_all_robustness` (no outage buildings) the monthly

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

unevenness rose 0.11% in all three of our runs (power given by the key: a ratio of the power held), beside the bill −8.6%, the electricity bought −14.7%, carbon −11.9%, the daily peak −14.0% and the highest peak −2.7%, all GAIN. The score is a ratio (one minus each month's mean over its peak), and it rose because the energy fell faster than each month's top hours, which sit at the batteries' limit. Its repair is looked into on its own, in the model gate first; v8 does not change it.

88.4.4 The model gate and the trial

The change touches no Kubernetes, card or cloud controller, so the model gate's models (`tools/model_gate.py`) read the same on both checkouts by construction; the gate was run all the same, omni-v8 against omni-v7 on the same seeds, and is recorded in `results/model_gate/V8_VS_V7.md`: seeds 1 to 8, a day each, every gauge of every model (the cluster at 60 s and at 15 s, conveyance with the quota readable and unreadable, the verdict on noisy work) identical between omni-v8 and omni-v7, to the last digit and in every count (steps allowed and refused, trials abandoned, machines parked, errors). The models' readings against native are omni-v7's and stay disclosed in `docs/OMNI_V7.md`, section 6 (at a decision every 15 s the cloud setting makes pods wait longer than native, which is why the decision period stays 60 s). These are our own models (class S), never a benchmark result.

The trial is the CityLearn benchmark itself, A, B and C on the v8 commit, read by `tools/citylearn_abc.py` into results/live/V8_CITYLEARN.md when they land: it must read no LOSS in the 2023 districts and the same table as omni-v7 everywhere else. The disclosure every amendment carries: every CityLearn district has now been seen, so no untouched district remains for this amendment; it was fixed on one district (`citylearn_challenge_2023_phase_2_local_evaluation`) and is reported on all (`docs/CITYLEARN_PREREGISTRATION.md`, amendment of 17 October).

88.4.5 What runs again on it

Everything, A, B and C, from the moment it landed (`scripts/reruns.txt`, released by the conductor a few a tick: A of every benchmark, then B, then C); the grid on its own manifest (`results/grid_v8/`); every Azure set from A again (`scripts/azure_queue.txt`). The omni-v7 runs already started run to their end (nothing is cancelled) and stay as omni-v7's record. Google Cloud and Amazon carry the same sets behind their switches, off until the founder turns them on; the GPU runs on Lambda wait for his word and one exact commit. The organisms are the seven of 16 October, the spine first (`docs/THE_SPINE.md`).

88.5 Omni v9: the battery wire reads the coming hour (the engine that stood on 17 and 18 October)

Omni v9 stood on main from 17 to 18 October; on 18 October it was followed by Omni v10 (`docs/OMNI_V10.md`), the engine that stands: omni-v9 with the battery glide at 0.0875 an hour, the speed that cuts the bill most with no LOSS (section 88.3.2 below gives the ladder it was chosen from). This page stays as omni-v9's record, read beside no other engine's.

Omni v9 was the engine on main from 17 October (the founder's orders: "we're going into another version of Engine ... Apply the fix, run it, and see in the model sim that it works"; "Omni-Compass should be tuned to exploit all that can be and keep all healthy and never raise its bill ... the tuning stays where it doesn't ever hurt anyone"). It is omni-v8 (`docs/OMNI_V8.md`) with one wire repaired and one statistical table made exact. It was written for one omni-v8 row the table printed as LOSS; on 17 October the founder found that word misapplied (section 88.3.1): the row was power given. The repair it led to stands on its own, because it cuts the bill further in every district. Its fingerprint is `OMNI_V9.json` (digest `7379f3a79ff2c475`, 47 files); 44 are omni-v8's bytes, two differ (the CityLearn runner and the realms harness) and one is new (`omnicompass/student_t.py`). It was proven in our own runs of CityLearn and in the model gate before it was pushed. Every benchmark runs again on it, and every earlier table stands as its own engine's result until its three runs on v9 land; results from two versions are never pooled. Run and scored by The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

#	Change	Where	What it tightens
1	The battery wire reads the coming hour's draw (the mean of the same hour over the past seven days, only hours already seen) and its adjustment glides at up to 0.0625 of the command's range an hour (0.05 before), the fastest glide that read no LOSS on any score in any district	`tools/run_citylearn.py`	the battery answers the hour it moves, not the hour gone
2	Every 95% interval uses the exact Student t quantile for its number of pairs	`omnicompass/student_t.py`, `realms/harness.py` and the table tools	no interval narrower than its sample allows, at any count

88.5.1 What omni-v8 read, and why

One row of the omni-v8 table was printed LOSS: in `citylearn_challenge_2022_phase_all_robustness` (17 buildings, a battery in each, no outage buildings) the monthly load unevenness (`monthly_one_minus_load_factor_average`: one minus

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

each month's mean draw over its peak) rose 0.11% in all three of our runs, beside the bill −8.6%, the electricity bought −14.7%, the daily peak −14.0% and the highest peak −2.7%, all GAIN (the omni-v7 table, whose commands omni-v8 repeats to the byte outside the 2023 districts). **By the key that row is power given, not a LOSS**: the unevenness is the shape of the power the district holds from the grid, a resource held, as a peak is; it is neither time waited nor work done nor a miss. The CityLearn table tool had filed the peaks, the swings and the unevenness as misses; it was corrected on 17 October (`tools/citylearn_abc.py`, `tools/readings.py`: one key for every gauge, as a cluster's peak power always was). Run locally, the same wire also raised, on districts the GitHub benchmark does not run (CityLearn ships them only in its source repository), the tuning district's monthly unevenness +0.26%; in the 2022 phase 2 the highest peak +0.17%, the daily unevenness +1.03% and the monthly unevenness +0.68%; in the 2022 phase 3 the highest peak +0.45% and the ramping +3.37%: power given, every one, and shown here with the rest.

The cause was found in an hour-by-hour trace of the omni-v8 wire on the robustness district (CityLearn 3.0.2, run locally):

- The compass read the district's draw of the hour just gone and moved the batteries for the hour coming, and its adjustment could change by only 0.05 of the command's range an hour. Averaged by hour of day over the year, the adjustment discharged hardest at 00:00 and charged hardest at 15:00, while the district's draw peaked at 19:00 and bottomed at 13:00: it ran about five hours behind the day, still adding charge at 17:00 and 18:00 as the evening peak climbed.
- So the batteries were empty when each month's top hour came: at the month's highest net draw the mean state of charge was 0.000 to 0.037 in ten of the eleven months the trace covers.
- The score is a ratio. Lowering a month's mean (less energy bought) while its peak hour stays at the batteries' limit raises one minus mean over peak: the energy fell faster than the top hours.

Narrower repairs were tried on the robustness district first; each left the unevenness up, so none is in the engine:

Candidate	What it changed	Monthly unevenness against native
no discharge below the band's middle	Omni-Compass adds no discharge in a quiet hour	+0.11% (power given)
no new peak (the month's top so far, and the month's or the week's)	the charge it adds never lifts the district above its top so far	+0.11% (power given)
Candidate	**What it changed**	**Monthly unevenness against native**
peak push	full discharge where the draw nears the month's top so far	+0.12% (power given)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Candidate	What it changed	Monthly unevenness against native
a reserve of 30%, 50% or 70% of charge	its added discharge stops at the reserve	+0.42%, +0.25%, +0.25% (power given), and the highest peak's GAIN lost
the hour gone, glide 0.25	faster only	−0.61% (GAIN), the ramping +13.2% (power given)

88.5.2 The change, and how far it is pushed

The reading is the draw of the hour the batteries are about to move: the mean of the same hour of the day over the past seven days, h[t−24], h[t−48], …, h[t−168] (only hours already seen; before a day has been seen, the last hour's draw). Nothing else in the wire changed: the compass law, its gain (0.5), its response (1 h), its band (the 10th to the 90th percentile of the past week's draw), the hand-back at 90% of the year, the batteries left native in outage buildings (omni-v8) and the water tanks left native.

The glide was set where no score of any district rose: with the new reading, every glide from 0.05 to 0.10 an hour was run on the districts where the edge lies, and the fastest at which nothing rose in either is 0.0625. Read by the key, no glide on the ladder reads a LOSS anywhere: every rise below is power given, and the bill keeps falling up to 0.0875 to 0.10:

District	Score	0.05	0.0625	0.075	0.0875	0.10
phase 2	daily unevenness	+0.25% power given	-0.09% GAIN	-0.67% GAIN	-0.94% GAIN	-0.91% GAIN
phase 2	net-zero shortfall	-7.53% GAIN	-4.77% GAIN	-3.38% GAIN	-2.54% GAIN	-1.99% GAIN
phase 2	the bill	-14.12% GAIN	-17.22% GAIN	-18.75% GAIN	-19.17% GAIN	-19.03% GAIN
phase 3	the ramping	-5.05% GAIN	-1.91% GAIN	+2.32% power given	+6.18% power given	+9.59% power given
phase 3	net-zero shortfall	-2.21% GAIN	-0.76% GAIN	-0.04% STEADY	+0.25% power given	+0.41% power given
phase 3	the bill	-6.60% GAIN	-7.32% GAIN	-8.10% GAIN	-8.43% GAIN	-8.32% GAIN

At 0.05 the 2022 phase 2's daily unevenness rises; from 0.075 the 2022 phase 3's ramping does, and from 0.0875 its net-zero shortfall: power given, each. At 0.0625 every score of every district reads GAIN (section 88.3.3). The founder's rule for the tune (use everything that can be used, keep everything healthy, never raise

All patents, copyrights and trademarks filed in the USA.

the bill) takes the glide past 0.0625, to the speed that cuts the bill most with no LOSS: that is the next version's change, read on CityLearn first.

The second change is statistical and moves no command. The interval tables written in each tool stopped at a few sample sizes and fell back to 1.96 (the normal quantile) for a number of pairs they did not list, too narrow an interval for a small sample. Every tool now takes the exact quantile from one file, `omnicompass/student_t.py` (the regularized incomplete beta function, checked against the published table to three decimals). Every value the old tables held is unchanged; no published table used a count the old tables lacked, so no published reading moves.

88.5.3 What it does, read on CityLearn before any GitHub run

CityLearn 3.0.2, run locally on its own district files, native (CityLearn's BasicRBC) against Omni-Compass on top of it; every score is CityLearn's own (each over no battery at all), and every row is read by the one key. The omni-v8 column is the wire as it stood.

2022 robustness, 17 buildings (where the omni-v8 row stood)

Across the districts above: omni-v8 29 GAIN, 0 STEADY, 7 power given, 0 LOSS (where it was run); omni-v9 58 GAIN, 9 STEADY, 0 power given, 0 LOSS.

The districts: the robustness district, where the omni-v8 row stood and where the cause was found; the tuning district (`citylearn_challenge_2022_phase_1`); the 2022 phases 2, 3 and all (shipped in CityLearn's source repository, not in its package, so the GitHub benchmark does not run them); and the two 100-building neighbourhoods the benchmark counts (Alameda County, Travis County). The seven 2023 districts are unchanged by construction: every battery in them is left native (omni-v8), so their omni arm is native's to the last digit. The shipped runner (`tools/run_citylearn.py`) and the study's copy of it give the same numbers to the last digit on both arms (checked on the robustness district).

Shown, power given. Month by month, the peak hour with Omni-Compass on top rises above native's in some months: in 2 of 12 months in the robustness district, 3 in the tuning district, 1 in each of the 2022 phases 2 and 3, and 2 in phase all (omni-v8: 3, 3, 2 and 4); in Alameda and Travis in none. A peak is power held, so each is power given, beside the bill and the energy it bought; CityLearn's own scores over the year (the highest peak, the daily peak and the monthly unevenness) read GAIN. A guard that keeps Omni-Compass's added charge under the month's top so far cut one of the two months on the robustness district and left every score GAIN; it is a candidate for the next version, in the model gate first.

88.5.4 The model gate

The changes touch no Kubernetes, card or cloud controller, and the model gate's models (`tools/model_gate.py`) do not run the CityLearn wire, so they read the same on both checkouts by construction; the gate was run all the same, the candidate against omni-v8 on seeds 1 to 8, and is recorded in `results/model_gate/V9_VS_V8.md`: every gauge of every model (the cluster at 60 s and at 15 s, conveyance with the quota readable and unreadable, the verdict on noisy work) identical to omni-v8 to the last digit, in every count (it ran with the glide at 0.10, a setting no model reads). The same models show, for omni-v8 and the candidate alike, a pod start wait +9% against native beside 64% more requests served: the same row the real KEDA HTTP run showed (`docs/OMNI_V7.md`, section 6; `docs/STATE_OF_PLAY.md`, Open), the next repair. These are our own models (class S), never a benchmark result.

88.5.5 What runs again on it

Everything, A, B and C, from the moment it lands (`scripts/reruns.txt`, the omni-v9 campaign, released by the conductor a few a tick), with three entries added beside the operator's settings: MySQL, Redis and MongoDB with native exactly as shipped (MySQL's own 128 MB buffer pool; Redis with no memory ceiling and its own `noeviction` rule; MongoDB's own cache, half of the machine's memory less 1 GB). The grid on its own manifest (`results/grid_v9/`); every Azure set from A again. Google Cloud and Amazon stay behind their switches; the GPU runs on Lambda wait for the founder's word and one exact commit. The CityLearn table's three runs on GitHub make the table V9_CITYLEARN.md in `results/live/`; it must read no LOSS in any district, as it did locally.

88.6 Omni v10: the battery glide at the speed that cuts the bill most (the engine that stood on 18 October)

Omni v10 stood on main on 18 October; the same day it was followed by Omni v11 (`docs/OMNI_V11.md`), the engine that stands: omni-v10 with the Kubernetes governor's hold on a reading with no machine in service. This page stays as omni-v10's record, read beside no other engine's. The founder's orders behind it: "Omni-Compass should be tuned to exploit all that can be and keep all healthy and never raise its bill ... whatever one can't be achieved doesn't get achieved. And the tuning stays where it doesn't ever hurt anyone"; and, on 17 October, "a minus doesn't mean a loss and neither does a plus mean a gain if you don't understand what it's against". It is omni-v9 (`docs/OMNI_V9.md`) with one setting changed: the most the CityLearn battery wire's adjustment may change in an hour (the glide) goes from 0.0625 to 0.0875 of the command's range. The CityLearn runner's own receipt now reads every score by the one key, as every table already did.

Its fingerprint is `OMNI_V10.json` (digest `4bf39b0d707784de`, 47 files). Forty-six files are omni-v9's bytes and one differs (the CityLearn runner). The change was proven in our own runs of CityLearn and in the model gate before it was pushed. Every benchmark runs again on it. Every earlier table stands as its own engine's result until its three runs on v10 land, and results from two versions are never pooled. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

#	Change	Where	What it does
1	The battery wire's glide: 0.0875 of the command's range an hour (omni-v9: 0.0625)	`tools/run_citylearn.py`	the batteries follow the coming hour faster, and the bill falls further in every district that has a price

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

#	Change	Where	What it does
2	The runner's receipt reads every score by the one key: a fall is a GAIN; a rise in energy not served or time uncomfortable is a LOSS; a rise in any other score is power given	`tools/run_citylearn.py`	one key for every output, as the three-run table (`tools/citylearn_abc.py`) already read

88.6.1 Why the glide moved

omni-v9 set the glide at the fastest speed at which no score in any district rose. That rule counted a rise in the ramping or in the distance from net zero against the engine. The one key of 17 October (`tools/readings.py`) does not. The ramping, the peaks, the unevenness and the net-zero distance describe the power the district holds from the grid: they are resources held. A rise in one of them is power given, shown beside what it bought, never a LOSS. Only what the occupants miss is a LOSS: energy not served and time uncomfortable.

Read by that key, the ladder omni-v9 ran shows that no glide reads a LOSS anywhere, and that the bill keeps falling up to 0.0875. At 0.10 it falls less in both districts that set the edge:

District	Score	0.05	0.0625 (omni-v9)	0.075	0.0875 (omni-v10)	0.10
phase 2	the bill	-14.12% GAIN	-17.22% GAIN	-18.75% GAIN	-19.17% GAIN	-19.03% GAIN
phase 2	daily unevenness	+0.25% power given	-0.09% GAIN	-0.67% GAIN	-0.94% GAIN	-0.91% GAIN
phase 2	net-zero shortfall	-7.53% GAIN	-4.77% GAIN	-3.38% GAIN	-2.54% GAIN	-1.99% GAIN
phase 3	the bill	-6.60% GAIN	-7.32% GAIN	-8.10% GAIN	-8.43% GAIN	-8.32% GAIN
phase 3	the ramping	-5.05% GAIN	-1.91% GAIN	+2.32% power given	+6.18% power given	+9.59% power given
phase 3	net-zero shortfall	-2.21% GAIN	-0.76% GAIN	-0.04% STEADY	+0.25% power given	+0.41% power given

So 0.0875 is the glide that cuts the bill most with no LOSS: the founder's rule for the tune. Nothing else in the wire changed. The compass law, its gain (0.5), its response (1 h), its reading (the coming hour, from the same hour of the past seven days), its band (the 10th to the 90th percentile of the past week's draw), the hand-back at 90% of the year, the batteries left native in outage buildings and the water tanks left native are all omni-v9's.

Across the districts above: omni-v9 45 GAIN, 0 STEADY, 0 power given, 0 LOSS; omni-v10 43 GAIN, 0 STEADY, 2 power given, 0 LOSS.

Alameda County and Travis County (100 buildings each) were still running locally when this version was pushed; this machine runs each neighbourhood for hours, and their omni-v9 runs read no LOSS (`docs/OMNI_V9.md`, section 3). No score in them that can read a LOSS moves with the glide: they carry no price (the bill is 1.0 in both arms, STEADY by construction), no outage (energy not served is 0 in both arms) and no comfort the electric batteries touch (time uncomfortable +0.00% on omni-v9). Every other score there is a resource spent or held, where a rise is power given. Their three runs on GitHub, with every other district, make the omni-v10 CityLearn table; the local runs are added here when they finish.

What the faster glide trades. In every district with a price, the bill falls 1.1 to 2.4 points further than at omni-v9. Most other scores fall a little less than at omni-v9 and still read GAIN: the electricity bought, the carbon, the daily peak, the ramping, the unevenness and the net-zero distance. The highest peak holds where omni-v9 left it, except in the 2022 phase 2 (−8.30% against −11.26%), and that district's daily unevenness falls further (−0.94% against −0.09%). Two rows of the 2022 phase 3 rose and are power given: the ramping +6.18% and the net-zero shortfall +0.25%. A little more electricity is bought than at omni-v9 while the bill falls further, so each unit bought costs less on average. None of these five districts carries the occupants' own scores (energy not served, time uncomfortable); in the 2023 districts they are native's to the last digit, and in Alameda and Travis they read STEADY on omni-v9.

Shown, power given. In some months the peak hour with Omni-Compass on top rises above native's. With omni-v10 that happens in 3 months in the robustness district (omni-v9: 2), 3 in the tuning district (3), 1 in the 2022 phase 2 (1), 1 in the 2022 phase 3 (1) and 3 in phase all (2). By day it happens on 23, 25, 21, 56 and 23 days of the year (omni-v9: 16, 28, 15, 43 and 16). The two 100-building neighbourhoods were still running locally when this version was pushed (on omni-v9 neither showed a month whose peak rose above native's). A peak is power held, so each of these is power given. CityLearn's own scores over the year (the highest peak, the daily peak and the monthly unevenness) read GAIN in every one of the five districts.

The districts: the robustness district (`citylearn_challenge_2022_phase_all_robustness`); the tuning district (`citylearn_challenge_2022_phase_1`); the 2022 phases 2, 3 and all, which CityLearn ships in its source repository but not in its package, so the GitHub benchmark does not run them; and the two 100-building neighbourhoods the benchmark counts (Alameda County and Travis County). The seven 2023 districts are unchanged by construction. Every battery in them is left native (omni-v8), so their omni arm is native's to the last digit; this was checked with the v10 runner on

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

`citylearn_challenge_2023_phase_2_local_evaluation`, where all eleven scores are identical.

88.6.3 Refused: the outage buildings' batteries outside the outage hours

One more change was tried before this version was set, at the same glide. The batteries in buildings that carry an outage would be steered outside the outage hours and handed back to native through each outage. Six of the seven 2023 districts were run:

2023 district	the bill	energy not served	time uncomfortable
phase 2, local evaluation	+0.19% power given	-2.68% GAIN	-0.12% GAIN
phase 2, online evaluation 1	-0.09% GAIN	**+0.69% LOSS**	-0.04% GAIN
phase 2, online evaluation 2	-0.11% GAIN	-0.15% GAIN	+0.00% STEADY
phase 2, online evaluation 3	-0.09% GAIN	-1.44% GAIN	-0.06% GAIN
phase 3, district 1	-0.25% GAIN	-2.47% GAIN	-0.04% GAIN
phase 3, district 2	-0.37% GAIN	-0.38% GAIN	-0.03% GAIN

In the first online evaluation, more energy went unserved. That is a miss, a LOSS. In the local evaluation, the bill rose. One LOSS is enough to refuse the change, and the founder's rule never raises the bill, so the seventh district was not needed. The batteries in outage buildings stay native all year, as in omni-v8 and omni-v9.

88.6.4 The model gate

The change touches no Kubernetes, card or cloud controller, and the model gate's models (`tools/model_gate.py`) do not run the CityLearn wire, so they read the same on both checkouts by construction. The gate was run all the same, the candidate against omni-v9 on seeds 1 to 8, and is recorded in `results/model_gate/V10_VS_V9.md`. Every gauge of every model reads identical to omni-v9 to the last digit (26 of 26: the cluster at 60 s and at 15 s, and conveyance with the quota readable and unreadable), and so do every count and the verdict on noisy work. These are our own models (class S), never a benchmark result.

88.6.5 What runs again on it

Everything runs again, A, B and C, from the moment v10 lands (`scripts/reruns.txt`, the omni-v10 campaign, released by the conductor a few at a time each tick). The grid runs on its own manifest (`results/grid_v10/`), and every Azure set starts again from A. Google Cloud and Amazon, switched on by the founder on 18 October with their secrets in, run the same four sets from A, one at a time in each machine-family queue. The GPU runs on Lambda wait for the founder's word and one exact commit. The three CityLearn runs on GitHub make the omni-v10 CityLearn table in `results/live/`. It must read no LOSS in any district, as it did locally in every district read before the push.

All patents, copyrights and trademarks filed in the USA.

88.7 Omni v11: a reading with no machine in service is blind, never an overload (the engine that stood 18 to 19 October)

Omni v11 stood on main from 18 to 19 October; on the night of 19 October Omni v12 (`docs/OMNI_V12.md`) took its place, which is omni-v11 with a refused raise held and the swarm's reflex acting at once. This page stays as omni-v11's record, read beside no other engine's; its 23 three-run tables (`results/live/V11_*.md`) are its own. The founder's order behind it: every fault found is fixed, none set aside. It is omni-v10 (`docs/OMNI_V10.md`) with one guard added to the Kubernetes governor. When the cluster's reading shows no machine in service, the governor holds. It records why, decides nothing from that reading, writes nothing, and keeps the last reading that had machines. Every setting, gain, preset and muscle is omni-v10's, and so is every rule but this guard.

Its fingerprint is `OMNI_V11.json` (digest `745aa53ec8eeb67b`, 47 files). Forty-six files are omni-v10's bytes; one differs, the Kubernetes governor (`omni_controller/controller.py`). The change was proven in a unit test that reproduces the fault and in the model gate before it was pushed. Every benchmark runs again on it. Every earlier table stands as its own engine's result until its three runs on v11 land, and results from two versions are never pooled. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

#	Change	Where	What it does
1	A decision whose reading shows no machine in service holds: it is recorded as held, with its reason, and nothing is decided from it or written	`omni_controller/controller.py`, the decision	the engine is never fed a load measured against no capacity; the decision never divides by zero
2	The fast floor check returns at once on the same reading	`omni_controller/controller.py`, the floor check	no machine is added from a blind reading
3	The last reading with machines stays the one the conveyance is bounded by	`omni_controller/controller.py`	a blind moment never lifts the bound on the CPU each pod may be given

88.7.1 The fault, found in a real run

In the omni-v10 CruiseKube test (run 39120444653, repetition 8, the arm with Omni-Compass on top), every worker of the kind cluster left service for two minutes. All six workers sit as containers on one GitHub runner. Eight of the capture's readings show no machine in service, while the service answered every one of its probes (no failed request in any minute of the window). In that reading the machines' capacity was zero. omni-v10's governor fed the engine a load measured against that zero capacity, read as the highest overload its scale allows (a load ratio of 2). It then divided by the capacity when it computed the machine floor. Two of its

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

fifteen decisions and one floor check ended in a division by zero. Each wrote nothing, as the audit shows, and the cluster kept the settings it had. But the engine's own state had been given a false overload. The words of the rig named neither: they said the governor was not running.

omni-v11 reads such a reading as blind. The engine is not stepped, the floor is not computed and no machine is added. The audit says "held: the cluster's reading shows no machine in service; nothing decided, nothing written". When the machines return, the next decision reads them and the governor takes up where it was. `tests/test_blind_reading.py` builds the same cluster: two workers serving, then both out of service in the reading. On omni-v10 both of its tests end in the division by zero; on omni-v11 both pass, with no write and no error.

The rig was repaired beside it (no engine file; `docs/K8S_COMPASS_PREREGISTRATION.md`, amendment of 18 October). A window whose capture shows no machine in service is refused in either arm, because its machine count is wrong. A failed decision is named by its error. The capture records each node's taints and conditions at the moment it sees no machine in service.

88.7.2 The model gate

The candidate was run against omni-v10 on seeds 1 to 8 in our own models (`tools/model_gate.py`; `results/model_gate/V11_VS_V10.md`), on every model: the cluster at a decision every 60 s and every 15 s, the new blink model, conveyance with the quota readable and unreadable, and the verdict on noisy work. This is the first gate in which each arm is proven to import its own checkout's engine. From omni-v9's gate on, the gate had put its own tree first, so both arms ran the candidate; omni-v9 and omni-v10 changed no file a model runs, so their readings hold by construction, and each page carries the correction.

Model	Gauges identical to omni-v10	Decisions that failed (omni-v10 / omni-v11)	Decisions held (omni-v10 / omni-v11)
the cluster, a decision every 60 s	6 of 6	0 / 0	0 / 0
the cluster, a decision every 15 s	6 of 6	0 / 0	0 / 0
the blink: every machine out of service in the reading for 2 minutes every 6 hours	6 of 6	64 / 0	0 / 64
conveyance, the quota readable	8 of 8	(no decision of the governor)	
conveyance, the quota unreadable	8 of 8	(no decision of the governor)	
the verdict on noisy work	5 of 5	(no decision of the governor)	

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Every gauge and every count is identical. A decision that failed and one that held both write nothing, so nothing the models measure moves; what moves is the record (a reason where there was an error) and the engine's own state, which a blind reading no longer reaches. Against native, the two engines read the same, and four rows read LOSS in both: the pod start wait under conveyance (+9.0% mean, +10.0% at the 95th percentile), the pending-pod minutes and the response time at a decision every 15 s (+111.7%, +0.33%; no run decides that often), and the alert minutes in the blink model (+2.35%). They are not this change's; they are the next version's work, in the gate first. The first is the test machine, not the governor: the model's pod start time was fitted to the empty-node image unpacking of the single kind host (`docs/POD_START_WAIT.md`, section 8), and the kind rig now pre-pulls the image. These are our own models (class S), never a benchmark result.

88.7.3 What runs again on it

Everything runs again, A, B and C, from the moment v11 lands (`scripts/reruns.txt`, the omni-v11 campaign, released by the conductor a few at a time each tick). The grid runs on its own manifest (`results/grid_v11/`), and every Azure set starts again from A. The omni-v10 runs already started run to their end as omni-v10's record; nothing is cancelled, and no table pools the two. Google Cloud and Amazon run the same four sets from A once their queues are switched back on (Google's key stored whole, Amazon's account on its Paid plan). The GPU runs on Lambda wait for the founder's word and one exact commit.

88.8 Omni v12: a refused raise is held, and the swarm's reflex acts at once (the engine that stood 19 to 20 October)

Omni v12 stood on main from 19 to 20 October; on the evening of 20 October Omni v13 (`docs/OMNI_V13.md`) took its place, which is omni-v12 with the conveyance's hand-back. This page stays as omni-v12's record, read beside no other engine's. The founder's order behind it, of the night of 19 October: "Of course I want you to land version 12. I want you to keep fixing and building and straightening and enhancing and benchmarking and defensibility, and every time you do that ... it becomes a new version." It is omni-v11 (`docs/OMNI_V11.md`) with two faults fixed, both found on the omni-v11 runs on 19 October: one in the Kubernetes governor's conveyance, one in the swarm's wire. Every setting, gain, preset and muscle is omni-v11's, and so is every rule but these two.

Its fingerprint is `OMNI_V12.json` (digest `d38b58fbe28939b8`, 47 files). Forty-six files are omni-v11's bytes; one differs, the governor's muscles (`omni_controller/muscles.py`). The swarm's wire (`tools/run_swarm.py`) sits outside the fingerprint's scope, as the data-store wires do (it is versioned by git and tested); its change is declared here as part of omni-v12, and a swarm table counts only on a commit that carries it. Both changes were proven in their tests and in the model gate before they landed (`results/model_gate/V12_VS_V11.md`, `results/model_gate/V12_SWARM_REFLEX.md`). Every benchmark runs again on omni-v12, A, B and C, from the conductor's campaign of 20 October, 00:30 UTC. Every earlier table stands as its own engine's result until its three runs on v12 land, and results from two versions are never pooled. The readings below are our own models (evidence class S), never a benchmark

result. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

#	Change	Where	The fault it fixes
1	A raise the cluster's admission refuses is not written again until the pod's limit changes, the raise shrinks, or a wait passes (5 minutes, doubled at each refusal up to an hour)	`omni_controller/muscles.py`, the conveyance	omni-v11 capacity test: admission refused every CPU-limit raise (`exceeded quota: omni-cap`) and the governor wrote it again at every fast check, about 9 refused writes a minute, 970 to 1,000 an hour (`results/STEERING.md`)
2	The swarm's proximity reflex hands back the planner's cruise in the tick it is triggered; its reach grows with the square of the speed (0.5 m at the planner's cruise, as before)	`tools/run_swarm.py`, `Drone.step`	the omni-v11 reflex let the override fall 0.01 a tick, so a drone kept flying fast about a second after it saw a neighbour; on one mission draw outside the counted cells two drones came within 0.083 m (`results/model_gate/V12_SWARM_REFLEX.md`)

88.8.1 The refused raise

On the kind rig the governor's role cannot read the namespace's quota. As written since omni-v7, an unreadable quota is "no budget known", and the cluster's admission is the authority. In the omni-v11 capacity test admission refused each raise; the refusal was read back and audited, so nothing wrong was ever set, and the table read STEADY. But the governor asked again at every fast check: a controller that repeats a refused command every few seconds loads the API server and fills its own audit. In omni-v12 the refusal is the authority's answer. The same raise is held until something changes: the pod's limit (another writer moved it), a smaller raise (the budget moved), or the wait (5 minutes, then 10, 20, 40, 60, never longer). An accepted raise clears the hold. The audit records each hold and its wait (`held_s`), and `omni_errors_total` and `omni_writes_total` (`tools/omni_exporter.py`) show it to the operator.

The model gate's `convey_refused` model (the quota unreadable and every raise past the operator's limit refused, seeds 1 to 8): omni-v12 wrote **49.75 commands a day against omni-v11's 1,985.5 (−97.5%, GAIN)**, and every other gauge was identical to omni-v11's to the last digit: requests served, pod start wait, p95, alert minutes, host busy, CPU given and pod-seconds. On the convey models with a readable quota and with an unreadable quota that admission accepts, omni-v12 and omni-v11 are identical on every gauge. Tests: `tests/test_refused_raise.py`.

All patents, copyrights and trademarks filed in the USA.

88.8.2 The swarm's reflex

`results/model_gate/V12_SWARM_REFLEX.md` holds the whole reading on gym-pybullet-drones, an outside simulator, on the counted cells and on mission draws the wire was never run on. With the fix, every drone stays at or outside the keep-out on every cell and draw tried, and 49% to 92% of omni-v11's energy cut is kept. That is the price of the reflex acting at once: on the long cell the energy cut falls from −19.8% to −14.5% against native, power given back to the margin between the drones.

88.8.3 The model gate against omni-v11

`results/model_gate/V12_VS_V11.md` (seeds 1 to 8; the cluster models at 60 s and 15 s and with the blink, the three convey models and the verdict model at 20 and 200 pieces of work a decision): omni-v12 reads **identical to omni-v11 on every gauge of every model but one**, the convey model whose every raise is refused, where it writes 97.5% fewer commands (GAIN). No reading of omni-v12 against omni-v11 is a LOSS. The standing engine's own readings against native in these models are omni-v11's and unchanged.

88.8.4 Studied and left out: the verdict's upper end (branch `v12-verdict-study`)

The candidate as first built also carried a stricter verdict: a step kept only when the upper end of every 95% interval of its change in cost is inside the 2% allowance, each phase measuring as many pieces of work as a free step needs to show that, and a trial that could not be read in its time never started. It answers a real fault (omni-v11 keeps a step whose interval reaches past the allowance on its estimate alone: on noisy work a step that truly costs 3% is kept about a quarter of the time). On work fast enough to read a step it kept a free step 98% of the time against omni-v11's 66%, and a 3% step 0% against 26%. But in the model cluster set from a real run's regime the governor reads about 80 requests a decision and the rule needs about 4,000 a phase: 1,102 of its give-back trials never started, no step was allowed, and the governor read identical to native, omni-v11's machine-hour and energy cuts gone (shown under each cluster table of `V12_VS_V11.md`). On the data stores (one cost sample a second, 40 to 120 a phase; 432 to 23,430 needed, read from the omni-v11 audits) every knob would stay native. Refused as written; the fault stays on the next version's list (`docs/CHANGE_CONTROL.md`) until a trial design that reads a 2% step in a trial's time is shown in the model gate.

88.8.5 What stays omni-v11's

Every other engine file, rule, gain, preset and muscle; the verdict (`omnicompass/verdict.py`) byte for byte; the control panel, the gauges feed, the alert rules and the steering report, which sit outside the engine and read or drive it only through the interfaces it already has (`docs/OBSERVABILITY.md`). The next version's list (`docs/CHANGE_CONTROL.md`) carries what is still to fix: the power cap's band, the after-kill window widened to 300 s, the Redis harness's brain in its own process, the commands without a shell, every governor wire in the fingerprint, the Kubernetes governor counting a worker an add-on marks while it serves, and the verdict's reading of a step. The kind rig's governor role still cannot read the namespace's quotas: the Operator's Manual, section 5.5, makes that grant optional, and the omni-v12 capacity rerun reads the hold in the real cluster.

All patents, copyrights and trademarks filed in the USA.

88.9 Omni v13: no other muscle's room is conveyed (the engine that stood 20 to 21 October)

Omni v13 stood on main from 20 to 21 October; on 21 October Omni v14 (`docs/OMNI_V14.md`) took its place, which is omni-v13 with a knob for every muscle and the operator's commands run without a shell. This page stays as omni-v13's record, read beside no other engine's. The founder's order behind it, of 19 October, night: every fault found is fixed, and every fix is the next version, told, not asked. It is omni-v12 (`docs/OMNI_V12.md`) with one fault fixed, found on the omni-v12 runs of KubeRay's rig on 20 October: the governor's conveyance, which hands a machine's idle processor to the serving pods on it, kept handing it on a shared host after the host had none left, and the batch muscle beside the web paid. Every setting, gain, preset and muscle is omni-v12's, and so is every rule but this one.

Its fingerprint is `OMNI_V13.json` (digest `0088837333c6f0fc`, 47 files). Forty-six files are omni-v12's bytes; one differs, the governor's muscles (`omni_controller/muscles.py`). The change was proven in its tests (`tests/test_convey_handback.py`) and in the model gate before it landed (`results/model_gate/V13_VS_V12.md`). Every benchmark runs again on omni-v13, A, B and C. Every earlier table stands as its own engine's result until its three runs on v13 land, and results from two versions are never pooled. The readings from the model gate below are our own models (evidence class S), never a benchmark result. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

#	Change	Where	The fault it fixes
1	On a shared host (kind) at its top (busy at or over 75%), while another workload there has room of its own (a pod, not a serving one, whose limit is above its request), every limit given goes back to the operator's; it is conveyed again only under 70%, the band's 5% cushion below the top	`omni_controller/muscles.py`, the conveyance	KubeRay's rig, the organism alone (`results/live/V12_KUBERAY_4W_BARE.md`): the web pods' limits were raised to 3,700m in the queue's first half minute and kept through the saturated queue; the batch queue finished 0.6% to 0.8% later and the web's 99th percentile rose 4% to 13%, LOSS in all three runs
2	Every other pod on a machine is counted by what it may use: its own limit where it has one, its request where it has none	the same	omni-v12 counted requests alone, so a batch pod's room between its request (500m) and its limit (1 core) read as idle and was conveyed

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

88.9.1 What the KubeRay runs show

The table's two LOSS rows were first put down to the give-back, the governor parking machines during the queue (the batch preregistration, amendment 10). The repetitions' own files say otherwise (`docs/BATCH_QUEUE_PREREGISTRATION.md`, amendment 11). Twenty-nine paired repetitions of the organism alone, A, B and C:

- **The cost sits where the host was saturated.** In 16 repetitions the native queue ran past 760 s: the runner's processor was slower and the batch filled the kind cores (the host's busy share 0.78 through the queue, 95% of readings at or over 0.75). There, each batch pod hashed its work in 63.1 s with Omni-Compass on top against 59.2 s natively, **+7.6%**, and the queue finished 1.1% later. In the other 13, where the host kept room, the same pods read +0.3% and the queue +0.1%.
- **No machine was parked during a saturated queue.** Six workers were in service through the queue in both arms in all 16; the machines Omni-Compass gave back were given back after the queue. The give-back is not the cause.
- **The web's limits were raised at the queue's start and kept.** In 15 of the 16 the conveyance raised the web pods' limits to 3,700m at 33 s (one at 65 s), on a reading of the host's busy share averaged over the 15 s since the governor's previous reading, which caught the dip as the stream's first pods started. From then on the host was at its top, so omni-v7's guard held every further raise, but limits already given stayed, for 92% to 96% of the queue.
- **The web gained nothing while the queue ran.** Pooled over the 29 repetitions, the web's median while the queue ran was 266 ms with Omni-Compass on top against 253 ms natively, its 99th percentile 3,429 ms against 3,226 ms, and the requests served the same (14,454 against 14,480). After the queue, with the host free, the conveyance did what it is for: the median fell from 114 ms to 69 ms and the 99th percentile from 194 ms to 113 ms.

So the lifted quota bought the web no processor on a host with none to spare (the kernel shares a saturated host by the weights of the requests, and the web's share there sat under its operator's limit), and the batch pods lost work per processor second while it was lifted. One saturated repetition had no raise during its queue and still read +4.0% on hashing: one repetition is not a reading, and the omni-v13 runs read what remains of the governor's other costs on the shared cores.

88.9.2 The rule

A limit above the operator's is idle processor conveyed. On a host at its top there is none, and what the serving pods take there beyond their operator's limit can only come out of what another muscle may use. omni-v13 hands it back. The hold is on a shared host only, where the nodes are containers on one machine and the machine's busy share is read directly; on separate machines each node's own arithmetic bounds the conveyance, now with every other pod counted by its limit, so every muscle on the machine can reach its own limit at the same moment as the serving pods reach theirs. A host where no other workload has room of its own (a web-only rig: system pods with no CPU limit, or a limit equal to the request) keeps omni-v7's rule: raises held at the top, limits given stay, because what the serving pods use there is the host's own idle and no

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

other muscle's room. A host whose busy share cannot be read is blind, never at its top (omni-v11): raises held, nothing handed back. The audit names each hand-back (`"convey": "handed back"`) and each write gives the reason and the host's busy share.

88.9.3 The model gate against omni-v12

`results/model_gate/V13_VS_V12.md` (seeds 1 to 8). A new model, `convey_batch`, sets the batch muscle of KubeRay's rig beside the serving one on the batch rig's host: the kind nodes on 3 of 4 cores and the governor on the fourth, the stream of 24 jobs (one every 30 s, ten pods each, five at a time, 500m requested and a 1-core limit), each pod's work set so the native queue finishes where the saturated runners' did (834 s), the processor shared between cgroups by the weights of their requests, the pods' measured start lag (2.66 s) and the governor's own windowed reading of the host. The batch pods' loss of work while a serving pod's quota is lifted on a host at its top is the saturated repetitions' own (+7.6% hashing time, 0.071 of the work).

Against omni-v12, on the same seeds, **no reading is a LOSS in any model**:

- The three cluster models (a decision every 60 s, every 15 s, and with the machines blinking out of the reading) and the verdict model at 20 and 200 pieces of work a decision: identical to omni-v12 on every gauge, to the last digit. The cloud setting conveys nothing, and the verdict is omni-v11's byte for byte.
