- The three web-only convey models (the quota readable and empty, unreadable, and refusing every raise): identical on every gauge. No other workload there has room of its own, so omni-v7's rule holds unchanged.
- `convey_batch`: against omni-v12, the batch queue finishes **1.48% sooner** and the job turnaround is **9.59% shorter** (GAIN), the web's 95th percentile **17.4% lower**, the requests served 0.43% more, the pod start wait 1.46% shorter, the commands written 15% fewer, the CPU given 1.2% less and the host's busy share 0.5% less (GAIN); the pod-seconds +0.84%, power given; the alert minutes identical.

Against native in `convey_batch`, omni-v12 read LOSS on six gauges: the queue +1.50%, the job turnaround +10.7%, the 95th percentile +14.8%, the requests served −2.5%, the pod start wait +1.9% and the alert minutes +9.8%. omni-v13 reads the queue identical to native's, the 95th percentile (−5.3%) and the start wait STEADY, and three LOSS rows. The job turnaround +0.05% (0.04 to 0.17 s a job): the queue's first reading spans the seconds before the batch pods ran, so the web's limits are raised once and handed back 15 s later; the rule that closes it is on the next version's list. The requests served −2.1% and the alert minutes +9.8%: both engines read the same way with no batch at all on this 3-core host, while the real KubeRay runs served 4% more after the queue, so the model's web model is out of its regime there (section 88.3.4). These are our own models, class S.

88.9.4 What stays omni-v12's

Every other engine file, rule, gain, preset and muscle; the verdict (`omnicompass/verdict.py`) byte for byte; the refused-raise hold; the swarm's reflex. The next version's list (`docs/CHANGE_CONTROL.md`) carries what is still to fix, with one item added: the model's web model on the batch rig's 3-core host, where

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

both engines read fewer requests served than native (section 88.3.3) while the real runs read more after the queue, is to be brought to that host's regime from a real run's files.

88.10 Omni v14: a knob for every muscle, the operator's commands without a shell (the engine that stands since 21 October)

Omni v14 was the engine on main on 21 October, from 04:47 UTC until omni-v15 (`docs/OMNI_V15.md`) landed that evening. The founder's orders behind it: knobs on every monitor, "to turn off and on such a mechanism, a muscle, or tweak and turn any muscle" (20 October, evening), and, the next night, "tune the engine". It is omni-v13 (`docs/OMNI_V13.md`) with two changes, each written before it was built and read in the model gate against omni-v13 on the same seeds before it landed: a knob that leaves any one muscle native, and the operator's own commands run without a shell. Every setting, gain, preset and muscle is omni-v13's, and so is every other rule. A third change, to the conveyance's reading on a shared host, was built, tried in the gate and refused there; it is not in omni-v14 (section 88.3.3).

Its fingerprint is `OMNI_V14.json` (digest `7afba44615fcff8f`, 47 files). Forty-five files are omni-v13's bytes; two differ, the Kubernetes governor (`omni_controller/controller.py`) and its muscles (`omni_controller/muscles.py`). Every benchmark runs again on omni-v14, A, B and C. Every earlier table stands as its own engine's result until its three runs on v14 land, and results from two versions are never pooled. The readings from the model gate are our own models (evidence class S), never a benchmark result. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

#	Change	Where	Why
1	`--native MUSCLE[,...]` leaves each named muscle where native runs it: never written, the rest running as before; a name that is not a muscle is refused at the start	the governor and its muscles; the control panel's muscle button	the founder's order of 20 October: a knob for every muscle; and his rule that a muscle Omni-Compass would hurt stays native
2	The operator's own commands (the site power reading, a muscle's read command, a wall meter's `cmd:`) run without a shell unless they hold a pipe, a redirect or a variable	`run_operator_cmd` (`omni_controller/muscles.py`), `tools/wall_meter.py`	the static scan's three high findings (`docs/SECURITY_SCAN.md`); the governor's site power reading no longer reaches a shell at all

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

88.10.1 The knob

`--native MUSCLE[,MUSCLE...]` (or `OMNI_NATIVE`) names the muscles the governor leaves native. A muscle named there is never written: it stays where native runs it, and every other muscle runs as before. The governor still reads the whole body and decides with all of it in view; only the write of a muscle left native is withheld, and the audit says so (`"held"`, and `"native_muscles"` at the start). A name that is not a muscle is refused at the start, never ignored, so a misspelling can never leave a muscle driven that the operator meant to leave native. With no name given, nothing is left native and the governor runs exactly as omni-v13 does.

Muscle	What is left native
`machines`	the node pool's size (the operator's node-scale command)
`replicas`	the pod autoscaler's target, the pod reflex's replica floor and the replica cap
`cpu`	the serving pods' CPU limits (the conveyance and the pod power cap)
`clock`	the processors' frequency ceiling
`gpu`	the GPU's power limit
`rollout`	the rollout guard (pause and undo)
`batch`	the batch admission and pacing
`rightsize`, `coldstart`, `contain`, `cooling`	the pods' rightsizing, the cold-start reserve, the namespaces' containment, the cooling setpoint

The control panel (`tools/omni_control.py`) carries it as one more button, `POST /v1/muscle {"muscle": NAME, "on": true|false}`, role operator, every press audited with its holder and reason, and as a row of On and Native buttons on the console. Like a dial press it passes through native: the governor's own kill file is set, its exit awaited (every setting it wrote restored and read back), and it starts again with the new list. Nothing is changed under a running governor. The monitor wall on the live engine page (`docs/engine/OMNI_COMPASS_LIVE_ENGINE.html`, `#s-wall`) points every row at these buttons; the wall itself never presses one. Tests: `tests/test_native_muscles.py`.

88.10.2 The operator's commands without a shell

A command the operator configured (`--power-cmd`, a muscle's read command in the wiring file, a wall meter's `cmd:`) is split into its words as a shell would split them and run directly when it holds nothing only a shell reads: no pipe, list, redirect, subshell, variable, substitution, glob, home directory, comment or `NAME=value` before the command. One that does runs through the shell as before, so no operator's wiring changes. Tests: `tests/test_operator_cmd.py`. The static scan reads two high findings where it read

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

three (`docs/SECURITY_SCAN.md`): the governor's own call to a shell is gone, and the two that remain are the fallback for a command that needs one.

88.10.3 Refused by the gate: the conveyance's reading on a shared host

The fault it was meant to fix: on the model set from KubeRay's rig (`results/model_gate/V13_VS_V12.md`), omni-v13 raises the web pods' CPU limits once early in the batch queue and hands them back 15 s later, and the batch's job turnaround reads +0.05% against native, a LOSS by the key. The governor reads the host's busy share as the change in its processor counters since its previous reading (every 15 s); the trace of that raise shows it lands on the reading the second job's pods are starting at, before their load is in the reading.

Three rules were written and tried, each against omni-v13 on the same eight seeds:

- **No raise on any reading older than another workload's newest running pod.** Refused: the web's 95th percentile read 6.4% higher than omni-v13's, a LOSS.
- **No raise on the reading that opens another workload's run** (none of its pods with room running at the previous reading). It never fires in the model: identical to omni-v13 on every gauge, because the batch is already running when the second job arrives.
- **That rule, and the starting pods counted:** a pod of another workload still starting ran for none of the interval, so what it may use is added to the reading, and nothing is raised when the sum reaches the 70% cushion. It fires where the fault is. The batch turnaround returns to native's exactly, and the web's queue period is native's second by second. But the web's 95th percentile reads 6.4% higher than omni-v13's, a LOSS. Traced seed by seed: omni-v13's one raise costs the batch pods 15 s of work, which moves when every later batch pod finishes, and with it the seconds the web runs on its last pod; in six of eight seeds that lowered the web's 95th percentile against native. Without the raise the web's queue is native's, and the gain that rode on the batch's delay is gone.

By the gate's rule a LOSS row is not carried into a real run, so none of the three is in omni-v14. They are kept on the branch `v14-convey-study` with their tests and the model's readings. The next version's list (`docs/CHANGE_CONTROL.md`) carries the work that comes first: the model's web model set from a real run's own files (its record already says it is out of its regime on the 3-core batch host), then the third rule read again. The gate found one fault in the model itself and it is fixed for both engines: a batch pod was listed as Running from the moment it was made; a cluster lists it as Pending until its container runs (the rig's own pod start, about 3 s).

88.10.4 The model gate against omni-v13

`results/model_gate/V14_VS_V13.md`: the shipped controller on the model cluster in the cloud setting at 60 and 15 s and with every worker out of service for two minutes, the conveyance on one kind host (readable quota, unreadable quota, a quota that refuses every raise, and the batch muscle of KubeRay's rig beside the serving one), and the verdict on noisy work, eight seeds each, the same seeds for both engines. Every one of the 57 gauges reads identical between omni-v14 and omni-v13, and the verdict allows the same

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

share of give-back steps at every cost: no LOSS. That is what both changes should read there: with no muscle named, the knob leaves nothing native, and no model calls an operator's command. The knob's own behaviour is proven in its tests (a muscle named is never written, an unknown name is refused, every other muscle runs as before), and the commands' in theirs.

88.10.5 What stays omni-v13's

Every other engine file; every rule, gain and guard, the conveyance and its hand-back of omni-v13 among them; the verdict byte for byte. The next version's list (`docs/CHANGE_CONTROL.md`) carries what is still to fix. The GPU governors (`omni_controller/gpu_governor.py`, `gpu_compass.py`) keep their own two levers, the power limit and the clock, and take the per-muscle knob with the version that next changes them.

88.11 Omni v15: the power cap's request through the line's own clear time, every wire in the fingerprint (the engine that stood 21 to 22 October)

Omni v15 was the engine on main from 21 October, evening, until omni-v16 (`docs/OMNI_V16.md`) landed on 22 October, under the founder's standing order that every fault found is fixed and every fix lands as the next version, told, not asked (19 October), and his word of 21 October ("push, push, push on GitHub, update, enhanced engine"). It is omni-v14 (`docs/OMNI_V14.md`) with one change to the brain and one to the fingerprint, each written before it was built and read in the model gate against omni-v14 on the same seeds before it landed: the brain's request for the power cap trims only while the response line has been clean for the governor's own clear time, and every wire that holds a governor's rules is inside the fingerprint. Every gain, guard, preset and muscle is omni-v14's, and so is every other rule. A third item declared with it is not an engine change: the kill test's reading after the kill is 300 s wide (section 88.3.3). A second form of the first change, a dwell with a glide, was built, read in the gate and refused there; it is not in omni-v15 (section 88.3.1).

Its fingerprint is `OMNI_V15.json` (digest `0a53cdd7a558f803`, 55 files). Forty-five of its files are omni-v14's bytes; two differ, the brain (`omnicompass/adapter.py`) and the card governor (`omni_controller/gpu_governor.py`); eight are the wires taken into the fingerprint with this version, their bytes as they stood (`tools/run_redis.py`, `run_kafka.py`, `run_pgbench.py`, `run_sysbench.py`, `run_ycsb.py`, `run_swarm.py`, `run_mujoco.py`, `run_cpu_power.py`). The C++ twin of the brain (`cpp/src/governor.cpp`) carries the same change and is proven equal to the Python again (`tests/test_cpp_governor_parity.py`, on an observation stream that now carries the line's clear flag; `results/SEAL.json`). Every benchmark was to run again on omni-v15, A, B and C; none started before omni-v16 replaced it, because the grid's conductor read omni-v15's commits as no engine (its own copy of the version tool's scope predated the eight wires; fixed on 22 October, `CHANGELOG.md`). Every earlier table stands as its own engine's result until its three runs on v15 land, and results from two versions are never pooled. The readings from the model gate are our own models (evidence class S), never a

All patents, copyrights and trademarks filed in the USA.

benchmark result. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

#	Change	Where	Why
1	The brain trims the power cap to demand only while the response line has been clean for the governor's own clear time; a breach, or a line not yet clean, releases the request to the start limit in the same decision	`omnicompass/adapter.py` (the `power` rule, `observe_vector`'s `clean`), its C++ twin `cpp/src/governor.cpp`; the card governor hands the brain its clear flag (`omni_controller/gpu_governor.py`)	on the omni-v11 long run the request switched between the start limit and the trim at 126 of 350 decisions and turned back at 123 of them, at the one threshold on the queue and the state (`docs/CHANGE_CONTROL.md`, "the next version's list")
2	Every wire that holds a governor's rules is in the fingerprint	`tools/omni_version.py` (`SCOPE`; a version declared before them is read without those eight wires and only those)	a rule in a wire outside the fingerprint could change without the version changing (the swarm's reflex did, in omni-v12)
3	Declared, not an engine change: the kill test reads the 300 s after the kill, where it read 120 s	`tools/live_reps.py`, `docs/ROBUSTNESS_PREREGISTRATION.md` ("On omni-v15"), `tests/test_robust.py`	the one tail rise of the omni-v11 kill test came 140 to 190 s after the kill, past the window declared

88.11.1 The request through the clear time

The fault. The brain (`omnicompass/adapter.Governor`) asks for a power cap at every decision: when the queue is under its guard (q < 0.05) and the state's U is at or over the gate (0.85 in the fleet law), the request is the trim to demand, clamp(cap_now × load × (1 + margin), cap_min, 1); otherwise it is the start limit, 1. On the omni-v11 long run (run 39173420146, the robustness long scenario: three paired repetitions of two hours on real Kubernetes, the wandering load) the governor's own audit shows the request switching between 1.0 and 0.695 (the fleet law's floor, which the trim reached at every calm decision) at 126 of its 350 decisions, and turning back the other way at 123 of them (41 of 116, 36 of 118 and 49 of 116 in the three repetitions; `results/STEERING.md` reads it as moves and reversals an hour). Each switch was the line breached (the controller folds the response-time pressure into the queue reading) and the next decision calm again. On Kubernetes the power wire is off, so nothing was written; but the card governor reads the same request for the GPU's power limit, and a request that hammers at one threshold is not the compass law's way (a band with cushions, smooth, not hammering).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The rule. The Kubernetes governor already declares the reflex: while the response line is breached, and for its clear time after (`--slo-clear-s`, 180 s), Omni-Compass may not pack replicas tighter than the HPA's target and may not cap power. It handed that flag to its muscles and not to the brain, whose request kept trimming the moment one decision read calm. The card governor applied the same gate outside the brain (`cap = requested if slo_clean else 1.0`, its `--slo-clear` 3 decisions). omni-v15 puts it inside: the observation vector carries the line's clear flag (`slo_clean`; a caller that senses no line is clean), and the trim is asked for only while it is set. A breach, or a line not yet clean for the clear time, releases the request to the start limit in the same decision; the spread under backlog at the power envelope and the backlog bound are untouched. No constant is added to the law: the clear time is each governor's own, as it already declared it.

Read on the run's own decisions. The three audits' decisions (their queue reading, state U, clear flag and the request recorded) are kept as a fixture (`tests/fixtures/robust_long_39173420146_decisions.json`, the source files' SHA-256 inside). The recorded request is omni-v14's rule on the recorded queue and state, decision for decision. On the same decisions, read with the recorded clear flag, omni-v15's rule leaves 35 moves of 126, 32 reversals of 123, and 28% of the travel (`tests/test_cap_band.py`). A fault's fix is read first where the fault was found.

Refused by the gate. A second form was written first: a dwell of three calm decisions and a glide of 0.05 a decision toward the trim, the release at once. On the run's own decisions it reads 67 moves and 33 reversals; but in the model gate, where the model cluster's calm stretches are long, the glide turned each trim into seven small moves (the request's moves in a day 149 against omni-v14's 38 on one seed, the travel the same), and on the model card it wrote the limit 25 times against 16 for the same travel and 0.17% more energy. More writes of smaller size is not the fix the fault asked for; by the gate's rule it is not carried. The clear-time gate alone is in omni-v15.

The card. With the flag inside the brain the card governor's own gate becomes a second reading of the same rule: the model card reads omni-v15 identical to omni-v14 on every gauge (section 88.3.4), as it should, and the GPU's run on Lambda starts from `gpu-omni-v15`, one exact commit.

88.11.2 Every wire in the fingerprint

`tools/omni_version.py` hashes every file whose bytes decide what Omni-Compass does. Up to omni-v14 the scope held the brain, the live governors, the realms and three outside-simulator wires (`tools/run_kil.py`, `run_citylearn.py`, `run_pandapower.py`); the data stores' wires (`run_redis.py`, `run_kafka.py`, `run_pgbench.py`, `run_sysbench.py`, `run_ycsb.py`) and `run_swarm.py`, `run_mujoco.py` and `run_cpu_power.py` were versioned by git and tested but did not move the digest, and one of them carried a fault fixed in omni-v12 without the digest moving (`docs/CHANGE_CONTROL.md`, "Gaps this page names"). From omni-v15 every one of them is in the scope: a change to any rule changes the version. A version declared before them is read without those eight wires and only those: a commit carrying omni-v14's 47 files byte for byte reads omni-v14 whatever those eight wires hold, because its fingerprint never covered them, while any other file omni-v14's list does not name (a new rule, a new module) still makes the tree a different engine

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(`tests/test_omni_version.py`); and the tool prints a version's own digest and file count as its fingerprint records them.

88.11.3 The kill test's reading: 300 s after the kill

Declared before omni-v15's runs, as `docs/ROBUSTNESS_PREREGISTRATION.md` ("On omni-v11") proposed: the kill scenario's paired gauges, the time over the line and the failed requests after the kill, are read over the 300 s after the kill mark, where they were read over 120 s (`tools/live_reps.py`, `ROBUST_AFTER_KILL_S`). The one tail rise of the omni-v11 kill test came 140 to 190 s after the kill, past the old window. The omni-v11 kill table stands as read then; omni-v15's kill runs are read over 300 s from their first. The rig is unchanged (the probe runs through the whole 900 s window).

88.11.4 The model gate against omni-v14

`results/model_gate/V15_VS_V14.md`: the shipped controller on the model cluster in the cloud setting at 60 and 15 s and with every worker out of service for two minutes, the conveyance on one kind host (readable quota, unreadable quota, a quota that refuses every raise, and the batch muscle of KubeRay's rig beside the serving one), the verdict on noisy work, and, new with this version, the GPU governor on the modelled card (the card whose voltage falls with its clock and the card near its voltage floor), eight seeds each, the same seeds for both engines. Every service gauge of every model reads identical between omni-v15 and omni-v14: machine-hours, energy, pending-pod minutes, the HPA's shortfall, the 95th percentile and the alert minutes on the cluster models; requests served, start waits, the 95th percentile, host busy, limits given, pod seconds and writes on the conveyance models; the batch queue and turnaround; requests served, the 95th and 99th percentiles, energy, peak temperature and the limit's writes, moves, reversals and travel on both card models (the card governor applied the same gate outside the brain, so the brain's gate inside changes nothing there: 17 writes, 16 moves and 15 reversals a run on the card whose voltage falls with its clock, 35, 34 and 33 on the card near its floor, the same in both engines); and the verdict allows the same share of give-back steps at every cost. The request's own wear is the one place the two engines differ, and it reads STEADY: on the model cluster, where the response line is breached in about 27 of a day's 1,440 minutes and the calm stretches between are long, the request moved 67.3 times a day against 64.9 (+3.7%, STEADY), turned back 66.1 times against 63.8 (+3.7%, STEADY) and travelled 20.4 against 19.6 (+3.9%, STEADY) at a decision every 60 s; at a decision every 15 s 98.8 moves against 100.1 (−1.4%, STEADY), 96.1 reversals against 97.5 (−1.4%, STEADY), 29.3 travel against 29.7 (−1.4%, STEADY); with the blink, +3.0%, +2.9% and +3.0%, STEADY. The small rise at 60 s is the gate doing what the governor declares: omni-v14 kept trimming while the line was breached by less than the queue guard's 5% (a pressure between 0 and 0.05), and omni-v15 releases there too, so in a regime of rare, light breaches it releases a little more often. The fault was found in the opposite regime, the long run's clustered breaches (126 switches in 350 decisions), where the same gate leaves 35 (section 88.3.1); the cluster model's regime is the cloud setting's, set from a real run's own files, not the long run's, and the next long run on omni-v15 reads the request's moves and reversals an hour in `results/STEERING.md`. No LOSS anywhere: the change lands.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

88.11.5 What stays omni-v14's

Every other engine file, byte for byte; every gain, guard and preset; the conveyance and its hand-back; the verdict. The next version's list (`docs/CHANGE_CONTROL.md`) carries what is still to fix, first among them the Redis harness's brain in its own process (its model, `tools/redis_brain_probe.py`, is read before the harness changes, with the version that changes it) and the model's web model set from KubeRay's after-queue files. The GPU governors keep their own two levers; the brain they call now reads the line's clear flag from them.

88.12 Omni v16: every clock of the governor in seconds; the heartbeat at 15 s

Omni v16 (`OMNI_V16.json`, digest `5c5502f12b1c0ce4`, 55 files) stood on main on 22 October, from the morning until omni-v17 landed that evening (`docs/OMNI_V17.md`: the same engine with the heartbeat a dial, the main engine at 60 s, and the cruise wait never under two readings at a slow beat). Two words of the founder's made it. That night ("Go"), on the plan put to him: put every clock of the Kubernetes governor in seconds, read the decision pace at 60, 15, 10 and 5 s in our own models, and run each pace three times on GitHub's own machines (`docs/PACE_PREREGISTRATION.md`). Then, once the models had read: "15 sec all over heart beat fix update code". So the governor's heartbeat, its full decision, comes every 15 s by default, native's own pod autoscaler's pace, where every engine before it decided every 60 s; the fast checks stay every 5 s. It is omni-v15 (`docs/OMNI_V15.md`) with the clocks changed and the heartbeat set, and nothing else: every gain, guard, preset and muscle is omni-v15's, and 50 of its 55 files are omni-v15's bytes (the five changed: `omnicompass/adapter.py`, `omnicompass/edge.py`, `omni_controller/controller.py`, `omni_controller/muscles.py`, `omni_controller/capacity.py`; the brain's C++ twin `cpp/src/governor.cpp` with it, sealed). Read in the model gate against omni-v15 on the same seeds before it was pushed (`results/model_gate/V16_VS_V15.md`), and the pace read alone on a plant that moves every 5 s (`results/model_gate/V16_PACE.md`). The readings from the model gate are our own models (evidence class S), never a benchmark result. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

88.12.1 Why

Every engine through omni-v15 took its full decision every 60 s. The number was written into the first harness on 26 September, with no reason recorded, and never measured against another; the engine was then tuned at 60 s and several of its rules were written in decisions, which locked 60 s in. Native's pod autoscaler checks every 15 s, the metrics it reads refresh every 15 s, the Cluster Autoscaler scans every 10 s, KEDA every 30 s. The founder asked for 15, 10 and 5 s on 14 October; six rules moved to seconds on 16 October (omni-v7) and the rest did not, so turning the period also changed what the remaining rules meant. omni-v16 finishes the job: turning the period changes only how often the governor looks. The cushion each muscle keeps is set by its

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

own climb, wobble and reaction time in seconds, and is the same at any pace; the pace sets only how soon trouble is seen (within 15 s at 15 s, within a minute at 60 s), and so the default moves to native's 15 s.

The founder asked, before the default was set, whether a longer period would make a larger cushion and a stronger engine. It would not: a longer period leaves the governor blind for longer between looks (up to two minutes at 120 s, while native checks every 15 s), and to stay as safe while blind longer it would have to hold more back, which is less work done. The cushion has its own setting (each muscle's z of 3.09, 99.9% of steps inside it, and the dial's tune-down), and the period is not it.

88.12.2 What counted in decisions, and what it counts now

Every value below is the one omni-v15 used when a decision comes every 60 s (the reference step; `REF_PERIOD_S`).

Clock	omni-v15 (per decision)	omni-v16 (per second)	Where
the brain's blending of each reading	0.339 of the state a decision	1 − (1 − 0.339)^k a decision, k = period / 60 s: 0.339 a minute	`omnicompass/adapter.py` (`Governor.step`, `period_s`)
the brain's inner time	0.1 of its macro interval a decision	0.1 k a decision	the same
the brain's dwell and wait before giving a machine back	1 and 5 decisions (the fleet law)	the same seconds: 60 and 300 s	the same
the brain's machines added or removed	up to 8 and 1 a decision	up to 8 and 1 over the last minute's decisions	the same; the C++ twin `cpp/src/governor.cpp` identically
the compass's damping (kd)	critical damping for the decision period	critical damping at the minute, so the law's push and pull per second are the same at any period	`omni_controller/controller.py`
the compass's velocity smoothing	0.3 a decision	0.3 a minute	the same
the edge's window, narrowing, the floor's forgetting, memory, wobble step	20 decisions; 0.05, 0.9995 a decision; one decision's change	20 minutes; 0.05, 0.9995 a minute; a minute's change	`omnicompass/edge.py` (`pace`)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Clock	omni-v15 (per decision)	omni-v16 (per second)	Where
what a breach teaches the edge	0.1 a decision of breach	0.1 a minute of breach	`omni_controller/controller.py`
machines added past the scheduling floor	one step a decision	one step a minute (the release has been one a minute since v7); the floor's machines at once	the same (`ADD_PERIOD_S`)
a command's time to land (proprioception)	the next decision	a minute, every decision reading it until it lands	the same (`LAND_S`)
the host's busy share (kind's shared runner)	since the last decision	over the last minute	`omni_controller/capacity.py` (`span`)
the heat law	0.86 of the heat kept a decision	0.86 a minute	`omni_controller/muscles.py`
held batch jobs admitted; jobs paused or resumed	one a decision	one a minute	the same
a quiet deployment scaled to zero	3 idle decisions	180 idle seconds (`--coldstart-idle-s`)	the same
the coast toward fewer pods	coast step × period / 60 a raise	the coast step a raise (a raise comes at most once a window)	`omni_controller/controller.py`
the conveyance	every third fast check, never at a decision (so never at a decision every 5 s)	every 15 s, whichever check falls due (`--convey-every-s`)	the same
the loop	each wait began when the step ended (a 60 s decision came every 62 to 67 s on kind)	keeps its own schedule; a missed slot is skipped, never run in a burst	the same (`main`)

Six rules already counted seconds since omni-v7 and stay as they were: the line's clear time, cruise, the strict window, the trial spacing, the wait after a refusal, and a trial's length; so does the release of one machine a minute.

88.12.3 The heartbeat: a full decision every 15 s

The default `--interval` is 15 s and `--floor-interval` 5 s (`omni_controller/controller.py`; before, 60 s and 15 s, every rig and install file setting the fast checks to 5 s). Every place that starts the governor carries it: the rigs (`scripts/kind_bench.sh`, `kind_paired.sh`, `kind_robust.sh`, `kind_full.sh`, `kind_pilot.sh`), the install files (`deploy/install/omni-compass.yaml`, `omni-compass-cloud.yaml`, `deploy/controller.yaml`), the cloud runs (which start it through `kind_bench.sh`), the alert rules' staleness bound (`deploy/prometheus/omni-compass-rules.yaml`: three intervals, 45 s) and the manuals. Each run writes its period beside its files (`omni_interval.txt`), and the receipts read each run at its own (`tools/live_reps.py`; the robustness runs before it at 60 s). The page's controller trace and the modelled traces in the manuals keep the 60 s step they were drawn at, and say so. The levers rig (`scripts/kind_levers.sh`) was left at three, two and three decisions of 5 s when omni-v16 landed: under omni-v14 each of them was a minute of the brain's, under omni-v16 they are 15 s, and the two levers that give back (rightsize, coldstart), which wait for the brain's calm (its contraction authority, about a minute after it starts on an idle reading, `tests/test_pace_clocks.py`), failed three of the rig's 19 checks in the first omni-v16 run (22 October, 13:50 UTC). The rig now runs at the default 15 s for the 3, 2 and 3 minutes its checks were written for, with the idle time before cold start in seconds (120 s), and the levers check runs again, A, B and C (`scripts/reruns.txt`).

88.12.4 At 60 s it is omni-v15

On the model cluster at a decision every 60 s, omni-v16 makes exactly omni-v15's decisions: 4,578 audit records, none different (seed 1; the gate's eight seeds read every gauge identical, on every model). The brain's C++ twin equals the Python at 60, 15, 10 and 5 s (`tests/test_cpp_governor_parity.py`, 4,320 directives each, no difference), and every twin was sealed again after its parity test passed (`results/SEAL.json`). Two changes can be seen at 60 s on a real cluster and nowhere else: the conveyance comes every 15 s exactly (omni-v15: about 3.7 passes a minute), and the loop keeps its schedule (omni-v15's decisions drifted by the steps' own time). The model gate's other columns, each engine against native, read as they read for omni-v15 (the same rows, the same numbers at 60 s), because nothing but the clocks moved.

At 15 s, where omni-v15's rules counted in decisions ran four times as fast, every gauge reads STEADY against omni-v15, and the machines parked over the eight days fall from 4,212 to 1,782 (omni-v15 at 60 s: 1,464): the pace no longer changes what a rule means. As shipped (the model `cluster_shipped`: omni-v16 at its default of 15 s against omni-v15 at its 60 s, each started without a period, as an install file starts it), every gauge reads STEADY: machine hours +2.4%, energy per core-hour −0.5%, the pods waiting for a place −28.5%, the 95th percentile −0.3%, the alert minutes −0.9%. No LOSS against the engine it replaces.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The brain's lock (`results/LOCK_AMENDMENTS.json`) takes an amendment for `omnicompass/adapter.py`: the stack simulator steps at 60 s, so the held-out seeds replay unchanged (`verify.py`).

88.12.5 The pace in our models (`results/model_gate/V16_PACE.md`)

omni-v16 alone, eight seeds of a day each on a plant that moves every 5 s, at 60, 15, 10 and 5 s, each faster pace paired by seed against 60 s and against native. In the cloud's setting (the tune-down, machines alone), against 60 s, every service reading is STEADY at every pace (at 15 s: pending pod minutes −12.1%, the 95th percentile −0.0%, alert minutes +0.5%, machine hours −0.4%) and energy per core-hour falls 2.6% at 15 s (GAIN); the power cap's request moves more (power given). In the kind benchmark's setting (the compass law at the max, every autoscaler sensed), against 60 s, the alert minutes fall 14.7% at 15 s and 18.4% at 10 and 5 s (GAIN), the autoscaler's shortfall 6% at 10 and 5 s (GAIN), and every other reading is STEADY. Omni's own processor: 1.6 to 1.7 s an hour at 60 s, 2.7 at 15 s, 3.4 at 10 s, 5.5 at 5 s (under a thousandth of one core at 5 s); its reads: 1,650 an hour at 60 s, 2,190 at 15 s, 3,600 at 5 s. No LOSS against 60 s at any pace.

Against native, the rows read as the engine reads them at every pace, the old 60 s default included, and some read LOSS. The pods waiting for a place: in the kind setting about four times native's at every pace (pending pod minutes an hour: native 8.2; 32.0 at 60 s, 33.5 at 15 s, 28.8 and 28.6 at 10 and 5 s), LOSS at every pace; in the cloud's setting about twice (20.9 at 60 s, 18.4 at 15 s), LOSS at 15 and 5 s and STEADY at 60 and 10 s only by the seeds' spread; on the model gate's 15 s plant, +121.6% at 15 s (LOSS) and +209.8% at 60 s (STEADY by the spread). In the cloud's setting at 15 s two small rows read LOSS as well: the 95th percentile, +0.47% on the 5 s plant and +0.36% on the gate's (at 60 s +0.49% and +0.63%, STEADY by the spread), and the alert minutes, +2.31% on the 5 s plant (at 60 s +1.85%, STEADY). Against 60 s every one of them reads STEADY, the 15 s point estimates the smaller, so they are the engine's and not the pace's: the faster pace narrows the seeds' spread until the rows clear zero. They are on the next version's list to be root-caused (`docs/CHANGE_CONTROL.md`), beside the blink model's alert minutes (+2.35% against native at 60 s, LOSS, the same in every gate since omni-v13).

88.12.6 The real runs

`docs/PACE_PREREGISTRATION.md`: workflow `benchmark-reps`, five arms in every repetition (native; Omni-Compass on top at its default heartbeat of 15 s; the same deciding every 60, 10 and 5 s), the reruns' steady scenario, three runs of 10 repetitions on GitHub's own machines at no cost, released by the conductor as the campaign's entry `kubernetes decision pace`. They are the real-run reading of the heartbeat the founder set: a LOSS at 15 s there is root-caused and fixed in the next version, as any other.

88.13 Omni v17: the heartbeat a dial; the main engine at 60 s

Omni v17 (`OMNI_V17.json`, digest `7c937d09e4031cc7`, 55 files) stood on main on 23 October, from the afternoon until omni-v18 landed that night (`docs/OMNI_V18.md`). The founder's order of the afternoon before (22 October), once he had read the reads of the cluster a day in the pace study (about 86,000 at 5 s

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

against 39,700 at 60 s): the governor's heartbeat, its full decision, is a dial, "5, 15, 30, 60, 75, 90, 120 ... Heartbeat scaled in its monitors. And you're going to set OmniCompass is main engine", because "who knows if maybe the purpose is somebody wants to set it at 5 seconds"; and before it, "we are going to write the engine to have the 60 ... we have to actually have to be able to show the same 15 second beats". So the main engine takes its full decision every 60 s; any beat can be set (`--interval`, 5 to 120 s and every value between), the fast checks every 5 s at every beat; and every beat is shown beside native with what it buys and what it costs, because an operator may want a fast beat for its reads and accept what it costs, or a slow one, and at each beat the other knobs may want their own combination. It is omni-v16 (`docs/OMNI_V16.md`) with two changes, both in `omni_controller/controller.py` (54 of its 55 files are omni-v16's bytes): the parser's default period moved from 15 to 60 s; and the cruise rule's wait never fewer than two readings, a fault the dial's own ladder found at 90 and 120 s before the version landed (below, "The fault the ladder found"). Every clock of the governor counts seconds since omni-v16, so the dial changes only how often it looks. Read in the model gate against omni-v16 on the same seeds (`results/model_gate/V17_VS_V16.md`), and every beat read beside native and beside 60 s on a plant that moves every 5 s (`results/model_gate/V17_LADDER.md`), before it was pushed. The readings from the model gate are our own models (evidence class S), never a benchmark result. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

88.13.1 Why a dial, and why 60 s for the main engine

Through omni-v15 the governor decided every 60 s, a number written into the first harness on 26 September and tuned around; omni-v16 put every clock in seconds so that the period became a clean setting, and set it at 15 s, native's own pod autoscaler's pace, on the founder's word that morning. The models then showed what each pace buys and costs: a faster beat reads the cluster more often (about 39,700 reads a day at 60 s, 52,500 at 15 s, 86,400 at 5 s), spends more of the governor's own processor (1.6 to 1.7 s an hour at 60 s, 2.7 at 15 s, 5.5 at 5 s, under a thousandth of one core at any beat), and in the kind benchmark's setting sees trouble sooner (the minutes over the line 14.7% fewer at 15 s than at 60 s); against native the same rows read at every pace. No one beat is right for every operator. The founder's order makes the beat the operator's setting, as the tune-down is, and sets the main engine, the one the company ships and benchmarks first, at 60 s, the period every engine through omni-v15 decided at; 15 s, native's own pace, is one setting of the dial, run and shown beside it.

88.13.2 The dial in our own models (`results/model_gate/V17_LADDER.md`)

The engine alone on a plant that moves every 5 s, the fast checks every 5 s at every beat, eight seeds of a day each, the same seeds and plant at every beat: 5, 10, 15 and 60 s from the pace study of omni-v16 (`results/model_gate/V16_PACE.json`, read before omni-v16 landed, each run setting its period on the command line, so it reads the same on omni-v17), and 30, 75, 90 and 120 s run the same way for omni-v17; the native and 60 s runs the two share read the same seed by seed on every modelled gauge to the twelfth digit (the two were run under Python 3.11 and 3.12, whose float sums differ in the last bits of one gauge, the power cap's travel; `tools/beat_ladder.py` refuses a ladder where any shared reading differs

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

by more). The governor's own processor is timed, not modelled, so each beat's is paired only with the 60 s of its own run. Each beat is paired by seed against native and against the main engine's 60 s.

In the cloud's setting (the compass law at the tune-down, the machines alone), each beat's mean over the eight seeds and its word against native:

Beat	Reads a day	Omni's own processor (s an hour)	Pods waiting (min an hour)	95th percentile (ms)	Minutes over the line (a day)	Autoscaler short (min an hour)	Machine-hours (a day)	Energy per core-hour (kWh)

Each beat against the main engine's 60 s, and every gauge in full, is on the ladder's page.

88.13.3 The fault the ladder found: cruise on one reading at 90 and 120 s

The ladder's first reading of 90 and 120 s (kept on its page, "The first reading of every 90 and 120 s, before the fix") put the kind benchmark's setting in another regime from 75 s down: against 60 s the machine-hours +17.1% and +21.4%, the minutes over the line −71.6% at both, the pods waiting for a place −59.4% and −70.7%, the 95th percentile −15.4% and −21.3%, and the machines parked over the eight days 82 and 46

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

against 329. A jump that sharp between two neighbouring beats is a rule's count crossing a threshold, not a pace. The cause is the cruise rule (rule 7: work waiting for a place decision after decision puts every machine in service until the line has been empty as long). Its wait is written in seconds, `--cruise-after-s 120`, and v7 converts every such wait to decisions as n = max(1, round(seconds / period)): 2 at 60 and 75 s, but round(1.33) = 1 at 90 s and round(1.0) = 1 at 120 s. With one decision, a single reading with one pod waiting set every machine in service and a single empty reading let them go: the rule no longer asked for work that waits "decision after decision", the words it is written by. The fix (`omni_controller/controller.py`): the cruise wait is never fewer than two readings, `max(2, round(120 / period))`, when it is derived from seconds; a count an operator sets by hand (`--cruise-after`) stands as set. At every beat up to 80 s the count is what it was (24 at 5 s, 8 at 15 s, 4 at 30 s, 2 at 60 and 75 s), so nothing below 80 s moves; at 90 and 120 s it is 2 (`tests/test_pace_clocks.py`, which fails on the unfixed rule). Corrected, the kind benchmark's setting reads at 90 s, against 60 s, the machine-hours down 1.7%, STEADY, the minutes over the line down 4.7%, STEADY, the pods waiting down 12.1%, STEADY, the 95th percentile down 0.2%, STEADY; at 120 s the machine-hours down 2.1%, STEADY, the minutes over the line down 3.7%, STEADY, the pods waiting down 29.6%, GAIN; machines parked over the eight days 190 and 119 against 329 at 60 s. No other count of the governor's falls to a single reading between 5 and 120 s: the breach's clear time (180 s) is 2 decisions at 120 s, the strict window (300 s) 2, the trial's phase (1,200 s) 10; the brain's dwell is one step by design and its waits round to the nearest step. In the cloud's setting (the machines alone, at the tune-down) every service, machine-hour and energy reading at 90 and 120 s is the same before and after the fix, seed by seed; what moves is the governor's own reads of the cluster, 1.9% and 1.2% more (cruise pauses the five-second floor reads, and it now pauses less often), and the machines parked on three seed-beats (128 against 126, 148 against 147, 83 against 80).

88.13.4 What the slower main engine costs against 15 s

Set at 60 s, the main engine gives up what 15 s bought in the models, and it is disclosed here as the price of the founder's setting: in the kind benchmark's setting the minutes over the line are 23.75 a day at 60 s against 20.25 at 15 s (+17.3%: read the other way, 15 s against 60 s, −14.7%, GAIN, so 60 s against 15 s is a LOSS by the key), still 12.0% fewer than native's 27.0 (GAIN against native); in the cloud's setting the energy per core-hour is 2.6% more at 60 s than at 15 s (power given). Every other row reads STEADY between the two. The model gate's own models read the change as shipped (`cluster_shipped`, each checkout started without a period, as an install file starts it: omni-v17 at its 60 s against omni-v16 at its 15 s): every gauge reads STEADY: the machine-hours −2.3%, the energy per core-hour +0.5%, pods waiting for a place +39.8%, the autoscaler's shortfall +0.2%, the 95th percentile +0.3%, the minutes over the line +0.9%; no LOSS against omni-v16.

88.13.5 The rows against native that read LOSS (the engine's, at every beat)

Read by the one key, these rows read LOSS against native in our models (every seed's paired interval clear of zero):

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- the cloud's setting, every 5 s: pods waiting for a place +101.8%.
- the cloud's setting, every 15 s: pods waiting for a place +124.4%; the 95th percentile +0.5%; the minutes over the line +2.3%.
- the cloud's setting, every 30 s: pods waiting for a place +127.1%; the 95th percentile +0.4%.
- the kind benchmark's setting, every 5 s: pods waiting for a place +248.9%.
- the kind benchmark's setting, every 10 s: pods waiting for a place +251.9%.
- the kind benchmark's setting, every 15 s: pods waiting for a place +309.5%.
- the kind benchmark's setting, every 30 s: pods waiting for a place +316.5%.
- the kind benchmark's setting, every 60 s: pods waiting for a place +290.6%.
- the kind benchmark's setting, every 75 s: pods waiting for a place +256.2%.
- the kind benchmark's setting, every 90 s: pods waiting for a place +243.4%.
- the kind benchmark's setting, every 120 s: pods waiting for a place +175.1%.

They are the engine's at every beat, the main engine's included, and stay on the next version's list (`docs/CHANGE_CONTROL.md`) to be root-caused, beside the blink model's alert minutes (LOSS against native at 60 s in every gate since omni-v13).

88.13.6 The monitors scale with the beat

- The exporter (`tools/omni_exporter.py`) serves `omni_heartbeat_seconds`: the beat the governor runs at, measured as the median time between its last eleven full decisions, so a skipped slot moves it little (`tests/test_omni_exporter.py`, every beat from 5 to 120 s).
- The governor's Grafana screen (`deploy/grafana/omni-compass.json`, eighteen panels) shows the beat and counts the time since the last decision in beats of that setting (yellow past one and a half, red past three).
- The staleness alert (`OmniGovernorStale`, `deploy/prometheus/omni-compass-rules.yaml`) fires after three beats as measured: 180 s at the main engine's 60 s, 45 s at 15 s, 360 s at 120 s; the other rules count in minutes and hours, not decisions.
- The live engine page carries the dial (the page's section 2d, "The heartbeat dial"): every beat beside native, from the ladder, with the real runs' place; its manual reads it (`docs/OMNI_COMPASS_LIVE_ENGINE_MANUAL.md`, section 7.4).
- The control panel (`tools/omni_control.py`) carries the dial as a button: `POST /v1/beat {"seconds": 5 to 120}`, role operator, one console button for each stop (5, 15, 30, 60, 75, 90, 120 s); like a dial press it hands every setting back and starts the governor again at the new beat, and it serves the beat as `omni_control_beat_seconds` (`tests/test_omni_control.py`).
- Every run writes its beat beside its files (`omni_interval.txt`); the receipts read each arm at its own and record it (`tools/live_reps.py`, `"beats"`), and a three-run table names the beat its compass arm ran at (`tools/confirm_abc.py`).

88.13.7 Every place that starts the governor

The parser's default (`--interval 60`, `--floor-interval 5`); the rigs (`scripts/kind_bench.sh` `OMNI_INTERVAL`, `kind_paired.sh`, `kind_robust.sh`, `kind_levers.sh`, `kind_full.sh`, `kind_pilot.sh`); the install files (`deploy/install/omni-compass.yaml`, `omni-compass-cloud.yaml`, `deploy/controller.yaml`); the cloud runs, which start it through `kind_bench.sh`; and all three manuals. The levers rig gives each phase the 3, 2 and 3 minutes its checks were written for, three, two and three decisions at 60 s (`tests/test_pace_clocks.py`).

88.13.8 At 60 s it is omni-v16 at 60 s

omni-v17 changes no gain, preset or muscle, and one rule only at beats slower than 80 s: at any beat up to 80 s set on the command line it makes omni-v16's decisions at that beat (the cruise wait's count is unchanged there), and at 60 s those are omni-v15's (4,578 audit records on the model cluster, none different, `results/model_gate/V16_VS_V15.md`). The model gate against omni-v16 (every model that sets its own period reads identical to omni-v16 on every gauge and every seed (9 models and the verdict); as shipped, omni-v17 at its 60 s against omni-v16 at its 15 s, every gauge reads STEADY; no LOSS against omni-v16.). The brain's C++ twin takes the period on every call and is unchanged (`results/SEAL.json`); the brain's lock takes no amendment.

88.13.9 The real runs

`docs/PACE_PREREGISTRATION.md`, amendment 3 (written before any omni-v17 run): workflow `benchmark-reps`, eight arms in every repetition on the same runner in an order rotated by repetition (native; Omni-Compass on top at the main engine's 60 s; the same deciding every 5, 15, 30, 75, 90 and 120 s), the reruns' steady scenario, three runs of 10 repetitions on GitHub's own machines at no cost, released by the conductor as the campaign's entry `kubernetes decision pace`. Each beat is read against native and against 60 s by the one key; a row that reads LOSS at any beat against native is named on the dial's page and root-caused like any other. Every benchmark runs again on omni-v17 at 60 s (`scripts/reruns.txt`), and the Kubernetes preregistration takes its amendment of the same day (`docs/K8S_COMPASS_PREREGISTRATION.md`).

88.13.10 Next: each beat's own combination

The founder's words: the engine "can always be tweaked, tuned, and turned with any knob, any button", and "when you do this inside, you might need to click and change and turn certain things to achieve a more optimal state with a different combination of buttons". The per-beat tuning is the next study, in the model first, on development seeds: at each beat, the combination of the other settings that reads GAIN with no LOSS against the main engine's tune at that beat; a combination that does lands as the next version, as that beat's card, never forced.

88.14 Omni v18: Omni direct in the engine; the three arms

Omni v18 (`OMNI_V18.json`, digest `1cb92edb64c4391d`, 62 files) stood on main from 23 October, night, to 25 October, when omni-v19 (`docs/OMNI_V19.md`) landed. The founder's orders of the same evening: "Native is Kubernetes on the muscles. Omni on native is Omni on top of Kubernetes on top of the muscles. And then Omni direct is simply Omni on top of the muscles, no Kubernetes ... they all need to be written in code and toned in ... and push it all"; and, once it was pushed, "It should be not 17 anymore, it should be 18 ... Give me this new live engine wired up now to where you're at".

omni-v18 is omni-v17 (`docs/OMNI_V17.md`) with Omni direct taken into the engine: the seven files of Omni-Compass's own orchestrator that hold its rules are fingerprinted like every other wire, so no rule of Omni direct can change without the version changing (the principle omni-v15 set for the eight wires it took in). 55 of its 62 files are omni-v17's bytes; the seven new ones are `omni_orchestrator/__init__.py`, `agent.py` (the machine's hand), `brain.py` (the brain), `cgroup.py` (the walls), `control.py` (the control plane), `front.py` (the front) and `scheduler.py` (the room rule). The showing's workload and clients (`omni_orchestrator/workload.py`, `load.py`) are the harness and stay outside. A version declared before omni-v18 is read without the seven (`tools/omni_version.py`, `ORCHESTRATOR_WIRES`), so every earlier commit keeps the version it ran on.

88.14.1 The three arms

Every organism the orchestrator runs is shown three ways, all three in one showing and every pair read by the one key, paired by step (`tools/orchestrator_show.py`, `.github/workflows/orchestrator.yml`, `docs/OMNI_ORCHESTRATOR.md`):

arm	what moves the muscles	brain
native	Kubernetes' published autoscaling rule, written by us, every machine on, units spread	`yardstick`
Omni on native	that rule's units, never fewer; Omni's reflex and fail-up above it; Omni's conveyance, busy room rule, packing and machines on top; no fold, no verdict (the engine's strict form, as on the kind rigs)	`omni_native`
Omni direct	Omni alone on the muscles, no Kubernetes: everything Omni on native does, and the fold below the rule's count under the verdict	`omni`

88.14.2 What Omni direct carries

Every mechanism in Omni direct's brain is the engine's own, so the same gain goes to Omni on top of native:

- **conveyance** (omni-v7, omni-v13): each unit's processor wall set to the room its machine can spare under 75% busy, shared among the service's units there, never under the request, handed back between 70% and 75% and at the top beside another workload's room; journaled, written to the hand, read back from the kernel's `cpu.max`;

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **the reflex**: work waiting in line adds as many units as there are requests waiting, up to the step, in the same beat;
- **the twin**: Kubernetes' rule read on the same readings, each unit's use counted no higher than its request, as Kubernetes would see it; Omni never holds fewer units than the twin unless the verdict allowed the step;
- **the fold under the verdict** (`omnicompass/verdict.py`): a unit fewer than the twin tried on the service's own response times, under the same traffic (a trial whose arrivals move more than 15% is abandoned), kept only where it reads no LOSS within 2%; work waiting hands a step back at once (the immune reaction);
- **the hold on trials the traffic keeps abandoning** (new with omni-v18): a trial the traffic abandons holds the next off for 6 beats, doubled at each abandonment in a row up to the verdict's recheck (24 beats), cleared by a trial judged to its end; a phase counts its step from the higher of the twin it found and the twin now. Found on the first three-arm showing, where every trial was abandoned yet each held a unit below the twin while it ran (Omni direct against Omni on native, work LOSS, down 5.2%); fixed before the version landed (`docs/OMNI_ORCHESTRATOR.md`, section 2d);
- **the busy room rule** (omni-v7, `omni_controller/capacity.py`): no unit placed onto a machine at 75% of its measured busy share; the units packed onto the fewest machines, machines parked and woken;
- **the journal and the kill switch**: every change journaled before it is acted on and replayed when the control plane starts again; the kill switch holds the declared state and hands every conveyed wall back.

88.14.3 What it read before it landed

Our own showing on one host, class L, one run of each arm (`docs/OMNI_ORCHESTRATOR.md`, sections 2c and 2d):

- **The three arms, quick form** (six steps of 15 s, after the fix): Omni on native against native, work GAIN, up 8.3%; Omni direct against native, work GAIN, up 9.1%; Omni direct against Omni on native, the 95th percentile GAIN, down 13.2%, and units GAIN, a cut, down 9.5%. No LOSS in any pair; nothing failed or wrong in any arm, the batch job or the drills.
- **Omni direct against native, full form** (18 steps of 25 s): work GAIN, up 4.7%; the 95th percentile GAIN, down 9.9%; units GAIN, a cut, down 10.3%; machines STEADY, down 1.7%; 0 failed and 0 wrong in 20,452 requests.

The model gate against omni-v17 (`results/model_gate/V18_VS_V17.md`): every model reads omni-v17's numbers, because none of omni-v17's 55 files moved; the gate's models do not run the orchestrator, whose own gate is the showing above.

And after it landed, the three runs on GitHub's machines (the full form, A, B and C from one commit) read Omni on native against native work GAIN in all three (up 5.2% to 7.4%) and the 95th percentile GAIN in all three (down 7.5% to 12.1%), Omni direct against native work GAIN in all three (up 5.7% to 9.4%) and the 95th percentile GAIN in all three (down 9.8% to 15.7%), machines STEADY, the units power given or

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

STEADY, and Omni direct against Omni on native STEADY on every gauge; no LOSS in any pair in any run (`results/orchestrator/V18_THREE_ARMS_ABC.md`).

88.14.4 What runs on it

Every benchmark runs again on omni-v18: the conductor's campaign counts from 02:51 UTC on 24 October, when the engine reached main, and only runs whose own commit carries `OMNI_V18.json` (`scripts/dispatch_grid.py`, `scripts/reruns.txt`), and the clouds' sets run on it once each cloud's own $0 check passes. In the clouds nothing changes: Omni on top of the cloud's Kubernetes at the tune-down, on the machines alone (the order of 14 October). Omni direct runs on GitHub's own machines, three runs from one commit (`orchestrator.yml`). Omni direct is ready on a rented machine in each cloud and runs there only on the founder's word: the test `direct` on the one-machine buttons (`big-organism-detached.yml` on Azure, `cloud-organism.yml` on Google and Amazon; `scripts/organism_detached.sh`) rents one 8-processor machine, ships it the exact commit, runs the same full form `reps` times one after another, brings every run's files back and gives the machine back; a dry run (the default) shows the price and rents nothing. The GPU runs on Lambda start from `gpu-omni-v18`, one exact commit.

88.14.5 What it does not claim

The three-run reading is the full form on GitHub's machines from one commit, on one host each; no cloud machine has run it yet. The comparison of Omni direct against Kubernetes itself on the kind rig is the next step. The trade between muscles judged on the organism stays the next version's work, through the model gate. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

88.15 Omni v19: Omni-Compass by itself, a pod muscle of its own

Omni v19 (`OMNI_V19.json`, digest `36ee67284c035235`, 62 files) lands on 24 October, 16:54 UTC, under the founder's order of 23 October that every organism is shown three ways: native; Omni-Compass and native; and Omni-Compass by itself, "running direct muscles" with native's own controller of that muscle switched off ("there's native, there's Omni and native, and then there's Omni asked. It is omni-v18 (`docs/OMNI_V18.md`: Omni direct in the fingerprint) with one muscle added to the Kubernetes governor, in `omni_controller/controller.py`, and the models' arm that runs it, in `realms/harness.py` and `realms/plants.py`; 59 of its 62 files are omni-v18's bytes. Nothing moves unless the operator names a workload to the muscle: with no workload named the engine is omni-v18, decision for decision (the model gate below). Preregistered before any run (`docs/SOLO_PREREGISTRATION.md`). Read in the model gate against omni-v18 on the same seeds (`results/model_gate/V19_VS_V18.md`), by itself against omni-v18 by itself arm by arm (`results/model_gate/SOLO_V19_VS_V18.md`) and by itself beside native and beside Omni-Compass and native (`results/model_gate/SOLO_V19.md`) before it was committed. The readings are our own models (evidence class S), never a benchmark result. Run and scored by

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

88.15.1 Why it is omni-v19: one name, two engines

This change was first built on the live engine's branch and landed there on 24 October, 01:30 UTC, under the name omni-v18 (digest `22486290b19349eb`, 55 files, on top of omni-v17), while main's omni-v18 (Omni direct in the fingerprint, digest `1cb92edb64c4391d`, 62 files) had stood on main since 23 October, night. One version number names one engine, and no result is read across engines, so the two are kept apart: the branch's omni-v18 never stood on main, and nothing it recorded is read as main's omni-v18. Its change, the three files above and nothing else in the engine, is taken onto main's omni-v18 here, gated again against main's omni-v18 on the same seeds, and lands as omni-v19. Every rule is the branch's; the code's own comments, which named the branch's numbers (omni-v17, omni-v18), now name omni-v19, so the three files differ from the branch's bytes in those comments only. Main's omni-v18 files and records stay as they were.

88.15.2 The pod muscle of its own

On every engine before it, the Kubernetes governor moved a workload's pods only through the pod autoscaler's own object (its range and its target): with the pod autoscaler switched off it had no pod muscle, so "by itself" held every workload at the operator's count. omni-v19 gives it one (`--own-replicas namespace/name,...`, or `OMNI_OWN_REPLICAS`; `_own_pods`). For each workload the operator names and no autoscaler governs, the governor sets the replica count itself, through the workload's own scale, by strict C's rule: replicas = ⌈current × measured busy share / target⌉, up at once, down only to the highest recommendation of the last 300 s, inside a tolerance of a tenth. The target is the one the compass moves for an autoscaler: the operator's own (the workload's `omnicompass.io/target-utilization` annotation, else `--own-target`), down to 60% of it, the most pods the cover allows past the wall. Never below the operator's own count at the max, never above the range's top (`omnicompass.io/replica-range`), never below one pod; the count it shipped is recorded once on the workload and handed back by the reset. A workload an autoscaler governs keeps its autoscaler: the muscle writes nothing there. `--native replicas` leaves it native and writes nothing; a security hold allows no expansion. The muscle keeps the pace of the controller it stands in for: a reconciliation every 15 s on the fast checks (`--own-every-s`, the pod autoscaler's sync), at the target the last decision set; the compass moves the target only in a decision, at any beat of the dial.

In the models (`realms/harness.py`, `SOLO`; `realms/plants.py`, `native_off`), the arm by itself is the max with every pool whose own count is the muscle's knob run with its autoscaler switched off, and its twin (the brain's sense of native) too. A power cap, an admission limit and every other plant's knob are a setting native already holds still, or run through native's own loop as its actuator: there by itself is the same arm as Omni-Compass and native.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

88.15.3 The fault found before it landed

On the branch, rebuilt on omni-v17, whose main engine decides every 60 s (as main's omni-v18 does), the first candidate moved its pods only at a decision, once a minute. By itself in the model it then read the minutes over the response line LOSS against native (34.8 minutes a day against native's 26.4), the 95th percentile still a GAIN. The pod autoscaler it stands in for syncs every 15 s. The muscle now reconciles every 15 s between decisions; its window of fewer pods counts those reconciliations (the strict window's 300 s at any beat). Two unit tests hold it (`tests/test_own_replicas.py`, 11 in all).

88.15.4 The model gate against omni-v18 (`results/model_gate/V19_VS_V18.md`)

Every model, 8 seeds of a day: the cluster in the cloud's setting at 60 and 15 s, the blink, the shipped default, the four conveyance models, the card and the card near its voltage floor, and the verdict. Every gauge of every model reads **identical** to omni-v18, seed for seed (95 rows, and the verdict's every share; only the governor's own measured processor time, a clock reading, differs from run to run), because no model names a workload to the muscle. Every table is the one the branch's own gate against omni-v17 printed when it landed there, number for number and word for word, as it must be: main's omni-v18 added only Omni direct to omni-v17, and no model runs Omni direct. No LOSS against the engine that stands.

In the models, the native arm and the max read byte-identical on both engines (the preregistration's step 3): 806 readings on the development seeds 7101 and 7102, 67 muscles each under its own load, the climb and the line, and one body of 60 muscles, every reading's hash the same on omni-v18 and omni-v19. The switch acts only in the arm by itself.

88.15.5 The rows against native that read LOSS (the engine's, as on omni-v18)

The same models read against native carry the rows omni-v18 and omni-v17 carry, unchanged, each on the next version's list with its cause: at a decision every 15 s in the cloud's setting the pods waiting for a place LOSS (up 121.6%) and the 95th percentile LOSS (up 0.36%); the alert minutes with the machines blinking out of the reading LOSS (up 2.35%); in the conveyance model the pod start wait LOSS (up 8.99%) and its 95th percentile LOSS (up 10.0%), beside the requests served GAIN (up 64.2%) and the 95th percentile GAIN (down 53.1%); in the batch model the requests served LOSS (down 2.11%), the alert minutes LOSS (up 9.82%) and the job turnaround LOSS (up 0.05%); the card's 95th percentile LOSS (up 2.38%; near its voltage floor up 5.78%), beside its energy GAIN (down 4.72%; down 1.30%). Every row is shown.

88.15.6 By itself, in our own model (`results/model_gate/SOLO_V19.md`, 8 seeds of a day, class S)

On the machines as the kind rig has them (every worker made at the start, no Cluster Autoscaler: 12 machines in every arm):

Gauge	native	Omni-Compass and native	Omni-Compass by itself
machine-hours	288.0	288.0	288.0

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Gauge	native	Omni-Compass and native	Omni-Compass by itself
pods waiting for a place (pod-minutes an hour)	0.0	0.0	0.0
95th percentile response (ms)	80.0	76.8	64.4
minutes over the response line (a day)	26.4	22.0	9.2

By the one key, Omni-Compass by itself against native: the 95th percentile **GAIN** (down 19.4%: faster; its 95% interval down 12.2% to 26.6%), the minutes over the line **GAIN** (down 64.9%: fewer; down 32.4% to 97.5%), machine-hours, energy per core-hour and pods waiting STEADY (the same machines). Against Omni-Compass and native: the 95th percentile **GAIN** (down 16.0%), the minutes over the line **GAIN** (down 58.0%), the rest STEADY. Omni-Compass and native against native: the 95th percentile **GAIN** (down 4.0%), the minutes over the line **GAIN** (down 16.6%). Its own cost: the governor reads each workload it scales twice at each reconciliation (6,417 reads an hour in the model, twelve workloads, against 660 on top of native), the reads power given.

Against omni-v18 by itself, arm by arm (`results/model_gate/SOLO_V19_VS_V18.md`): native and Omni-Compass and native read identical on both engines, gauge for gauge; by itself, omni-v18 has no pod muscle and holds every workload at the operator's count (its 95th percentile 313,407 ms and 1,412 minutes over the line in the day: the model's queue running away), where omni-v19 reads 64.4 ms and 9.2 minutes: the 95th percentile **GAIN** (down 100.0%), the minutes over the line **GAIN** (down 99.3%), the energy per used core-hour **GAIN** (down 4.2%), machine-hours and pods waiting identical. No LOSS in any arm.

88.15.7 Where it runs

On Kubernetes, the kind rig's `ARM=solo` (`scripts/kind_bench.sh`): the pod autoscaler removed after the deploy, the operator's target and range written on the workload, the workload at its range's floor, Omni-Compass the only controller of its pods; Kubernetes' own scheduler and kubelet stay; the kill switch's check reads the workload back at the count it started at and no record of Omni-Compass's left on it. The capture counts the workload's own replicas where no autoscaler stands (`fleet/capture/kube_capture.sh`). The three-run tables read it against native (`solo`) and against Omni-Compass and native (`solo|compass`) (`tools/confirm_abc.py`, `tools/live_reps.py`). Its runs: `kubernetes by itself` in `scripts/reruns.txt`, the steady load with the three arms in rotation (native, Omni-Compass and native, Omni-Compass by itself), A, B and C on GitHub's own machines, written before the omni-v19 campaign opened. In our models, the organisms runner's third arm (`tools/run_realms_v5.py`): every pool whose own autoscaler can be switched off, read against native and against Omni-Compass and native. Where native is a setting, or its own loop is the actuator, the two Omni-Compass arms are one. No cloud runs by itself without the founder's word (the order of 14 October: nothing in a cloud adds a machine).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

88.15.8 Beside it: Omni direct

Main's omni-v18 took Omni direct into the engine: Omni-Compass's own orchestrator (`omni_orchestrator/`, `docs/OMNI_ORCHESTRATOR.md`) runs the organism with no Kubernetes at all, with its own walls, hand, front, room rule, brain and control plane, its seven rule files fingerprinted with every other wire. omni-v19 carries those seven files byte for byte. The two answer the same order from two sides: Omni direct replaces Kubernetes on the muscles (its arms native, Omni on native and Omni direct, `tools/orchestrator_show.py`); Omni-Compass by itself stays on Kubernetes, which still places and runs the pods, and switches off only the controller of the knob (on the kind rig the pod autoscaler), the governor its only controller.

88.15.9 The real runs

Every benchmark runs again on omni-v19 (`scripts/reruns.txt`; the conductor's campaign from 16:54:55 UTC on 24 October, the moment it stands), and `ARM=solo` joins the kind sets beside native and Omni-Compass and native, three runs, read by the one key.

88.15.10 What it does not claim

No real run of the arm by itself has been made yet: every reading on this page is our own model (class S). The trade between muscles judged on the organism stays the next version's work, through the model gate. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

88.16 Omni v20: the data stores' wires fixed at their causes

Omni v20 stood on main on 25 October until omni-v21 landed that evening (`docs/OMNI_V21.md`).

Omni v20 (`OMNI_V20.json`, digest `1df07f8e36a97985`, 62 files) lands on 25 October, 13:24 UTC, under the founder's words of 25 October ("Fix, fix, fix ... The SYS bench, Kafka, whatever ... has got a problem, you got to fucking fix it ... it can be fixed") and the standing order that every fault found is fixed and lands as the next version, told, not asked. It is omni-v19 (`docs/OMNI_V19.md`) with five of its wires changed: the data stores' runners `tools/run_sysbench.py`, `tools/run_kafka.py`, `tools/run_ycsb.py`, `tools/run_redis.py` and `tools/run_pgbench.py`. 57 of its 62 files are omni-v19's bytes. The faults were found by tracing why the Omni index read +4.32% before the 0.5% key of 24 October and +3.397% after it (`docs/STORE_LOSS_ROOT_CAUSES_2026-10-25.md`): seven data-store rows, each with 0 or 1 of its three runs clear of the noise, that the new key now counts. Three were faults in our own wiring, two were the test machine. The fixes were read in the store gate (`tools/store_gate.py`, `results/model_gate/STORE_GATE.md`) before they were committed. The gate's readings are our own model (evidence class S), never a benchmark result. Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

88.16.1 What changed

- **sysbench: the brain reads its own workload.** `status()` counted only `statement/sql/{select,update,insert,delete}`. sysbench sends prepared statements, which those counters never see, so the brain read 4.1 statements a second (the harness's own monitoring queries) while sysbench sent 999 to 4,198. The compass force and the verdict's work sample were the brain's own queries, and it resized the buffer pool blind, 10 to 23 times an arm. Now sysbench connects as its own account (`omni_load`, created by `--setup` with rights on `sbtest` only), and the brain reads that account's statements from the per-user summary table, prepared ones included (`statement/com/Execute`, `statement/sql/execute`, `execute_sql`, and the four plain ones). Every sysbench row, the GAIN rows included, stood on the blind reading and runs again on omni-v20.
- **Kafka: an extra consumer is handed back.** Above the operator's count, the hand-back needed a consumer whose 200 ms poll came back empty, which never happens with 8 round-robin partitions: a third consumer allowed after a load peak stayed 170 of 451 seconds and bought nothing. Now, above the operator's count, calm gives one consumer back while the backlog is within one poll round (50 messages a consumer), 30 s after the last change, because every change pauses the whole group. "Idle" is a full second with nothing consumed, and a consumer starts busy; no trial starts on the seconds before the producer begins (the $2 \to 1 \to 2$ double rebalance at the start of every arm is gone).
- **YCSB: the cache grows back below native.** Below the operator's size, nothing grew the cache on misses; a give-back trial allowed before the working set widened left two arms 64 MB short with misses at 1% or more for 435 of 457 seconds. Now, below native, the cache takes 64 MB a second back while misses are 1% or more, up to native's size, and an open give-back trial is abandoned. "Full" is WiredTiger's own 80%, or evicting in the last second (it was 90%, a level WiredTiger never holds). `serverStatus` is read in full once, then only for the sections the brain reads. mongod's CPU and the harness's are recorded apart, steal apart, beside the host's.
- **Redis: the CPU apart.** redis-server's, the App's, the brain's and the sampler's CPU are recorded apart, steal apart, beside the host's. The knob's rule is unchanged.
- **pgbench: the same state every arm.** Each arm starts from `pgbench -i` and a CHECKPOINT; the give-back waits 30 s after an add-back (5 s before); one aggregate line a second is kept from the per-transaction log. The workflow logs vmstat, iostat and PostgreSQL's checkpoints, lock waits and autovacuum into the run's files, so the runner's write stalls (6.2 s of schedule lag in a native arm far under capacity on the omni-v16 runs) can be told from the engine.
- **The readers.** `tools/omni_index.py`, `tools/ycsb_abc.py` and `tools/redis_abc.py` prefer the stack's own CPU where a run recorded it; older tables read as before (the index stays +3.397% on them).

88.16.2 The gate

The store gate replays every archived omni arm of the omni-v16 three-run tables, second by second, through omni-v19's wires and omni-v20's, each with its own verdict fed the recorded cost samples and its own knob, and reads the pair by the gauge's aim. It is open-loop: it shows what each wire decides on the same seconds, not how the store would have answered.

Wire	Arms	What omni-v20 does against omni-v19
Kafka	27	rebalances in the first 15 s 2.0 → 0, GAIN +100%; writes GAIN +92.9%; seconds below native while short GAIN +100%; seconds above native while calm (light) 37.6 → 6.3, GAIN +83.1% inside the arms' noise; consumers held +0.6%, inside the noise
YCSB	36	seconds below native while short 38.9 → 2.2, GAIN +94.4%; cache held power given +5.2%; writes power given +76.6%
pgbench	26	writes GAIN +21.0%; seconds below native while clients waited GAIN +12.7%; pool size =0.4%, under the floor
Redis	9,728 seconds	the two wires decide differently 0 times; the new CPU figures exist only in new runs
sysbench		the decisions cannot be replayed: the archived files hold only the old reading's counter (4.1 to 4.2 a second against sysbench's 999 to 4,198); a short real run reads the new one

No LOSS on any wire. The YCSB cache rise is a real change of behaviour: the new "full" opens the grow path on seconds that were slow, missing and evicting, which omni-v19 refused as "slow with room to spare". It is power given, and the replay cannot show what the extra memory buys; the real runs on omni-v20 read it. One pgbench arm (select, run C rep 3) is left out of the gate because omni-v19's own replay matched only 32% of its record there; every other arm reproduces its record in 97% or more of the seconds.

88.16.3 What runs again

Every benchmark runs again on omni-v20 (`scripts/reruns.txt`, the conductor's campaign from 13:24 UTC on 25 October), the data stores first in meaning: sysbench, Kafka, YCSB, Redis and pgbench. A fourth pgbench repetition, balancing the arm order against the runner's drift, is written as a proposed amendment in `docs/POSTGRES_PREREGISTRATION.md`, not yet in force. Tests: `tests/test_store_wires.py` (each check fails on omni-v19's runners and passes on omni-v20's) and `tests/test_store_gate.py`.

88.17 Omni v21: the immune system knows itself, knob by knob

Omni v21 (`OMNI_V21.json`, digest `b658f05d43c1e602`, 63 files) stood on main from the evening of 25 October to 30 October, when omni-v22 (`docs/OMNI_V22.md`, the data stores' wires at the max) landed on it; its tables stand as its own record. It is omni-v20 with the immune system's self-knowledge, the founder's order of 25 October:

> "OmniCompass's mechanism must know when something is redlining out of its band when OmniCompass is on it. And if OmniCompass couldn't fix it to stop it redlining, then OmniCompass's own mechanism must know that if native is better, then it switches itself to native. If native is not better, well, then it'll stay wherever and redline there, because redlining less with OmniCompass than something else is still a benefit ... against native ... This code and mechanism need to be built within the C++ harness, within the immune system ... The immune system has to be activated in nervous system to propagate."

88.17.1 The rule, in plain words

Term	What it is
Redlining	A knob Omni-Compass holds whose gauge is over its own line (the reading divided by the line is over 1) for three decisions in a row.
Stuck	Redlining, and Omni-Compass's own pushing has not brought it back: the knob is at its own limit, or the reading has not fallen by 5% of where the redline began.
Native is stronger	Native's twin, the same moment under native's own setting, reads lower than Omni-Compass by more than 5%.
Hand back	Stuck and native stronger: the knob goes to native and stays there 10 decisions, the hold doubling for each hand-back in a row (up to 160) and halving after a quiet hold.
Stay	Stuck and native not stronger: Omni-Compass keeps the knob and says so in its audit. It redlines less than native would, which is still a benefit against native.
Return	After the hold, Omni-Compass takes the knob back only when its own twin reads lower than native's by the same margin and nothing redlines with it.
The nervous system carries it	An organ every governed knob of which is handed to native has none of Omni-Compass's authority (`native_hold`) until it is returned.

All patents, copyrights and trademarks filed in the USA.

88.17.2 Where it is written

Place	What
`omnicompass/immune.py`	the rule, one knob at a time
`cpp/src/immune.cpp`, `cpp/include/omnicompass/immune.hpp`	its C++ twin, line for line, proven alike to the last bit on 200 seeded scripts (`tests/test_cpp_immune_parity.py`, sealed by `tools/seal.py`)
`omnicompass/nervous_system.py`, `cpp/src/nervous_system.cpp`	`native_hold`: the hand-back carried to the organ's authority, in both twins
`omni_controller/controller.py`	each service's autoscaler target: the response time over its line is the redline; native's twin is the same demand under the operator's target, the replicas native's own rule would ask and the M/M/1 wait they would give

omni-v19's immune rules come with it onto omni-v20: the hand-back on a pod that waits, the immune memory, native's line, immune maturity and the step back (`tests/test_immune_system.py`).

88.17.3 What the model gate read

The model gate against omni-v20 (`results/model_gate/V21_VS_V20.md`, eight seeds, every model, our own models, evidence class S): no LOSS against omni-v20 in any model.

Model	Against omni-v20
the cluster (the cloud's setting), at 60 s, at 15 s, with blinks, as shipped	pods waiting for a place down 12.9% to 13.3%, fewer waiting, GAIN; machine-hours up 0.9% to 1.3% and energy per core-hour up 0.8% to 1.0%, power given; the power cap's moves, reversals and travel down 1.3% to 1.4%, GAIN
the conveyance, its quota cases, the batch beside the service	every gauge the same as omni-v20, STEADY
the card, the card near its floor	every gauge the same as omni-v20, STEADY
the verdict	the same as omni-v20, STEADY

Against native the gate reads the LOSS rows omni-v18, omni-v19 and omni-v20 carry, none caused by this version and each on the next version's list: the pod start wait in the conveyance models (up 9.0% and 10.0%), the batch beside the service (requests served down 2.1%, alert minutes up 9.8%), and the card's 95th and 99th percentiles (up 0.9% to 5.8%).

Every benchmark runs again on omni-v21 from the moment it reaches main; nothing is read across engines.

88.18 Omni v22: the data stores' wires at the max, through each store's own account of a miss

Omni v22 (`OMNI_V22.json`, digest `0e23a0bc561b900a`, 65 files) stood on main from 30 October to 31 October, evening, when omni-v23 (`docs/OMNI_V23.md`) landed on it; its runs stand as its own record. It is omni-v21 with the five data stores' wires brought to the max, the founder's order of 30 October:

> "Anything that has a problem is what your job is ... find out why they went one way or the other and tweak it and turn it and tune it to the best possible way for an Omni Compass engine to interact with this as a system governor, convergence control core plane that it is ... bring to a solid A mechanism."

The store wires were written on 9 and 10 October with the brain's verdict judging every move under the resource objective, before the founder's order of 12 October that the max is the default brain, and were never brought to it. On omni-v21 they carried 33 of the 50 LOSS rows (`docs/LOSS_LEDGER.md`); their causes, read from the runs' own files, are on `docs/STORE_ROOT_CAUSES_2026-10-30.md`: the wall abandoned every spend trial and the fail-up was clamped to the allowance those trials never earned, so in 4,426 of the 4,581 seconds Redis stood over its line the brain asked for memory and was refused, and Kafka's hand-back gave back a consumer the load still needed.

88.18.1 The rule, in plain words

Term	What it is
The max on a store's knob	The wire's own rule asks; what it asks goes through unclamped, up to the operator's cover, never below native. The resource it takes (memory, consumers, servers) is power given, shown beside what it bought.
The store's own account of a miss	MySQL: the performance schema's timer on the data files' reads against the workload's statement timer. MongoDB: WiredTiger's time reading pages from disk for the application's threads against the server's own read latency. Redis: the application's own split of each request into hits and misses. Over the last 10 s, the misses' share of the service's own time.
The gate	Memory is spent only where that share is at least the one key's floor, a half of one percent (`tools/readings.py`): under it the misses are

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Term	What it is
	nothing the record could read, so memory could buy nothing it could read, and the knob holds and says why. Where the account is not read this second, nothing is known and nothing is taken.
The host's room	A notch is taken only while the host keeps 5% of its memory available after it (`/proc/meminfo`, the compass's cushion). Unread, nothing is taken.
The working set's floor	A hand-back never goes below the most memory the store held in the last 60 s (with the fullness margin, rounded up to a notch), nor below native: a knob handed back into its working set evicts what the service still asks for and buys it back at the store's price.
Kafka's twin and reflex	Each partition's arrivals (the topic's log-end offsets, once a second) placed on the members by the range assignor; a member's rate learned from the seconds the queue grew; the count goes at once to the smallest one that carries the arrivals and the backlog at nine tenths of a member's rate, never clamped; handed back in one move only to a count that carries the last minute's peak at seven tenths, 30 s after the last change; never below the operator's count; the immune hand-back to native when Omni-Compass's count redlines, stuck, and native's twin reads lower.
PostgreSQL's pool	A server added while clients wait is never clamped; the pool is never taken below the pooler's own setting.
The dial	`OMNI_DIAL=save` keeps omni-v21's loop on every wire (the tune-down, where giving the resource back is the aim); every record carries its dial.
The fingerprint	`tools/store_brain.py` (what the three cache wires share) and `tools/knob_verdict.py` (the tune-down's verdict) join it: no rule of the store wires changes without the version changing.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Term	What it is
The hand-back lands (the Kubernetes governor, the same version)	Every step of the governor's hand-back (the autoscalers' ranges and targets, the operator's own counts, every muscle's lever, the node pool) is tried 5 times against a transient failure of the cluster's API, 1 s apart doubling to 4 s, each on its own, and what did not land is raised and audited, never left silent. On 30 October (six-kube run 41044680505, repetition 346) one 500 from the API on the autoscaler list, at the reset, ended the whole hand-back on its first read: the conveyed CPU limits (1230m, 1850m) and the replica range (1 to 13) stayed behind and the arm was marked invalid. `omni_controller/controller.py` `_persist`, `omni_controller/muscles.py` `_guard_restore`, `RESTORE_TRIES`; `tests/test_restore_retry.py`.

What was tried and withdrawn: a slope of latency on miss share inside the arms as the price of a miss. It read 0.5 to 1.3 ms a unit of miss share on MySQL while the controlled comparison across pool sizes read none; the host's noise moves the misses and the latency together, and a regression reads that as a price. The root-cause page's first reading of the MySQL and MongoDB runs, that a miss cost the statement nothing, is withdrawn on the same page: the server's own meter, read on a machine of our own, puts the misses at 3% to 32% of what a statement waits for (a tuning-bench reading, class L on that host, no benchmark result).

88.18.2 Where it is written

Place	What
`tools/store_brain.py`	the working set's floor, the store's account of its misses, the gate, the host's room, the max's record
`tools/run_sysbench.py`, `tools/run_ycsb.py`, `tools/run_redis.py`	each cache wire's `Brain`: its own compass law and rule around the shared max; the server's account read each second; the attach check that stops a MongoDB run on a server without the account
`tools/run_kafka.py`	the group's twin, the reflex, the hold, the immune hand-back; the tune-down under the dial
`tools/run_pgbench.py`	the pool's `Brain`: never clamped upward, never below the pooler's own setting

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Place	What
`tools/knob_verdict.py`	the tune-down's verdict, now in the fingerprint; its summary reads the max's records
`omni_controller/controller.py`, `omni_controller/muscles.py`	the hand-back that lands: every step tried 5 times against the API's weather, each muscle on its own, what did not land raised
`tools/store_gate.py`	the store gate: every candidate replayed on omni-v21's archived seconds (class S)
`tools/kafka_model.py`, `tools/redis_model.py`	the two closed-loop models (class S), every input set from omni-v21's runs' own files
`docs/MYSQL_PREREGISTRATION.md` (amendment 6), `docs/YCSB_PREREGISTRATION.md` (6), `docs/POSTGRES_PREREGISTRATION.md` (4), `docs/REDIS_PREREGISTRATION.md` (5), `docs/KAFKA_PREREGISTRATION.md` (4)	declared before any run on them

88.18.3 What the model gate read

Our own models, evidence class S, never a benchmark result.

Gate	Against omni-v21
the store gate, every store wire's candidate on omni-v21's archived seconds, open-loop (`results/model_gate/V22_STORE_GATE.md`)	no LOSS on any wire or workload; the seconds below native fall to none on every wire (MySQL 97.9 → 0 an arm, MongoDB 12.5 → 0, Redis 36.6 → 0, PostgreSQL 223.5 → 0); the three cache candidates hold at native in the replay because omni-v21's audits carry neither the stores' accounts nor the host's memory; the pooler's servers +28.2% and Kafka's consumers +130.6%, power given
the Redis cache, closed loop (`results/model_gate/V22_REDIS_MODEL.md`)	work inside the line GAIN in every workload (up 7.7% to 22.9%), the mean latency GAIN (down 36% to 59%), the 95th and 99th percentiles GAIN or STEADY, the memory held power given (201 to 304 MB against 62 to 66 MB); no LOSS

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Gate	Against omni-v21
the Kafka group, closed loop, 30 s a notch, the development seeds 101 to 108 (`results/model_gate/V22_KAFKA_MODEL.md`) and the untouched seeds 201 to 208 (`…_UNTOUCHED.md`)	no LOSS row; work inside the line GAIN, the 95th and 99th percentiles GAIN, the most messages waiting at once GAIN, consumers power given
the Kafka group at 20 s a notch (run C's setting, not the counted one; `…_20S.md`)	one LOSS row: the burst's most messages waiting at once, up 30.6% inside the seeds' spread (native's queue grows about 1,100 messages in a 20 s notch and one rebalance costs about the same); on the next version's list with its cause
the Kubernetes governor's models (`results/model_gate/V22_VS_V21.md`, `tools/model_gate.py`)	omni-v22's one change to the governor, the hand-back tried five times against the API's weather, moves no decision: every model reads omni-v21's own numbers on every gauge, STEADY, identical

MySQL's and MongoDB's accounts of a miss are read for real on the first runs of omni-v22 (omni-v21's audits do not carry them), and a closed-loop model of each store, set from those runs' own files, is the next model gate's work.

Every benchmark runs again on omni-v22 from the moment it reaches main; nothing is read across engines. The store benchmarks run first, every table at the counted 30 s a notch (`scripts/reruns.txt`).

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

88.19 Omni v23: Omni direct keeps every muscle Omni-Compass cannot be: a knob whose writes are refused goes back to native's own controller

Omni v23 (`OMNI_V23.json`, digest `c96ea4105d8747db`, 65 files) stood on main from 31 October, evening, to 1 November, night, when omni-v24 (`docs/OMNI_V24.md`, the factory beat for its place) landed on it; its runs stand as its own record. It is omni-v22 with one guard in the Kubernetes governor's pod muscle of its own (`omni_controller/controller.py`, `_own_pods` and `_own_refused`), on the founder's order of 31 October, given on reading that the arm by itself had read like native:

> "Omni direct is directly to muscles, but Omni direct still might need an autoscaler like Kubernetes ... we still might need a muscle or two we're using. We're going straight into all the muscles as the brain and orchestrator, scheduler and all that, but what Omni-Compass can't do and needs the muscle for has to be achieved even in direct, so that it can work and do everything else ... Don't just embed some shit and fail

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

> the whole system because we don't have the muscle to do something ... any muscle that we don't have, Omni-Compass cannot be it: it has to be there, if that's Kubernetes or whatever."

64 of its 65 files are omni-v22's bytes. No gain, preset, card or law moves; do no harm keeps its strictest form.

What "direct" can and cannot mean (the founder's analysis, the same day: "Omni-Compass would have to become the Kubernetes mechanism to be what's considered direct"). On a Kubernetes stack Omni-Compass is a brain with no organs: Kubernetes' scheduler places every pod and the kubelet runs every container, in every arm. The arm by itself there is Omni-Compass's own pod rule in place of the autoscaler's arithmetic and nothing else, so it is never called direct; it is a mechanism test kept in the record, not a product arm, and the product has two sides, native and Omni-Compass on native (the founder's order of 25 October). The one test where the word holds is the orchestrator showing without Kubernetes (`docs/OMNI_ORCHESTRATOR.md`), where Omni-Compass's own small orchestrator is the organs; its three arms read, run by run: Omni-Compass on native the strongest in all three (the most work, the fastest response in two, fewer machines in all), native the weakest, the arm by itself between them (level with Omni-Compass on native in run A, behind it in B and C). This guard serves every arm: wherever Omni-Compass's own rule cannot move a knob, the organ that can gets it back.

88.19.1 What was found

Every arm by itself run on kind from omni-v19 (24 October) to omni-v22 had the governor's pod writes refused by the rig's own identity: `kubectl scale` patches the scale subresource, `deployments/scale`, a resource of its own under Kubernetes' RBAC, and the rig's role granted `patch` on `deployments` by name and never the subresource. Fifteen of fifteen decisions a window ended Forbidden, in every repetition; the workload stayed at the operator's count; the machine and conveyance muscles wrote as always, so the window's no-write check never fired. omni-v21's three runs of the entry were admitted and are read in no table; omni-v22's two were marked invalid by a second rig fault. Both rig faults are fixed (`docs/SOLO_PREREGISTRATION.md`, amendment 1). What the engine lacked is this version: when Omni-Compass cannot be a knob's muscle, the knob must go back to the muscle that can, so the organism never runs with a knob nobody moves (amendment 2, the founder's order above).

88.19.2 What changes in the engine

- A write of a workload's own scale that the cluster refuses (its permission, its admission, its API) is recorded in the audit (`own_replicas`, `refused` n, the cluster's words) and the decision goes on; the cluster keeps the last count that landed. Before omni-v23 the exception ended the decision (`decision failed (n in a row)`) and nothing else happened, decision after decision.
- At `OWN_REFUSALS` (3) refusals in a row Omni-Compass cannot be that knob's muscle: it makes native's own pod autoscaler from the operator's own target and range recorded on the workload (`kubectl autoscale deployment NAME --cpu-percent=T --min=lo --max=hi`; with no range recorded, from one to ten times the operator's count), audits the hand-back (`handed_back`, `after_refusals`, `target`, `range`), and leaves the workload to it for the rest of the run: the

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

snapshot's governed set holds it from the next decision on, and the reset leaves native's autoscaler standing. A hand-back the cluster refuses too is audited (`hand_back_refused`) and tried at the next refusal.

- A write that lands ends the run of refusals.
- Every other arm is untouched: Omni-Compass on native never removes native's controller, so a refused write there leaves native's own controller moving the knob as before; the machines, the conveyance, the power cap and the batch muscles are omni-v22's bytes.

88.19.3 What changes in the rig, not the engine

The kind identity (`deploy/kind/rbac-omni.yaml`) gains `create` on `horizontalpodautoscalers` in the default namespace, for the hand-back alone, and the preflight proves it; a window of the arm by itself in which the knob was handed back is refused as a result of that arm (the organism was kept whole, but Omni-Compass did not run the arm by itself): `INVALID RUN: by itself, the knob ... was handed back to native's own autoscaler`. `tests/test_kind_rig_rbac.py` fails a rig without either.

88.19.4 The model gate

`results/model_gate/V23_VS_V22.md` (class S, our own models; `tools/model_gate.py`, seeds 1 to 8, the engine that stood, omni-v22, the candidate omni-v23): every one of the 95 gauge rows of the 11 models reads identical on every seed, the counts identical, no LOSS. No model refuses a write of the cluster, so the guard never fires in the models and the candidate reads identical to omni-v22 on every gauge; its proof is the tests below and the arm's own files when the entry runs again.

88.19.5 The tests

`tests/test_own_replicas.py`, `HandBack`: a cluster that refuses the scale write three times in a row gets native's own autoscaler at the operator's 50% target and 1 to 10 range, the muscle writes nothing more to that workload, the count the cluster kept stands (never a knob nobody moves); a write that lands after two refusals ends the run of refusals and no autoscaler is made; with no range recorded the autoscaler's ceiling is ten times the operator's count. The unit-test suite, the function tests and the release check pass on the tree; no C++ twin changes (the Kubernetes governor has none).

88.19.6 What is run again

Every benchmark runs again on omni-v23 from 20:00 UTC on 31 October 2026 (`scripts/reruns.txt`, A of every entry, then B, then C; the conductor's campaign, `scripts/dispatch_grid.py`). The omni-v22 runs started before that moment run to their end as omni-v22's record; nothing is cancelled. The entry `kubernetes by itself` runs on the rig as amended, three arms, its table kept in the record and not carried on the front page (the founder's order of 25 October).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

88.20 Omni v24: the factory beat for its place: a decision every 10 s on site, every 60 s through a cloud

Omni v24 (`OMNI_V24.json`, digest `66c8f2d94b3e4725`, 65 files) stood on main from 1 November, night, to 3 November, night, when omni-v25 (`docs/OMNI_V25.md`, the Kafka wire's producer started before the governor's thread) took its place. It is omni-v23 with one change in the Kubernetes governor (`omni_controller/controller.py`, `factory_beat`): the heartbeat it ships with, its full decision, is read from the place it runs in, a decision every 10 s on site and every 60 s through a cloud. On the founder's orders:

> "Whatever is the best one out of all that helps the best system is the factory set one." (23 October) "60 seconds is a disadvantage, it's not a benefit ... we have to have the basic line engine tuned to what we call the basic setting, and then we lock that, and anybody can turn and tweak it to another scenario." (31 October) "You pick and find out." (31 October, night) "Update, push, build, wire, and give me my new version engine and everything." (1 November)

64 of its 65 files are omni-v23's bytes. No gain, guard, preset, card or law moves; do no harm keeps its strictest form. Every rule of the governor counts seconds (omni-v16), so the beat changes only how often the governor looks, never how long any rule waits; the fast checks (the scheduling floor, the pod reflex, the conveyance's clock) stay every 5 s at every beat.

88.20.1 What changes in the engine

- With no `--interval` set, the governor reads the cluster's nodes once, at its start. A node whose `spec.providerID` names a public cloud's machine (`azure://`, `gce://`, `aws://`, `oci://`, `digitalocean://`, `linode://`, `ibm://`, `alicloud://`, `hcloud://`, `scaleway://`, `vultr://`) makes the place "through the cloud", and the beat is 60 s. Every other node (kind's `kind://`, the owner's own machines, a private cloud the owner runs, a node with no providerID) makes it "on site", and the beat is 10 s. A reading that fails, or finds no node, keeps the longer beat, 60 s: a blind reading decides nothing (omni-v11).
- `--interval` set by hand always wins. The heartbeat stays a dial (any beat from 5 to 120 s; the live engine's six buttons, 10, 15, 30, 60, 90 and 120 s), and every beat a person sets is that person's tune, its results its own.
- The audit's first record names the place, the beat and the reason (`factory_beat`), so every run says which beat it ran at and why.
- `--print-factory-beat` prints the beat for the cluster the kubectl reaches and exits. Every rig asks the engine through it (`scripts/factory_beat.sh`), so the rule is written once, in the engine.

88.20.2 Why these two beats: the pick, before the gate

The rule that picks the factory beat was frozen before any reading was seen (`docs/PACE_PREREGISTRATION.md`, amendment 4): a beat is admissible when no gauge reads LOSS against native (in a cloud the machine-hours stand for the bill and may not rise); among the admissible beats the factory beat is the one no other dominates on the service gauges; where none is admissible the factory beat stays 60 s. Amendment 6 read the twelve beats, 5 to 120 s, again on the corrected model (its stand-in cluster gives every pod its own object and metadata), in both places, on the tune study's development seeds 101 to 108, one day each (our own models, evidence class S; the record `results/model_gate/V23_LADDER_CORRECTED.md`, written by `tools/beat_ladder.py` from its source report `results/model_gate/V23_LADDER_CORRECTED_SOURCE.json`, which names the tree each place ran on):

- **On site** (the kind rig's own machines, made at the start, no cluster autoscaler): every beat admissible, and 10 s the one beat no other dominates (rule 2). Against 60 s at 10 s: the minutes over the response line down 65.5%, from 6.9 to 2.4 a day (fewer, GAIN); the 95th percentile response down 9.9%, from 59.3 to 53.4 ms (faster, GAIN); the pod autoscaler short of its target down 6.2% (GAIN); the power-cap request's moves down 47.2% and its reversals down 53.1% (GAIN); the machine-hours identical (on site the machines are already made and paid for). What it costs: the governor reads the cluster 6,897 times an hour where it read 2,317 (up 197.7%, power given), and its own processor works 10.3 s an hour where it worked 1.3 s (power given).
- **Through a cloud** (the plant with the cloud's own autoscaler, Omni-Compass at the max on top): no beat admissible. Every beat raised the machine-hours against native, up 7.8% to 33.7% (up 14.7% at 60 s): the bill, which the rule does not let rise in a cloud; and every beat but 90 s raised the pods waiting for a place (LOSS, up 15.4% at 60 s). By rule 4 the factory beat stays 60 s, and those rows go on the next version's list with their cause: the autoscaler target held ahead of the load buys machines the cloud bills, and a pod waits while the cloud makes a machine (the next design: ask the cloud for a machine without making a real pod wait).

88.20.3 The model gate

`results/model_gate/V24_VS_V23.md` (our own models, evidence class S; `tools/model_gate.py`, seeds 1 to 8, one day each, the engine that stood, omni-v23, against the candidate, omni-v24): no LOSS against omni-v23 in any model. Eleven of the twelve models read identical on every gauge and every seed (the verdict model among them): every model that sets its own beat, and the shipped cloud model (`cluster_shipped`), where both engines decide every 60 s because the model's nodes are a cloud's machines.

The new on-site model (`onsite_shipped`: each engine at its own default beat on the kind rig's own machines, no cluster autoscaler, the 5 s plant) is the preregistered reading of the pick on the untouched seeds (amendment 4: omni-v23 at its shipped 60 s against the pick; the same seeds, plant and beats as `--pace-periods 60,10`). omni-v24 at its 10 s against omni-v23 at its 60 s:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- the minutes over the response line down 60.7%, from 7.0 to 2.8 a day (fewer, GAIN);
- the 95th percentile response down 8.2%, from 61.0 to 56.0 ms (faster, GAIN);
- the pod autoscaler short of its target down 5.1% (GAIN);
- the power-cap request's moves down 53.3% and its reversals down 58.5% (GAIN);
- the machine-hours identical; no pod waited for a place in either engine; no error, no held reading, and no trial abandoned (omni-v23 abandoned 6).

Against native on site, omni-v24: the minutes over the line down 89.8%, the 95th percentile down 29.7%, the autoscaler's shortfall down 10.4% (GAIN), the machines the same. What it costs: the governor reads the cluster 6,079 times an hour where omni-v23 read 2,131, and its own processor works 10.7 s an hour where it worked 1.3 s (power given).

The rows that read LOSS against native in the cloud and card models (pods waiting for a place, a pod's start wait, the batch's requests and minutes over the line, the card's 95th percentile) are omni-v23's own, identical seed for seed on omni-v24: the beat does not reach them. Each stays on the next version's list with its cause (`docs/CHANGE_CONTROL.md`).

88.20.4 The tests

`tests/test_pace_clocks.py`, `test_the_factory_beat_is_the_places`: a cluster of kind nodes gets 10 s; nodes of Azure, Google and Amazon get 60 s; nodes with no providerID get 10 s; a reading that fails, or finds no node, gets 60 s; a beat set by hand is kept; the install files set no beat. `tests/test_cloud_cadence.py`: every cloud rig's beat is 60 s. The unit-test suite, the function tests and the release check pass on the tree; no C++ twin changes (the Kubernetes governor has none).

88.20.5 What changes in the rigs and the install files, not the engine

- The kind rigs ask the engine for the beat (`scripts/kind_bench.sh`, `kind_full.sh`, `kind_pilot.sh`, `pilot_shadow.sh`), so a kind run decides every 10 s and a managed cluster's run (Azure) every 60 s; each run writes its beat beside its files (`omni_interval.txt`), as every run has since omni-v16. The pace arms of `scripts/kind_paired.sh` still set their own beat; the robustness test's second governor reads the first one's beat from the run's own file (`scripts/kind_robust.sh`); the levers' mechanism proof keeps the 60 s beat its checks were written at, set by hand (`scripts/kind_levers.sh`).
- The install files set no beat (`deploy/install/omni-compass.yaml`, `omni-compass-cloud.yaml`, `deploy/controller.yaml`), so an installed governor reads its own place.
- `tools/model_gate.py`: the model's stand-in nodes carry a providerID as a real cluster's do (a cloud's machine in the cloud setting, kind's elsewhere), and the gate reads a new model, `onsite_shipped`: each checkout at its own default beat on site, on the 5 s plant.
- `tools/live_reps.py`: a run without its beat file is older than omni-v16 and is read at the 60 s it ran at.

88.20.6 What is run again

Every benchmark runs again on omni-v24 from 01:30 UTC on 2 November 2026 (`scripts/reruns.txt`, A of every entry, then B, then C; the conductor's campaign, `scripts/dispatch_grid.py`). The omni-v23 runs started before that moment run to their end as omni-v23's record; nothing is cancelled. On kind, which is on site, the compass arm decides every 10 s; on Azure, through the cloud, every 60 s, as on omni-v23. The real runs of the pace preregistration (amendment 3's arms) read the factory beat beside the dial's other beats. The card governor on the chips (`omni_controller/gpu_governor.py`) keeps its own clock and is unchanged.

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

88.21 Omni v25: the Kafka wire's producer started before the governor's thread; a stalled producer stops its workload, never the job's clock

Omni v25 (`OMNI_V25.json`, digest `cf56fc0a7b707452`, 65 files) stood on main from 3 November, night, to 7 November, when omni-v26 (`docs/OMNI_V26.md`, another workload's waiting pods hold native's target) took its place. It is omni-v24 with one fault fixed in the Kafka wire (`tools/run_kafka.py`, one of the eight runners in the fingerprint since omni-v15) and one comment corrected in the Kubernetes governor (`omni_controller/controller.py`). No rule, gain, guard, preset, card or law moves; do no harm keeps its strictest form; the governor's decisions are byte for byte omni-v24's. On the founder's standing order that every fault found is fixed and lands as the next version, told, not asked, and his order of 3 November ("go into the GitHub ... grade and see where it's at ... keep pushing").

88.21.1 The fault

From omni-v22 (30 October) no Kafka run on GitHub finished. Every workload's job ran to its 150-minute limit inside "Run the workload, native and omni" and handed in nothing; from 2 November, 20:03 UTC, 16 runs in a row ended so (runs 168 to 183 of the `kafka` workflow; run 41601163807 is one), where omni-v21's took 14 to 32 minutes a workload (run 40400868003). The job's own log could not say where it stood: the runner wrote its progress only to a file the job uploads.

Reproduced here on Kafka 3.9.1 as the workflow installs it (one KRaft broker, `kafka-python-ng`; the light workload, one repetition, 5 s a notch): the native arm finished; in the omni arm the producer process was single-threaded and waiting on a futex, before it had opened its log or sent a message, the main process waited on it, and the governor's audit read no arrivals for 540 s, when the load lasts 75 s.

The cause: a fork copies only the thread that calls it. From omni-v22 the governor's thread opens its own Kafka client at its start (the reader of each partition's arrivals, `Offsets`, the twin's input), while the main thread forks the producer an instant later. A lock that thread holds at that instant (its first import of the client,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

its first connection) stays held in the child for ever, and the producer blocked on it. The native arm has no governor's thread, so it never stalled, and omni-v21's governor opened no client of its own, so it never stalled either.

88.21.2 What changes

- The producer is forked before the governor's thread starts (`run_arm`); the Kafka client is loaded once, in the main thread, before any thread or child starts (`run_workload`).
- A producer still running 120 s past its own schedule is stopped and its workload fails with the reason (`join_producer`, `PRODUCER_GRACE_S`), in the arms and in the capacity reading, so a stalled child can never again hold a job to its time limit.
- The governor's decisions are untouched: 53 of the wire's 58 definitions are byte-identical to omni-v24's, the brain (`Brain`), its twin (`RateTwin`), the decision rule (`decide`), the governor's loop (`Omni`), the arrivals' reader (`Offsets`), the group, the producer and the consumers among them; the three that change (`run_arm`, `capacity`, `run_workload`) start and wait on processes, and the two added (`join_producer`, `PRODUCER_GRACE_S`) bound that wait.
- `omni_controller/controller.py`: a comment named the omni-v23 ladder's file (`V23_LADDER.md`, read on the model's faulty stand-in) where it means the corrected one (`V23_LADDER_CORRECTED.md`); no statement moves.

Outside the engine, with it: `.github/workflows/kafka.yml` prints the runner's progress into the job's log as it runs, so a stall shows where it stands.

88.21.3 The model gate

The model gate against omni-v24 (`results/model_gate/V25_VS_V24.md`, class S, our own models; `tools/model_gate.py`, seeds 1 to 8, the standing engine omni-v24 and the candidate this tree): all twelve models identical to omni-v24 on every gauge and every seed, 104 readings and none different, so no LOSS against omni-v24. The Kubernetes governor's one change is a comment. The Kafka wire's decisions are the same code as omni-v24's (53 of its 58 definitions byte-identical, every one the governor decides with), and what changed (when its processes start, how long the main thread waits on the producer) is not a decision any model or replay of the archived seconds reads; the closed-loop Kafka model (`tools/kafka_model.py`) gates a change in the decisions against the omni-v21 loop and has nothing to read here.

The same light workload on the candidate, on the same broker: both arms finished, the omni arm's every message consumed and every consumer handed back at its end (a check of the repair on one repetition, not a benchmark result).

88.21.4 What is run again

Every benchmark runs again on omni-v25 from 21:00 UTC on 3 November 2026 (`scripts/reruns.txt`, A of every entry, then B, then C; the conductor's campaign, `scripts/dispatch_grid.py`), Kafka

All patents, copyrights and trademarks filed in the USA.

among them for the first time since omni-v21. The omni-v24 runs started before that moment run to their end as omni-v24's record; nothing is cancelled.

Run and scored by Dubra Software Inc. / The Omni-Compass LLC's own code. No outside party has reviewed or approved these results.

CHAPTER 89

History

Earlier states of play, kept whole. Nothing here is current status; the current state is `docs/STATE_OF_PLAY.md`.

89.1 State of play as written on 27 September 2026 (with the update of 28 September)

Superseded for live results. The live evidence below predates sets 19 and 20. The current live table is `results/live/LIVE_PAIRED.md`; energy on kind is a declared model, not a meter. The first metered test is `scripts/gpu_paired.sh` (`docs/GPU_BENCH.md`).

Update, 28 September 2026. Added since this page was written, each with its evidence: - **Live, set 21** (conveyance only when response time needs it): p95 -37%, machines in service -21%, CPU used +26% (unchanged from set 20; its source is still open). `results/live/LIVE_REPS_21.md`. - **GPU governor bounded** (0.70 share floor, busy gate, 2 s decisions): on the MLPerf-calibrated modelled card, +5.1% and +1.3% work per kJ with p95 within +10% (the old governor failed that guardrail at +31% and +66%). Model only. `results/gpu/sim/`. - **Speed lock** (opt-in): speed won elsewhere spent on GPU watts, every gauge kept at least 1% faster than without Omni. Model only. `results/gpu/sim/pipeline/`. - **CPU and GPU on one conserved power budget** (conveyance law over CPU and GPU organs): +1.4% to +5.7% work served against today's fixed caps, never over the site budget. Model only. `docs/CONVEYANCE_LAW.md`, `results/hardware/NODE_EXCHANGE_*.json`. - **The manual in the box:** `docs/INTEGRATION_MANUAL.md`; every gauge: `docs/METRICS_CATALOG.md`; against what runs today: `docs/COMPARISON.md`.

This is the whole repository at the commit named in `STATE_OF_PLAY_COMMIT.txt`. Everything below can be rerun from it.

Run it live on real Kubernetes yourself: on any machine with Docker, kind, kubectl and Python, run `bash RUN_LIVE.sh 3`. It builds a fresh 7-node cluster per arm, runs native, Omni on top and Omni alone, and

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

writes `live_runs/LIVE_REPS.md`. GitHub Actions runs the same comparison with a pushed commit whose message contains `[reps]`.

Rerun the whole thing: `pip install -r requirements.txt && python verify.py`. It must end `VERIFICATION: PASS`, and it does at this commit.

89.2 Best measured results, and where each one comes from

Claim	Evidence	Where
B (Omni on top of each platform): 0 losing cells on held-out scenarios; strictly GAIN on 27 of 28 platform-workload pairs	simulation, pre-registered	`tuning/B_FIX.json`, `tuning/B_TONE_HELDOUT.json`
Four-cluster sites: B 0 losses on all 7 platforms; C 0 losses vs GKE, AKS/Karpenter, CAST AI, Spot	simulation, held-out	`tuning/SITE_LEAGUE.json`
C (Omni alone), one global setting, 400 never-used scenarios: 153 toward their aims / 174 equal / 37 LOSS or power given of 364 cells (Holm-corrected)	simulation, held-out	`tuning/CONFIRMATORY.json`
C with nervous-system coordination, 400 fresh scenarios: 151 / 173 / 40	simulation, held-out	`tuning/CONFIRMATORY_COORD.json`
Controllers fighting each other: lowest of all 8 systems on web (0.07 per day) and four-cluster sites (0.56 per day)	simulation, held-out	same file
Real demand, 1,052 recorded PlanetLab machines: 0 losing cells of 91	simulation on real traces	`tuning/PLANETLAB_LEAGUE.json`
Faults (machines dying, spikes, crash loops, noisy neighbours): fewest pages to a human, fastest recovery	simulation, 500 runs per workload	`results/protocol/`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

Claim	Evidence	Where
GPU power law (engine cap over the MLPerf-measured performance law), against native at equal work: energy -27% to -33%, time over the heat limit -73% to -78%	simulation, held-out	`results/hardware/SUMMARY_HELDOUT.json`
Site power exchange (conveyance law, manuscript Ch. 29-31): 4 GPU groups under one site budget: 0 minutes over the site limit at 70/60/50% budgets (native 10.5/45.6/106); least energy at every budget; 31-115 fewer backlog minutes than the static split	simulation, held-out; law proved (conservation, Lyapunov, exponential convergence)	`docs/CONVEYANCE_LAW.md`, `results/hardware/SITE_EXCHANGE_HELDOUT_*.json`
Same-tower OFF / observe / ON receipt: observe identical to OFF; ON ahead of the graded-reflex comparison build on healthy time, recovery, energy, violations and peak power (peak below OFF)	simulation, held-out	`results/tower_off_on/`, `results/external_review/CHATGPT2_REVIEW.md`
Live levers under the nervous system: 19 of 19 checks on real Kubernetes; reset restores everything	live, kind	`results/live/LIVE_LEVERS_2_NERVOUS.txt`
Shadow pilot kit: a read-only identity made 0 writes across 40 decisions	live, kind	`results/live/LIVE_SHADOW_1.txt`
Safety shield: 2,000,000 adversarial cases, 0 violations (the test found 2 real bugs, both fixed); C++ twin matches	test	`tests/test_shield_properties.py`
C++ engine: 100,000,000 decisions, no failures, about 2.3 µs per decision	test	`results/SOAK.json`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

89.3 What still loses, measured

- **C, typical response time, web and four-cluster:** about 20% slower than every platform. Omni fills pods to 80%, where the others stop at 70%, and trades response time for energy.
- **C, machine starts and stops:** loses to plain Kubernetes and OpenShift, which hold machines steady and pay for it in machine-hours.
- **C, GPU and batch:** energy 1-2% lower and power and heat margins 1-4% lower than the tight packers (AKS/Karpenter, CAST AI, Spot).
- **Live, set 3, with a working probe:**
  - Omni kept all 6 machines. Latency near the 500 ms SLO blocks machine release.
  - There is no significant difference from native on anything else, except that C has more waiting pods.
  - The earlier live machine savings (sets 1-2) are withdrawn, because the broken probe had blinded the latency sense (`results/live/LIVE_REPS_PROBE_DEFECT.md`).
  - Set 4's decision trail showed why. Latency spikes from pod saturation at load steps kept the service from being clean, and the engine's calm stayed under the machine threshold (0.65 against 0.7). Both are addressed by the attribution gate and the two-way wiring above; the live test is pending (`results/live/LIVE_REPS_4_DIAGNOSIS.md`).
- **A bound, not a loss:** no controller, even one with perfect foresight, can match both the tightest packer's machine-hours and the calmest autoscaler's churn at once (`tuning/bound.py`).

89.4 Two-way nervous system (new, live test pending)

Manuscript Appendix J names delay and dropout handling and feedback interpretation as the nervous system's job. The live controller now wires both directions (`docs/TWO_WAY_NERVOUS_SYSTEM.md`).

- **Blind senses are detected against the wall clock.** A hung probe was the root cause of the live set 1-2 error.
  - A blind sense feeds the engine's `stale` channel.
  - It blocks every give-back.
- **Commands are read back.** Drift feeds the engine's `drift_ratio`. No new machine release goes out before the last one has landed.
- **The machine organ has its own engine view and a release gate.** Pods move first, and the headroom proof uses the engine's rho.

Tests: 75,000 blind states, 200,000 gate states, 300,000 nervous-system states.

Live sets 5 and 6 could not run. From 03:51 UTC GitHub refused every job, including `verify`: runner ID 0, no steps, failed within about 2 seconds. That is GitHub declining to start runners, which on a private repository is most often exhausted Actions minutes or a spending limit. It is not a code failure. `python verify.py` passes locally at this commit.

89.5 Map

Path	What it is
`omnicompass/core.py`, `cpp/`	six-state engine; C++ twin
`omnicompass/closure.py`	closure law: forward projection, boundary correction, turning point, muscle tone
`omnicompass/nervous_system.py`	one engine state grants each organ its authority and envelope
`omnicompass/shield.py`	safety shield, downstream of everything
`omni_controller/`	live Kubernetes controller and levers
`fleet/`, `hardware/`	simulation plants
`tuning/`	benchmarks, pre-registrations, results
`results/live/`	every live run, including the failed and withdrawn ones
`docs/history/OMNICOMPASS_BUYER_EDITION.md`	the buyer-facing report
`docs/history/CONSENSUS_AUDIT.md`	the five-reviewer audit (written inside the project; internal, not independent)

89.6 The state of play as it stood on 2026-10-10 (Omni v3), moved whole on 2026-10-16

Kept as its own page, `docs/history/STATE_OF_PLAY_2026-10-10.md`: the 10 October narrative, every number Omni v3's, named as such.

89.7 The state of play as it stood on 2026-10-06 (moved here whole on 2026-10-07)

89.8 In one paragraph (2026-10-06, Omni v1)

Omni v1, the same in all three of our runs. On real Kubernetes, every test ran three times as separate GitHub runs on the frozen engine, ten pairs each (`docs/OMNI_V1.md`, the six `results/live/V1_*.md` tables). Work inside the response line **up 42% to 48%** in all three runs of the all-four test (18.6 → 27.6 requests a second in run A): more work, GAIN in all three of our runs; the 95th percentile **down 56% to 69%** in every run of the steady, wandering, all-four and fault tests: faster answers, GAIN in all three of our runs; failed requests down 12% to 13% where load swings, GAIN in all three of our runs; machines down 1.5% to 3.4% at steady load and down 15% to 24% on the batch queue, a cut, GAIN in all three of our runs, no difference beyond the noise elsewhere; energy a declared model (kind never powers a

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

machine down); beside a noisy neighbour, no difference beyond the noise on every row. **The Omni index on v1** read real Kubernetes alone (only rows the same in all three of our runs counted, a row inside the noise as zero; Azure and the card were to join when their v1 runs landed); its figure of that day is not kept in the tree, so it is not repeated here (the index of record is omni-v25's, `results/OMNI_INDEX.md`). The paragraph below is the earlier engine's reading, kept as the record it was.

Omni-Compass sits on top of Kubernetes and hardware and gets more out of what is already there. On real Kubernetes, the engine before v1 (the live controller at rules 1-8, commit `353903683009`), ten pairs per test, native against compass with the same work sent to both: **41.7% more work handled inside the response line on the same machines** (capacity, all four in one run), responses **59-64% faster** at the 95th percentile (steady, wandering, all four, faults), 12% fewer failed requests where load swings, energy equal or lower, and not one pod left without a machine. Machines: up to 2% fewer. Omni gives a machine back only when a paired trial shows the service no slower without it, and on these clusters one machine fewer made requests 30-45% slower in most trials, so it kept them and spent them on speed and work (earlier engines without that check parked 29-36%: `docs/history/`). All of it together, real software on real computers (the software end, not bare metal and not the chip): **12.9%, GAIN, by that engine's own index** (kept whole in `docs/history/OMNI_INDEX_pre_v1.md`; the index of record is omni-v25's, `results/OMNI_INDEX.md`).

Omni v1 (`docs/OMNI_V1.md`): the engine is frozen and fingerprinted (`OMNI_V1.json`), and every test above runs three times on it, as separate GitHub runs (A the result, B and C the replications); each table reads GAIN in all three of our runs, LOSS in all three of our runs, no difference beyond the noise, or the runs disagree, and replaces the earlier engine's table as it lands. Running on v1 now: the Kubernetes suite three times, the batch test, the six organisms at 1, 10, 100 and 1,000 copies with the real cluster inside, the big organisms on rented Azure machines, the Azure steady and burst bill tests, CityLearn, and the power grid.

What is shown and what is not. Shown: more work inside the response line on the same machines (34-52% across the three capacity runs on earlier engines) and a faster tail, on real Kubernetes. Not yet shown: an energy or cloud-bill saving on real machines. On kind the machines are containers on one runner, so a machine out of service saves modelled watts, not a metered bill, and Azure's bill did not move on the earlier engine (`results/live/AKS_BILL.md`); the v1 Azure runs are the test of that. The current card governor has not run on a real GPU.

The card: the first real run (NVIDIA A10, 2026-10-02) used a card controller since replaced; it is not a result to stand on. In simulation the current controller (amendment 12) is clearly faster under an operator's power cap (p95 6-7% faster, time over the line 1 point lower) and saves 0.5-3.7% energy on the card's own firmware with p95 even (`results/sim/gpu_two_wire/`). The real card runs next: one card, the card inside the six organisms, then eight cards.

The 945 muscles (Omni v2; 656 in v1) are models of real control systems. With the real cluster or the real card inside, they show the mechanism (work the same, energy 0.1-0.2% lower, time over the line lower than native in every organism); they are never counted in the headline.

All patents, copyrights and trademarks filed in the USA.

Test (real)	Work	Speed	Machines	Energy	Source
All four in one run: load up and down one step at a time, 10 pairs	**+29%**	p95 -62%	**-3.6%**	-0.3%	`results/live/ALL_FOUR.md`
Capacity, load rising, 10 pairs	**+48%**	p95 -50%	-1%	-0.3%	`results/live/AMENDMENT_3_RUNS.md`
Sets 22-27, same work, 10 pairs each	same, none failed	p95 -55% to -65%	**-29% to -36%**	-0.1% to -0.5%	`results/live/LIVE_REPS_22.md` to `results/live/LIVE_REPS_27.md`
Six organisms, cluster inside, 5 pairs each	requests served +0.5% to +6%	p95 -24% to -40%	same to -2%	-0.1% to -0.6%	`results/live/SIX_KUBE.md`
Azure AKS, steady load, 5 pairs	same	p95 -20%	same	(billed) same	`results/live/AKS_BILL.md`

All four in one run is done: every one a proven GAIN in the same run (`results/live/ALL_FOUR.md`). Running now: demand that wanders (up, spike, down, back up, idle, 10 pairs), the Azure burst bill test, and the 1,000-copy grid of the six organisms on Lambda.

89.8.1 The engine now, and what runs on it (2026-10-05)

The live controller is frozen at rules 1-8 (`docs/K8S_COMPASS_PREREGISTRATION.md`, amendments 1-8): rules 5-8 were added today (a pinned gauge is not a steady demand; coasting; cruise; the emergency brake). Every result above was measured on an earlier version of the controller, and each names its commit. So that every number comes from one engine, the whole Kubernetes suite runs again on the frozen engine: all four in one run, demand that wanders, the steady same-work set, the fault and fairness tests, the batch test, and the six organisms at every size; the Azure burst bill test and the two big organisms on rented Azure machines too. The card harness changed only in how it judges (amendment 11 of the GPU preregistration), so the single card and the eight cards run once, on this engine, on Lambda.

Back on the frozen engine so far, ten pairs each:

- **Faults** (`results/live/FAULTS.md`): p95 −60%, mean response −35%, time over the line −23%, pending pods −77%. Recovery is faster after every fault: machine down 42 s against 70 s, a blind probe 54 s against 66 s, a runaway pod 98 s against 105 s, a spike the same.
- **Fairness** (`results/live/FAIRNESS.md`): a noisy neighbour on the same cluster. Mean response −15%, no LOSS, and the neighbour's own app never behind. The earlier engine scored −0.3% on the index here; this engine scores +5.6%.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Independent simulator: CityLearn round 1 split (the 2022 battery districts lower on bill -4% to -11%, electricity -9% to -17%, carbon -7% to -14%; the 2020-2021 water-tank districts higher on peaks and ramping), the fix (only the electric batteries are steered), and round 2 on every untouched district (`docs/CITYLEARN_PREREGISTRATION.md`).

89.8.2 Measured on real systems: the newest set, Omni-Compass against Kubernetes as it runs today

Set 24 (2026-10-02, commit `c908054`) repeats it again: machines in service −31.6%, p95 −60.1%, p99 −64.1%, HPA replicas −38.6%, 0 failed requests, total CPU including Omni-Compass's own −1.8% (not significant) (`results/live/LIVE_REPS_24.md`). Set 23 before it: p95 −62%, replicas −37%, pod starts −64%, 0 failed requests, no energy or total-CPU difference (`results/live/LIVE_REPS_23.md`). The set-22 table below stands as first measured.

Set 22 (`results/live/LIVE_REPS_22.md`): 10 paired repetitions on real Kubernetes (kind), each pair on one machine, Kubernetes with its autoscaler alone against the same Kubernetes with Omni-Compass on top. The load is sent at a fixed rate, so both arms were given **the same work**.

Result	Kubernetes alone	With Omni-Compass	Change (95% interval)
Energy, parked machines still on at idle power (declared model, no meter)	160.3 Wh	160.1 Wh	**−0.1%, no difference**
Response time, 95th percentile	407.9 ms	158.8 ms	**−61%** (proven)
Response time, 99th percentile	639.4 ms	245.1 ms	−62% (proven)
Response time, mean	179.9 ms	98.4 ms	−45% (proven)
Failed requests	0	0	equal
Pods waiting to start, pod-minutes	0.265	0.025	−91% (proven)
Replicas, mean	8.93	6.91	−23% (proven)
Machines in service, mean (all stayed powered)	6	4.14	−31% (proven)
CPU used by the service	1.036 cores	0.957 cores	−7.6% (proven)
Omni's own CPU (its controller and every command it ran)	0	0.070 cores	+0.070 (proven)
CPU used, service and Omni together	1.036 cores	1.026 cores	**−0.9%, no difference**

- **Same work, much faster answers**, with no failed requests and far less waiting.
- **No energy saving is shown on kind.** Every machine stays powered; energy is a declared model, and counted at the idle power a parked machine really draws it is unchanged.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **No CPU saving once Omni's own cost is counted.** The service used 7.6% less CPU; the controller spent almost all of it. Cutting the controller's cost is the next improvement.
- The reset restored every setting in every run.

89.8.3 Kubernetes sets 25 and 26 (2026-10-02, 10 paired repetitions each, equal work)

Run	Machines in service	p95	Failed	Total CPU incl. Omni's own	Receipt
Set 25, the engine's allocation law	**−32.3%**	**−57.3%**	0 / 0	−0.6% (not significant)	`results/live/LIVE_REPS_25.md`
Set 26, the engine's allocation law	**−35.8%**	**−55.4%**	0 / 0	−1.5% (not significant)	`results/live/LIVE_REPS_26.md`
Set 26, **the compass law in the live controller**	**−17.2%**	**−64.8%**	0 / 0	+1.0% (not significant)	same; label by the preregistered rule: **fewer machines within the band**
Set 27, the engine's allocation law	**−36.6%**	**−53.1%**	0 / 0	−0.0% (not significant)	`results/live/LIVE_REPS_27.md`
Set 27, **the compass law aligned with the GPU governor**	**−15.9%**	**−65.5%**	0 / 0	+0.2% (not significant)	same; label by the preregistered rule: **fewer machines within the band**

Set 27 (running): the compass in the live controller reads the service as the corrected GPU compass does (mean response time, center 0.4), against native and the allocation law (`docs/K8S_COMPASS_PREREGISTRATION.md`).

89.8.4 Measured on a real GPU: the card's own meter (evidence class P)

First counted run, NVIDIA A10 on Lambda, 2026-10-02 (`results/gpu/run-20261002T082232Z/GPU_REPS.md`, 10 paired repetitions × native / watch / Omni, 600 s each, frozen at commit `c908054`, checksums verified). Wire check 7 of 7; 2,144 writes, none refused, every one read back, every arm ended at the start limit; watch equal to native.

Gauge	Native	Omni	Change (95% interval)
Work per energy (requests per kJ)	50.79	52.62	**+3.6% (+2.7% to +4.5%), proven**
GPU energy	69,180 J	66,790 J	−3.5%, proven
Requests served / not served	3,514 / 0	3,514 / 0	equal
Response time, 95th percentile	510 ms	809 ms	**+58.5%, higher, proven**

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Result, by rule: ENERGY IMPROVEMENT WITH SERVICE TRADEOFF (the p95 guardrail of +10% failed). The six organisms with the same card inside (`results/hil/run-20261002T082232Z/HIL.md`, 3 repetitions each): the card's work per energy +1.6% to +2.8% in every organism, the same requests, its p95 500 to about 600-935 ms. The cause, from the card's own samples, was wiring in the governor (amendment 6 of `docs/GPU_PREREGISTRATION.md`): busy bursts served at 736-768 MHz against 861-889 MHz on its own. Corrected (amendments 6 and 7); the corrected governor has not yet run on a card.

89.8.5 Simulated (models: they show the mechanism, not a measurement)

Result	Where
GPU governor with share floor and busy gate (one wire, the power limit), MLPerf-calibrated card: +5.1% and +1.3% work per kJ, p95 within +10%	`results/gpu/sim/after`
Two-wire GPU card under the compass law, corrected governor (amendments 6-7), 10 seeds and 10 fresh seeds, geometric means: **service** profile work per energy **+6.9% / +3.8%**, energy −6.4% / −3.7%, p95 **−5.9% / −2.3%** (faster), time over the line −0.03 / −0.04 pp; **batch** profile +8.1% / +4.2%, p95 +7.0% / −2.3%; the one-wire governor +0.1%; both wires restored every seed	`results/sim/gpu_two_wire/RESULT.md`, `fresh/`
The six organisms (Compute 345, Physics 262, Energy 282, Distribution 337, the four stacked 1,226, the whole tower 656), native against the compass law on every muscle, 1,000 paired runs at 1× and at 10× size: work per energy +0.20% to +0.30%, energy −0.21% to −0.32%, work −0.01% to −0.02%, time over the service line **+0.19 to +0.27 pp in every cell (band first not held)**, every knob handed back. 100× and 1,000× are running	`results/scale/GRID.md`
Speed lock (speed won elsewhere spent on GPU watts)	`results/gpu/sim/pipeline/`
CPU and GPU on one conserved power budget: +1.4% to +5.7% work served against a fixed cap, never over the budget	`results/hardware/NODE_EXCHANGE_*.json`, `docs/CONVEYANCE_LAW.md`
GPU groups sharing a site budget: 0 minutes over the budget	`results/hardware/SITE_EXCHANGE_HELDOUT_*.json`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Result	Where
Platform leagues, faults, PlanetLab traces, stack benchmark	`tuning/`, `results/protocol/`, `results/` (see `docs/history/BENCHMARK_REPORT.md`)
The 656-muscle tower as organisms, round 3 (preregistered, 10 seeds; every realm carries the shared spine; Omni as the shipped controller commands): the whole tower native against one governor on top, work per energy **+0.1%, SUPERIOR WITHIN GUARDRAILS**; inside the realms the spine costs service: Energy +0.2% with +1.9 pp violations (tradeoff), Compute 0.0% (+2.1 pp, not established), Distribution −0.1% and Physics −0.7% (**AWAY FROM ITS AIM**). Rounds 1 and 2 kept, superseded	`results/realms/REALMS.md`, `docs/REALM_MUSCLES.md`

Back Matter

BACK MATTER

Glossary

Term	Meaning
Antagonist pair	the up side and the down side of a muscle's control, each with its own gain
Authority	how far the nervous system lets an organ move this decision
Band	a reading's or a knob's safe range
Compass	the band seen as a position from 0 (calm) to 1 (the line), with its bottom in the middle
Term	**Meaning**
STEADY	Equalized, Verified baseline, Equilibrium, Neutral: the mean change under 0.5% (under the floor), or

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

Term	Meaning
	nothing moved (the same), or a knob at its limit on native; the key, front matter
GAIN	Growth, Advantage, Improvement, Net-positive: a gauge moved the way its declared aim asks, against native; a resource cut is a GAIN; the key, front matter
GAIN in all three of our runs	the mean change 0.5% or more, every run (A, B, C) moved the same way with its 95% interval clear of zero, and that way a GAIN for the gauge's aim
GAIN by the mean of our three runs	the mean change 0.5% or more toward the gauge's aim, not every run clear of zero; the count of runs beyond the noise stands beside it (Chapter 59)
LOSS	Leakage, Off-track, Setback, Subpar: a gauge moved against its declared aim (less work, a longer wait, more misses); it should never appear, and where it does it is shown, its cause found and fixed; the key, front matter
Power given	a resource spent or held that rose: what Omni put in to buy the work and speed beside it; shown, never called a loss
Cover	a knob's hard range; every write is clipped to it
Cushion	the 5% at each edge of the compass, 10% in all
DEX-YLL-1	the company's number, 1-888-DEX-YLL-1, read in order as the engine runs: DEX, Data Exchange (the input, the two-way plug); YLL, Yield Limit Line (the boundary: every muscle up to its own yield limit, never past it); 1, one closed loop (the output; in code 1 is true, in science 1 is unity)
Fail up	the return to full capacity the moment service crosses the wall or a sense goes blind
Governor	the process that reads, decides and writes; Omni-Compass
Muscle	any machine, service or controller Omni-Compass reads and sets

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Term	Meaning
Native	the system as it runs without Omni-Compass: every muscle under its own native controller, as its vendor ships it (the native baseline)
Omni-Compass on native	the second arm: the native system with Omni-Compass on top of it ("omni")
Omni-Compass direct	the third arm, Omni-Compass by itself: each knob's native controller switched off and Omni-Compass the only controller moving it (section 1.1)
Factory profile	the complete, versioned set of Omni-Compass default settings shipped together (section 76.8; `docs/FACTORY_PROFILE.md`)
Candidate, active and custom profile	a proposed combination under evaluation; the settings actually governing the current run; an identifiable configuration that differs from the released factory profile (section 76.8)
The best validated factory profile for the declared operating conditions	the profile the eight steps of section 76.8 establish; the meaning "optimal" has here, and the only one
Restore factory profile; Return to native	the two restoring controls: reapply the released configuration; hand governance back and restore the recorded native settings (the reset)
The ten organisms; the twenty scenarios	the seven of the catalog, the orchestra, the live benchmark engine's organism and the whole organism, each read native and on native (sections 34.7 and 60.10)
The cloud is a wire	a cloud is the wire between the software end and the bare metal; Omni-Compass can be wired in at all three and acts in each from the software end (section 60.6)
Beyond the noise	a run whose 95% interval excludes zero; a three-run reading carries the count of its runs beyond the noise (Chapter 59)
Off the clock	a repetition in which either arm ended more than 5% of its window late; marked, the pairing stands
Organism	a set of muscles run together on one clock

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Term	Meaning
Omni index	the one combined number: the geometric mean of every real category's work, speed, machines and energy ratios, each read by the three-run rule
Omni v1, v2, v3	the frozen engines, fingerprinted file by file; a result belongs to the engine its commit carries
Plug	the two-way connection to one muscle: read, write, read back, restore
Pool (Azure)	one machine family under Azure's autoscaler with its own ceiling; several pools make the fleet
Profile (service or batch)	a named set of the compass's settings for one kind of work, service (the default) or batch: a setting inside a configuration profile
Race	full speed at once while work waits, so a burst is never served slowly
Yield limit line	a muscle's own limit, read live: Omni-Compass takes it right up to the line and never past it, as an engineer loads a material up to its yield limit, the most it carries and still springs back unharmed
Speed floor	the clock a card reaches on its own while busy, learned from its own meter; the governor never sets the ceiling under it
Receipt	the paired record of native against Omni-Compass for one run
Snapshot	a knob's value read once before the first write; the restore point
The runs disagree	runs clear of the noise point different ways; the test is unstable on that measure and is looked into
Wire check	the test that proves every wire follows, reads back and returns before anything runs
Work per energy	work done divided by energy used; the primary outcome
Work inside the line	the requests, transactions or messages a second answered within the response line; the product number on every real stack

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Term	Meaning
One pedal	push for more, lift off for less, idle (the pedal lifted all the way), reset (everything back to native): how the governor moves capacity under autopilot
Cruise	every machine in service while work waits for a place, held without second-guessing until the line has been empty for two decisions
Idle at once	the work done and demand at zero: the pedal lifted all the way in one move, every safety check still holding
Kill switch	security only: one switch in a human hand that turns every governor on the machine off at once; never the reset
Lease	the record every governor renews each decision; a lease older than its limit, or a dead process, makes the watchdog hand back for it
Watchdog	the service beside Omni-Compass's processes that hands back for any of them that died or hung without doing it itself
Verdict	the paired trial on the muscle itself that allows a slow knob to move only where the cost is within 2%; "left native" where no step passes
Slack gate	v3's rule: a motion axis busy more than half the time at full speed keeps its speed native
Tuning case	the one workload, cell or swarm the rules were fitted on; shown in every table and never counted
Untouched case	a workload, cell or swarm the rules were applied to unchanged; the judged rows
Knee	nine tenths of a system's measured capacity, where its queue begins to grow; the broker's native was set there by design
Amendment	a change to a preregistration after it was written, with its time and reason; one made after a result was seen says so

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Term	Meaning
Dwell	the seconds after a knob moves during which the law will not move it back
Notch	the smallest step a knob moves in one decision (one consumer, 8 MB of cache, one tap)
Evidence class P, L, S	a physical meter; live software with no meter; a model of ours
Handed back	the knob read back at the operator's value at the end of an arm; every table says whether every arm was
Off the clock	see above; a repetition whose arm ended more than 5% of its window late
Own cost	the governor's CPU (its process and every command it ran) as a share of one core over the window, from its audit; a few thousandths of a core at every size
Smoke run	one repetition that exercises a harness end to end before any counted run; never counted, always recorded
L + S	an organism run with a real cluster inside: the cluster is L, the organism around it S
Working set	the records a workload actually touches over a window; a cache benchmark measures nothing unless the working set reaches the cache
Key space	the records a benchmark may ask for at one notch; in the MongoDB test the knob's load, stepped one notch at a time
Uniform draw	every record in the key space equally likely, so the working set is the key space; YCSB's shipped zipfian draw concentrates on a few thousand hot records whatever the key space
Ordered keys	records named in load order, so a run that asks for record n finds record n; a run with hashed keys against an ordered load asks for records that do not exist

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Term	Meaning
Full-cache gate	the MongoDB and Redis rule: slow reads grow the cache only while the cache is full (nine tenths used), because a miss in a cache with room to spare is not the cache's to mend
Buffer pool	InnoDB's cache of table and index pages, the one memory setting every MySQL operator sizes; resized online by the server in whole chunks
Chunk	the unit in which MySQL resizes its buffer pool (128 MB as shipped); the knob's notch on that stack
Page cache	the operating system's own cache of file contents; where the data fits in it, a storage-engine miss is a read from memory and a decompression, not a disk read, and the gain available to the cache knob is smaller
Data path	the route the work's own data takes (requests, packets, files, bytes); Omni-Compass is never in it: it reads the gauges (one wire in) and writes the settings native controllers already accept (one wire out)
The seat	where Omni-Compass sits: in one place, the software end, on top of every controller the stack runs, as one body; it changes nothing in the silicon or the cloud's back end, and its effect is carried along the whole path the work travels
The three layers	the chip, the cloud and the software, where the industry attacks the cost of computing; each layer's own answer moves its own terms of the one equation, and Omni-Compass's gain is read on top of it (`docs/INDUSTRY_LANDSCAPE.md`)
Work for the bill, E	the work done over the bill, E = W / B; the gain G = E(Omni-Compass on native) / E(native) − 1 = (1 + ΔW) / (1 + ΔB) − 1 (`results/TWO_BILLS.md`)
Four arms	A and B, native and Omni-Compass on native on bare metal; C and D, the same through the cloud; each read by its bill, the work done inside it and the work per dollar

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Term	Meaning
Alert minutes	whole minutes whose 95th percentile, failed requests counted over, was over the response line: the minutes an on-call page would be open, native beside Omni-Compass; the oversight the record measures, never people

APPENDIX

Appendix A. Command Reference

Task	Command			
Verify everything	`python3 verify.py`			
Seven organisms, modelled	`python3 tools/run_scale.py --runs N --scale K --out <dir>`			
The full ladder	`bash scripts/scale_ladder.sh`			
Two-wire card, modelled	`python3 tools/run_gpu_card.py <dir> [fresh]`			
GPU wire check	`sudo python3 tools/gpu_wire_check.py --gpu 0`			
GPU, whole benchmark in one command	`sudo nohup bash scripts/gpu_rented_run.sh > run.log 2>&1 &`			
The seven organisms with the real card inside	`python3 tools/run_hil.py --out <dir>`			
GPU governor, two wires	`sudo python3 -m omni_controller.gpu_compass --mode watch	cap ...`			

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Task	Command			
Kubernetes, watch	`kubectl apply -f deploy/install/omni-compass.yaml`			
Kubernetes paired runs	`scripts/kind_paired.sh`, then `tools/live_reps.py`			
OFF (Kubernetes)	`touch /tmp/omni.kill`			
OFF (GPU)	`sudo touch /tmp/omni-gpu-kill`			
The whole harness OFF, ON, status, watchdog	`python3 tools/omni_switch.py off	on	status	watchdog`			
Seal check	`python3 tools/seal.py --check`			
Which engine a checkout or a commit carries	`python3 tools/omni_version.py [--commit <sha>]`			
The three-run table (Kubernetes, Azure)	`python3 tools/confirm_abc.py "<title>" raw/run-<A> raw/run-<B> raw/run-<C> --out results/live/V3_<TEST>.md`			
The three-run table (database, messaging, cache, swarms, robots, grid, buildings)	`tools/pgbench_abc.py`, `tools/kafka_abc.py`, `tools/redis_abc.py`, `tools/swarm_abc.py`, `tools/mujoco_abc.py`, `tools/pandapower_abc.py`, `tools/citylearn_abc.py`, the same arguments			
The organisms with the cluster inside	`python3 tools/six_kube_report.py <raw dirs> --out results/live/V3_SIX_KUBE.md`			

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Task	Command			
The grid of copies and runs	`python3 tools/grid.py` (reads `results/scale/receipts/`)			
The Omni index	`python3 tools/omni_index.py`			
Which knobs earn a wire in (write, watch, operator's choice)	`python3 tools/wiring_verdicts.py` (`--check` compares the page with the tables; `verify.py` runs it)			
One number per benchmark, plus always toward the system's own aims	`python3 tools/benefit_sheet.py` (`--check` the same way; `verify.py` runs it)			
The database benchmark, one run	`python3 tools/run_pgbench.py --out <dir>` (workflow `pgbench`)			
The message broker, one run	`python3 tools/run_kafka.py --setup`, then `--workloads light,heavy,burst --out <dir>` (workflow `kafka`)			
The cache, one run	`python3 tools/run_redis.py --setup`, then `--workloads small,large,burst --out <dir>` (workflow `redis`)			
The database's storage-engine cache under YCSB, one run	`python3 tools/run_ycsb.py --setup`, then `--workloads b,c,f,burst --out <dir>` (workflow `ycsb`)			
The database's buffer pool under sysbench, one run	`python3 tools/run_sysbench.py --setup`, then `--workloads read_only,read_write,up`			

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Task	Command			
	`date_index,burst --out <dir>` (workflow `sysbench`)			
The robustness test	workflow `robustness`: `scenario` kill or long, `reps`, `duration_s`; the own-cost table `python3 tools/own_cost.py <raw run dirs> --out results/live/V3_OWN_COST.md`			
The drone swarms, one cell	`python3 tools/run_swarm.py --cell short	mixed	long	all --out <dir> (workflow swarm`)
The independent simulators	`python3 tools/run_citylearn.py`, `run_pandapower.py`, `run_mujoco.py` (workflows `citylearn`, `pandapower`, `mujoco`)			
Azure, the bill	workflow `aks-metered`: `reps`, `arms`, `duration_s`, `load_steps`, `worker_pools`, `pool_prices`, `hpa_max`			
The big organisms, detached	workflow `big-organism-detached`: `mode` start / collect / survey, `test` organism / scale / robust / direct, `organisms`, `size`, `duration_s`, `commit`, `max_hours`			
Omni direct on a rented cloud machine	`test` = `direct` on `big-organism-detached` (Azure) or `cloud-organism` (`cloud` gcp or aws): the three arms' full form, `reps` runs; `dry_run` yes shows the price and rents nothing			

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Task	Command			
Archive a finished run with the code	nothing to do: workflow `archive-run` takes it within the hour; to take it at once, add its id to `.github/archive_request.txt` and push			
Verify before a push, as GitHub runs it	`python3 tools/release_manifest.py` under Python 3.12: 0 FAIL			

APPENDIX

Appendix B. File Map

Path	Contents
`omnicompass/`	the engine, governor, nervous system, shield, compass, conveyance law, the compass
`omni_controller/`	the Kubernetes controller and muscles; the GPU governors (one and two wires)
`realms/`	the 1,107-muscle catalog of v5 (`catalog_v5.csv`; v3's 945 in `catalog.csv`, frozen), every muscle's own card (`muscle_cards_v5.csv`), the plant models, the realm harness, the compass on every muscle (the max, `compass_arm_v5.py`), the modelled card
`tools/`	benchmarks, receipts, the wire check, the scale ladder, the card search (`tune_cards.py`), manifests, seals
`scripts/`	one-command runs (GPU, Kubernetes, ladder)
`deploy/`	container image, install and permission files
`cpp/`	the C++20 twins
`results/`	every published result, with its raw files and checksums

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Path	Contents
`results/live/V1_*.md`, `V3_*.md` (+ `.json`)	the three-run tables, one per test, named by the engine they ran on
`results/live/raw/run-<id>/`	every archived run's files, one SHA-256 manifest per repetition (the branch `raw`, opened by `scripts/raw_archive.sh`)
`results/grid_v5/GRID.md`, `results/realms_v5/REALMS_V5.md`, `results/OMNI_INDEX.md`	the grid of copies and runs, the modelled muscles and organisms, the one combined number (the older engines' tables stay under their own names)
`OMNI_V11.json` (the engine that stands), `OMNI_V10.json`, `OMNI_V9.json`, `OMNI_V8.json`, `OMNI_V7.json`, `OMNI_V6.json`, `OMNI_V5.json`, `OMNI_V3.json`, `OMNI_V2.json`, `OMNI_V1.json`	the engines' fingerprints
`docs/`	this manual, the preregistrations, the evidence ledger, the theorem, the realm study
`docs/OMNI_V7.md`, `OMNI_V6.md`, `OMNI_V5.md`, `OMNI_V3.md`, `OMNI_V2.md`, `OMNI_V1.md`	what each engine is and every result read on it
`docs/REGISTER.md`, `docs/PROOF_PROGRAM.md`	every muscle, every benchmark run and every benchmark still to run; the program to full size
`.github/workflows/`	every benchmark as GitHub runs it: `benchmark-reps`, `six`, `six-kube`, `big-organism`, `big-organism-detached`, `aks-metered`, `pgbench`, `kafka`, `redis`, `ycsb`, `sysbench`, `robustness`, `swarm`, `citylearn`, `pandapower`, `mujoco`, `archive-run`, `verify`
`tests/`, `verify.py`	every unit and property test, the shield's adversarial cases, the Python-against-C++ agreement; `verify.py` runs them all and must end with its pass line
`tools/omni_version.py`, `tools/release_manifest.py`, `tools/layout_check.py`	which engine a checkout or commit carries; the release manifest and verification as GitHub runs it; the check that every path the documents name exists

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Path	Contents
`tools/confirm_abc.py` and its siblings (`pgbench_abc.py`, `kafka_abc.py`, `redis_abc.py`, `ycsb_abc.py`, `sysbench_abc.py`, `swarm_abc.py`, `mujoco_abc.py`, `pandapower_abc.py`, `citylearn_abc.py`)	the three-run tables, one tool per kind of raw record, each checking the engine of every run it reads
`tools/omni_index.py`, `tools/dossier.py`, `tools/own_cost.py`	the one number from the tables; the dossier from the tables; the governor's own cost from the archived audits
`tools/wiring_verdicts.py`, `docs/WIRING_VERDICTS.md`, `results/WIRING_VERDICTS.csv`	the verdict per knob from every table: write, watch or the operator's choice, every loss with its cause; one row per knob and per muscle
`tools/knob_verdict.py`	the brain's own verdict on a live knob, around the engine's `omnicompass/verdict.py`: watch first, one notch a trial, the allowance, the two objectives; used by the five live harnesses
`tools/benefit_sheet.py`, `docs/BENEFIT_SHEET.md`, `results/BENEFIT_SHEET.json`	one number per benchmark from the tables, plus always toward the system's own aims, with yes, no, none or trade beside it
`tools/legal.py`	the legal notice every generated report carries at its head and foot
`docs/book/`	the builder of this manual's PDF (`build_book.py`) and the theory chapters bound into it
`release/`	the copyright deposit and the release notes, printed at named commits
`CHANGELOG.md`, `docs/STATE_OF_PLAY.md`	what changed, by date; where everything stands today
`docs/*_PREREGISTRATION.md`	the rules of every benchmark, written before it ran, with every amendment and its time
Path	**Contents**
`docs/DOSSIER.md`, `docs/dossier/`	every result in one place, with its charts, built by `tools/dossier.py` from the tables

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Path	Contents
`docs/HISTORY.md`, `docs/history/`	earlier states of play, earlier engines' sets and the pre-v1 index, kept whole
`LICENSE`, `NOTICE`, `LICENSES/`	the license and notices

APPENDIX

Appendix C. The Equations in Full

```
(1) dE/dt     = −α[E] E + β[int] + β[ext] + v[eff]
(2) dU/dt     = μ U (1 − U²) − (dE/dt)/E[max] − λ[U] U + u,
                |u| ≤ U_AUTHORITY = 25
(3) dI[U]/dt  = (1 − U) − σ₁ E − δ S − λ[I] I[U]
(4) v[eff]    = cos(ω[B] t / 2) · c · tanh(λ₀ + λ₁ (U − 0.5) + λ₂ S)
(5) Φ(S)      = αₛ S² / 2 + βₛ S³ / 4 − δ S

(6) dS/dt     = −dΦ/dS = δ − αₛ S − (3/4) βₛ S²
(7) dB/dt     = Ḃ ;  dḂ/dt = γ[c] δ S − (ω[B] / Q[B]) Ḃ − ω[B]² B
(8) R[B]      = finite-difference audit of (7) at every step;
                never fed back into the state

Control (one micro step, zero-order hold across all four RK4 stages):

    u = clip(−f[U](x, t) + K[P] (σ − U), −U_AUTHORITY, +U_AUTHORITY)
    K[P] = 12,  σ ∈ {−1, +1}

The compass (every muscle):
    p = position of the service reading in its band
        (0 calm, 1 the line)

    F = A tanh((K[P] (p − center) + K[D] v) / A)
    K[D] ≥ critical damping
    p ≥ 0.95  ⇒  full up force; down side held
    knob ← clip(knob + g[side] F span, cover)

The GPU governor (two wires, omni_controller/gpu_compass.py;
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
one law, amendments 8 to 10):
    p = (mean response of the last 5 s − S) / (SLO − S),  S = SLO / 10
    p95 ≥ SLO, a failure, blind  ⇒  fail up
    fail up / race (utilization ≥ 0.95)
        ⇒  ceiling = top clock, lid = start limit
           (the card's own settings)

    steady under the limit (saturated, drawing ≥ 0.97 of the limit)
        ⇒  ceiling = the card's own busy clock, lid = start limit
           (the same watts, no knock-backs)
    otherwise:
        step = round(g[side] F f[top] / 15 MHz) · 15 MHz
        ceiling ← clip(ceiling + step, c[floor], f[top])

        c[floor] = max(f[busy,own] × floor, f[top] − k* 15 MHz)
                    (never under the card's own busy clock, never past
                     the verdict's deepest step k*)
        lid = clip(ceil(1.10 P[busy,own]), envelope floor,
                    start limit)
    g[up] 0.10, g[down] 0.0125, center 0.4, floor 1.00

The verdict (omnicompass/verdict.py; every slow knob, the GPU ceiling
and the Kubernetes machine count):
    reference r = the costs of n requests at the deepest allowed step
                  (a card: at native), measured fresh
                  (Kubernetes n = 200; a card n = 30)

    trial t     = the costs of n more at one step past it, under the
                  same traffic
    d = mean ln c[t] − mean ln c[r] ± 1.96 √(s²[r]/n[r] + s²[t]/n[t])
                  (Welch); stepwise a second interval against the
                  costs first measured at native; τ = ln(1 + a), a = 0
    ↪ .02

    LOSS   iff an interval lies wholly above 0  ⇒  refused
    wide   iff a half-width > τ and n[t] < 3n   ⇒  measure on
    allow  iff median t ≤ min(r, c[native]) (1 + a)  and  d ≤ τ
           (else refused, past the allowance)
    a trial begins only while calm, P after the last began
    (Kubernetes 600 s; a card 8 decisions); a phase past its limit
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    (Kubernetes 1,200 s; a card 30) or out of calm is abandoned
    a refused step is not tried again for R (Kubernetes
    R = 7,200 s; a card 900 decisions = 30 min); the knob never goes p
    ↪ ast
    the deepest allowed step, so steps cannot add up beyond the
    allowance; on the max the machine count gives nothing back

Kubernetes, the compass on the HPA target
(omni_controller/controller.py; sets 30 and 31):
    target x ∈ [0.6 x[op], x[op]] (times the conveyed gain);
    the up force lowers x (more pods)
    p ≥ 0.95 from load (line breached, every sense live, nothing

    pending)  ⇒  x = 0.6 x[op] at once
    p ≥ 0.95 from a blind sense or pods waiting for a lost machine
        ⇒  x = x[op] (native's own)
    fault over (p < center, line clean, nothing pending)
        ⇒  x = x[op] at once, never held
    machines: one more at once past the wall; one back only when the

    verdict and the release gate agree
    g[up] 0.10, g[down] 0.02, release force < −0.2

The productivity arithmetic (every receipt; manual section 76.4):
    work W equal in both arms;  G = C[native] / C[omni] − 1;
    the same work needs 1/(1 + G) of the resources;

    saving S = G / (1 + G):  G = 1/3  ⇔  S = 1/4
```

The symbols, and their names in the code. The equations are written in the symbols above; the source (`omnicompass/core.py`, `omnicompass/adapter.py`, printed in Appendix H) spells each one out, and an engineer reading the two side by side needs the correspondence once. The values are those the live controllers run (`STACK_PARAMS` in `omnicompass/adapter.py`); the pressures and the drive are computed from the nine observations every decision and have no fixed value.

Symbol	In the code	What it is	Value in the live controllers
α[E]	`alpha_E`	the deviation's drain rate	3.487
β[int], β[ext]	`beta_int`, `beta_ext`	the internal and the external pressure on the deviation	computed each decision
v[eff], c	`v_eff`, `c`	the bounded drive and its bound	c = 1.0

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Symbol	In the code	What it is	Value in the live controllers
λ_0, λ_1, λ_2	`lambda_0`, `lambda_1`, `lambda_2`	the drive's offset and its weights on the alignment and the stress	−0.40, 1.55, 1.15
μ	`mu`	the depth of the alignment's double well	3.782
E[max]	`E_max`	the deviation scale in the alignment's equation	2.0
λ[U]	`lambda_U`	the alignment's own damping	0.0
σ_1	`sigma_1`	the deviation's weight in the memory	0.38
δ	`delta`	the stress's drive (the engine's own default is 0.5)	0.705
λ[I]	`lambda_I`	the memory's leak	0.719
α_s, β_s	`alpha_s`, `beta_s`	the coefficients of the cubic potential Φ(S)	0.12, 0.10
γ[c]	`gamma_c`	the stress's drive on the bath	1.0
ω[B], Q[B]	`omega_B`, `Q_B`	the bath's natural frequency and quality	1.0, 2.5
$\dot{B}$	`B_dot`	the bath's rate, the engine's only second-order element	state
R[B]	`R_B`	the finite-difference audit of the bath, never fed back	recorded
K[P]	`KP`	the control law's gain	12
u, U_AUTHORITY	`u`, `U_AUTHORITY`	the command and its authority	±25
σ	the target pole	+1 (healthy) or −1 (failed), the nearer basin by default	±1
f[U]	computed inside `control_command`	the drift of U with the command at zero	computed each micro step

Parameter ranges, defaults and the proof of convergence: `omnicompass/core.py`, `docs/TRACKING_THEOREM.md`, `docs/CANONICAL_ENGINE.md`.

APPENDIX

Appendix D. Metrics

Every gauge, where it comes from, and whether it is measured or modelled: `docs/METRICS_CATALOG.md`. The gauges that appear in the three-run tables of this manual, with their source and their direction, are these:

Gauge	Source	Measured or modelled	Direction
work inside the response line (requests, transactions or messages a second answered within the line)	the probe's own records, pgbench's log, the consumers' records, the application's records	measured	the aim is higher; the product number
response time, mean, median, 95th and 99th percentile	the same	measured	the aim is lower
time over the response line (share of samples)	the same, against the preregistered line	measured	the aim is lower
failed requests, lost messages	the same	measured	any increase is marked
alert minutes: whole minutes whose 95th percentile, failed requests counted over, was over the line	the probe's own records, minute by minute	measured	the aim is lower: the minutes an on-call page would be open
settings commands Omni-Compass wrote on its own	its own audit	measured	shown, not judged (no person touched either arm)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Gauge	Source	Measured or modelled	Direction
the governor's additions decided while the service was still inside its line (% of its additions)	the governor's audit	measured	shown, not judged
worker machines in service, mean; node-hours	the cluster's own node records every 15 s	measured (machine-hours on kind; Azure's own count on AKS)	the aim is lower
compute bill at list price	Azure's own machine count × list price per family	measured (a real bill)	the aim is lower
energy (Wh), the standby model	a declared formula over the machines in service (kind)	**modelled**, said so on every line	the aim is lower
host CPU busy; host CPU-seconds; CPU-seconds per 1,000 units inside the line	`/proc/stat` of the real machine under the test	measured	the aim is lower
Omni's own CPU (cores), mean	the governor's audit (its process and every command it ran)	measured	shown, not judged in the Kubernetes tables; a loss in all three of our runs where it is one
connections held open, consumers running, memory ceiling held	the pooler's, the group's, the cache's own reports	measured	the aim is lower (the resource held)
cache hit rate; consumer lag	Redis's INFO; the consumers' records	measured	the aim is higher; the aim is lower
HPA replicas, pods started, pod start wait	the API server's own records	measured	shown, not judged except pod start wait
organism work, energy, time over its line	the organism's plant models	**modelled**	by direction; S class
energy a mission, missions a charge (drones)	the simulator's motor constants through a declared model	**modelled**	lower; higher

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Gauge	Source	Measured or modelled	Direction
cache size held, mean; bytes in the cache, mean; pages read into the cache (MongoDB)	the server's own `serverStatus` (WiredTiger cache)	measured	the aim is lower (the resource held); shown, not judged (pages read)
seconds from the kill to every setting back at the operator's (robustness)	the harness polling the cluster once a second from the kill	measured	the aim is lower; past 60 s marked; never, INVALID
the governor's resident memory, last ten minutes over the first ten (robustness, long run)	the process table, sampled every 15 s by the harness	measured	a growth over a quarter is marked
decisions made of expected; failed decisions (robustness, long run)	the governor's audit	measured	under 95% INVALID; any failed decision shown with its reason
mission time, position error, collisions (drones)	the simulator's own state at every step	measured in the simulator (S class)	lower; under the safe error; any collision voids the cell
handed back (every arm)	the knob read back at the end of the arm	measured	yes in every arm, or the run is invalid
off the clock	the organism's own clock against its window	measured	shown; marks the cell

Three rules for reading any gauge in this appendix. A measured gauge is one the system under test, or the host's own kernel, reported about itself; a modelled gauge is one computed from a declared formula over measured inputs, and every table says which it is on the line itself, never only here. A resource gauge (machines, connections, consumers, memory, cache) is always judged as aiming lower, even where the governor's purpose was to add the resource to buy service, so that a gain bought with a resource is paid for in the same table and in the index. And a gauge marked "shown, not judged" never enters a reading or the index; it is there so that a reader can see what the governor did (how often it moved, how many pages it read, how many pods it started), not to be counted for or against it.

All patents, copyrights and trademarks filed in the USA.

APPENDIX

Appendix E. Troubleshooting

Symptom	Cause	Fix
Wire check `FAIL 3 up wire (lock)`	the driver or VM refuses clock locking	use bare metal or full passthrough; or run the one-wire governor
Wire check `FAIL 3 up wire (follows down)`	the card ignores the ceiling	update the driver; check for another management agent holding clocks
Wire check `FAIL 4 down wire`	the power limit is refused or capped by the board	check `nvidia-smi -q -d POWER`; run as root
`another copy of this test is already running`	a second copy was started	wait for the first or reboot; start once
`something else is using the GPU`	another process holds the card	stop it; the benchmark must run alone
Governor exit 5	another writer changed a knob	find the other controller; Omni-Compass left its value alone
Governor exit 3	a restore did not read back	restore by hand (`nvidia-smi -rgc`, `-pl <start>`); investigate before rerunning
`decision failed (n in a row)`	the cluster API is unreachable	turn it OFF; native runs on
Energy saved but p95 slower than native	the card served bursts below its own clock, or the lid sat under its own draw	read section 42.5; in the audit compare `telemetry.clock_mhz` while busy with `native_busy_clock_mhz`, and `want_w` with `native_busy_draw_w`

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Symptom	Cause	Fix
Fail-up in most decisions	`--slo-ms` set too low for the workload, or a stale feed read as blind	set `--slo-ms` from the workload's own target; check the feed's age
No saving at all, service unchanged	the card is saturated almost all the time (it races), or the service sits above the compass's center	expected on a card with no slack; the saving comes from the quiet stretches
Kubernetes: no machine ever given back	the release gate refuses (its reason is in the audit), or the service is above the compass's center	read `node_gate.reason` in the audit; check `--slo-ms` and the latency feed
Kubernetes: a repetition marked OFF THE CLOCK	the machine could not step the organism inside its window	a longer window for that size on that machine; never a faster reading of the same run
Broker: consumers climb to the cover and stay	messages wait at every step (the producer is past the group's capacity)	the benchmark's capacity step sets the peak at nine tenths of the operator's group; check the measured capacity in the run's log
Cache: the ceiling grows while little memory is used	cold misses read as pressure	the full-cache gate is the rule (used ≥ 90% of the ceiling); check `used_mb` beside `maxmemory_mb` in the run's log
Cache: the ceiling never grows	the working set fits the operator's ceiling	expected: a cache that fits has nothing for the ceiling to mend, and the row reads inside the noise
Storage-engine cache: the cache never fills, whatever the key space, and omni reads as a free memory saving	the benchmark's requests concentrate on a few hot records (YCSB's shipped zipfian draw), or the run asks for records the load did not write (hashed keys over an ordered load), so the reads are served from the index	a result that flatters the governor is the first thing to suspect: check "in cache" against the cache size in the per-notch lines; draw requests uniformly over the key space and name the same key order in load and run; a knob with nothing to do is not a saving
Storage-engine cache: the compass only ever reads calm	the line is set far above the stack's own latencies (a 2 ms line over 0.15 to 0.45 ms reads)	set the line on the tuning workload's own figures so that a hit is calm and a full-cache miss is slow, and write the figures in the preregistration before any counted

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Symptom	Cause	Fix
		run
Swarm: a cell reads "void"	two drones came within two collision radii in either arm	a task or simulator setting (keep-out, altitude stagger, depot spacing); fixed before any counted run and said in the preregistration
Three-run table heads itself with a warning	a run's commit is not the engine it claims, or the three are not separate runs	run `tools/omni_version.py --commit <sha>` on each; make the table only from runs on one frozen engine
Archive bot skips a run	the run was not finished when the bot passed, or the pass had taken its share of bytes	nothing to do: the next hourly pass copies it

APPENDIX

Appendix F. Evidence Map

`docs/EVIDENCE_LEDGER.md` (every claim and its class), `docs/CLAIMS_REGISTER.md` (what is claimed and what is not), `docs/GPU_PREREGISTRATION.md`, `docs/REALMS_PREREGISTRATION.md`, `docs/K8S_COMPASS_PREREGISTRATION.md`, `docs/POSTGRES_PREREGISTRATION.md`, `docs/KAFKA_PREREGISTRATION.md`, `docs/REDIS_PREREGISTRATION.md`, `docs/SWARM_PREREGISTRATION.md`, `docs/CITYLEARN_PREREGISTRATION.md`, `docs/PANDAPOWER_PREREGISTRATION.md`, `docs/ROBOTICS_PREREGISTRATION.md`, `docs/ROBUSTNESS_PREREGISTRATION.md`, `docs/YCSB_PREREGISTRATION.md` and `docs/MYSQL_PREREGISTRATION.md` (the rules written before each run), `docs/OMNI_V1.md` to `OMNI_V3.md` (every result by engine), `docs/REGISTER.md` (every benchmark and its file), `docs/PROOF_PROGRAM.md` (the program to full size with its costs), `docs/DOSSIER.md` (every result in one place), `results/OMNI_INDEX.md` (the one number), `docs/WIRING_VERDICTS.md` (which knobs earn a wire in, and every loss with its cause), `docs/STATE_OF_PLAY.md` (where everything stands), `docs/HANDOFF.md` (every command in one page).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

The map, claim by claim. Each claim this manual makes is listed here with the class of evidence behind it and the document that carries it, so that a reader can go from any sentence of the executive summary to the file that would have to be wrong for the sentence to be wrong.

Claim	Class	Where the evidence is	What would falsify it
The engine's six states stay inside their walls and settle	T / V (proof and test)	`docs/FORMAL_STATUS.md`, `docs/TRACKING_THEOREM.md`, `tests/`, `results/SOAK.json`	a trajectory leaving its wall, or the C++ twin disagreeing with the Python
No write ever leaves a knob's cover; a blind sense holds; fail-up is immediate	T / V	`tests/test_shield_properties.py` (two million cases), the plug tests per stack	one case of a write past the cover or a give-back while blind
On a real cluster the governor does more work inside the line, faster, on no more machines, at no more energy	L	the six Kubernetes tables in `results/live/`, A/B/C each, `docs/K8S_COMPASS_PREREGISTRATION.md`	a row LOSS in all three of our runs on work or speed, or power given on machines or energy with nothing bought in any of the six, which would stand in the table
Killed outright, the governor's settings are back at the operator's within seconds	L	`results/live/V11_ROBUST_KILL.md`, `docs/ROBUSTNESS_PREREGISTRATION.md`	a repetition handed back after 60 s, or not at all
Over two hours the governor neither leaks, slows nor drifts, and hands everything back at the end	L	`results/live/V11_ROBUST_LONG.md`, `docs/ROBUSTNESS_PREREGISTRATION.md`	memory growing past a quarter, the decision time growing past a half, fewer than 95% of expected decisions, or a setting not handed back
Governing costs a few thousandths of a core at every size	L	`results/live/V3_OWN_COST.md`	an own-cost figure growing with the organism
The pooler, the buffer pool and the storage-engine cache each give memory back on an untouched workload with no LOSS; the broker and the cache read nothing on the first set under the brain's verdict	L	`V3_PGBENCH.md`, `V3_KAFKA.md`, `V3_REDIS.md`, each preregistration	a product row LOSS in all three of our runs on an untouched workload; the memory row of the cache is such a loss and stands

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Claim	Class	Where the evidence is	What would falsify it
The one number: the Omni index across the real categories, each test's newest table, losses included	L, by rule	`results/OMNI_INDEX.md`, `tools/omni_index.py`	a category omitted, a loss not entered, a tuning row counted
A day of demand measured by someone else reads the same way as our own schedules	L	`results/live/V3_TRACE_GOOGLE2011.md`, `results/traces/google2011/schedule.json`, `docs/TRACES_PREREGISTRATION.md`	a schedule derived after the runs; a rule fitted to the governor; a trace part whose SHA-256 does not match
The modelled realms, grids, arms, buildings and swarms gain under their own native controllers	S	`results/realms/`, `V3_PANDAPOWER.md`, `V3_MUJOCO.md`, `V3_CITYLEARN.md`, `V3_SWARM.md`	a run of the same simulator at the same version and seed giving other digits
A physical meter shows less energy for the same work	P	**no current result**; `docs/GPU_PREREGISTRATION.md` names the run	the rerun on the current card controller reading no difference, or LOSS
Omni-Compass never changes the engine between a rule and its result	by construction	`OMNI_V3.json`, `tools/omni_version.py --commit <sha>` on every table's commits	a table whose runs' commits carry different fingerprints

What a referee asks of each document. Of a preregistration: is it dated before the first counted run, does it name the tuning case and the untouched cases, is every amendment dated and does any amendment made after a result was seen say so? Of a three-run table: are the three run ids separate runs, does the head name the engine at each commit, is every gauge of the preregistration present including the ones that went against the governor, and is the reading one of the three the rule allows? Of the index: is every real category in it, is every tuning row out of it, and does a loss in all three of our runs enter as a loss? Of the raw folder: does the SHA-256 manifest in it match the files, does the governor's audit show every decision with its reading and its write, and does the hand-back record read the operator's value? Every one of those questions has a yes in this program or a disclosure naming the exception; the disclosures are in section 60.14.

How to audit one result from this manual to its raw files. Take any row of Chapter 60. Its source column names a three-run table in `results/live/`; the table's head names the three GitHub run ids, the commit each ran on and the engine `tools/omni_version.py` reads at that commit. Each run id names a folder `results/live/raw/run-<id>/` (the branch `raw`, opened by `scripts/raw_archive.sh open /run-<id>/`) holding every repetition's files (the capture, the response times, the governor's audit and log,

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

the per-request records, one SHA-256 manifest per repetition). The table tool named in the table's text (`tools/confirm_abc.py` or its siblings) rebuilds the table from those folders; `tools/omni_index.py` rebuilds the index from the tables; `tools/dossier.py` rebuilds the dossier. The preregistration named in the table's text holds the rules, written before the first counted run, with every amendment dated. Nothing in that chain is by hand.

What one repetition leaves behind. Take the first repetition of the first kill-scenario run, archived at `results/live/raw/run-37716845219/paired-1/`. It holds two folders, one per arm, and the omni arm's folder holds twenty-nine files, every one of which a reader can open: `preflight.txt` (the UTC time, the arm, the git commit the arm ran at, the versions of Docker, kind, kubectl, the API server and Python, the metrics-server version with its SHA-256, the worker count and the probe's address); `rbac_omni.txt` (twenty lines of `kubectl auth can-i`, each verb the governor needs reading yes and each it must not have reading no); `window_start.txt` and `window_end.txt` (the window's clock); `load_schedule.log` (every load step and when it was applied); `latency.csv` (the probe's response times, one row a second); `capture.csv` (the cluster's state every fifteen seconds: replicas, workers, pods pending, the HPA's target); `host_cpu.csv` (the runner's own `/proc/stat`); `pod_watch.json` and `pods_end.json`, `nodes_end.txt`, `hpa_end.json` (the API server's own records at the end); `audit.jsonl` (one line per decision: the compass's position, heading and letter, the engine's state, every write with its value sent and its value read back); `controller.log` and `controller2.log` (the first governor's log, and the second one's after the kill); `audit_kill.jsonl` (the watchdog's restore writes, each with its command and its reason, such as "reset: remove record"); `watchdog.log` (one record: which governor, its process id, whether it was hung or dead, every command run and each exit code); `robust.log` (the kill at the 360th second with the settings as they stood, "target=50 range=1,10 limits=1850m 3700m workers=5/6", and the hand-back "every setting at the operator's after 8 s, target=50 limits=500m workers=6/6 left=none"); `rss.csv` (the governor's resident memory every fifteen seconds); `omni_writes.txt` (how many writes the governor made in the window: 42); `kill_switch.txt` (the reset check: target restored, workers in service, no record left); `omni2.pid` (the second governor's process id) and `kill` (the marker the harness wrote at the kill); `robust.out` (the same robustness log as the job printed it); `end_reads.err`, `pod_watch.err` and `capture.csv.errors` (empty, as they should be); `metrics-server-components.yaml` (the pinned manifest as applied); and `SHA256SUMS.txt`, one line per file. A reader who doubts a number in the kill table can find the second it was taken.

APPENDIX

Appendix G. The Muscles: What Each Is For, and How It Is Wired

A **muscle** is one setting on one machine that already has its own control: a replica target, a node pool's size, a GPU's clock ceiling, a chiller's setpoint, a battery's reserve, a joint's effort. Omni-Compass does not replace that control. It reads the machine's meters and, at its default, the max, moves the setting the machine already accepts toward the machine's own limit for the most work, never past it and never below native, through a plug that reads the setting once before the first write, reads back every write, steps aside if another controller moves it, and walks it back to native at the end. A knob native already runs at the top of its range is at its limit on native and is left there.

This chapter lists all 1107 muscles of the v5 catalog (`realms/catalog_v5.csv`); each run records its engine separately. For each one it says what kind of machine it is, which of the four kinds of knob it is, what Omni-Compass reads and does with it, how such a muscle is reached in a real stack, and which organisms it belongs to. The plants behind the benchmark numbers are models of these machines (evidence class **S**); a muscle in this list is wired on a real system only through the levels and the checks of the manual (chapters 4 and 6). See `DISCLOSURES.md`.

G.1 How to read an entry

The four kinds of knob.

- **capacity**: how much of the machine is in service (replicas, instances, units, speed). At the max Omni-Compass pushes it to the machine's own limit for the most work, never past it and never below native.
- **admission**: what is let in (queues, rate limits, admission control). Native already lets everything in: the knob is at its limit on native, and Omni-Compass reads it and leaves it native.
- **power**: the power share or limit the machine may draw. Native already runs it at full: at its limit on native, read and left native.
- **setpoint**: the target the machine's own loop holds (a temperature, a reserve, a process value). At the max a room is cooled ahead of the heat and a battery's charge is held for its line, inside the safe band, never behind native on its line.

The five kinds of plant. Every muscle is modelled on one of five plants, each with its own service reading and lever:

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Plant	What it is	What Omni-Compass reads	What Omni-Compass moves
`compute_pool`	a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs	how far its queue and its load sit toward the service line (queue or lateness, and load above half)	the capacity it may use: its replica or instance count (through its autoscaler's target or floor), its power share, or one unit given back through the release gate
`thermal_zone`	a data hall or building zone cooled by chillers, air handlers or fans	its temperature against its limit	its supply setpoint (colder is more cooling), its power share, or one cooling unit given back when the room has margin
`energy_storage`	a battery, UPS or microgrid store with a load and a grid connection	its draw on the grid connection and its reserve	its reserve setpoint (how much charge it holds back); its power limit is left native
`motion_axis`	a motor-driven axis: a robot joint, a flight-control surface, a reaction wheel, a traction motor	its tracking error and its load	its speed and effort share, or its power share
`process_loop`	a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint	how far the process sits from its band	its setpoint within its safe band, its actuator range, or its power share

Every muscle its own card. The brain is one, its settings each muscle's own. A muscle's card holds the settings the max uses for that muscle (a machine pool: how full it runs on its forecast before it calls for more, and how many decisions of history it reads; a battery: how many wobbles of margin it keeps under its line, and, wired by its power, how long it reads its line before it holds and how much of it it keeps clear). The cards were found by an automatic search over every muscle on the development seeds, today's global setting always one of the choices, and kept only where the card beat the global setting beyond the noise on two separate sets of seeds and on no seed under any load fell behind native: never over its line more often, never less work, never its line cleared later (`tools/tune_cards.py`, `realms/muscle_cards_v5.csv`, `results/cards_v5/`). Inside a body, a battery wired by its power keeps the body's own margins on its line. 364 muscles carry a card of their own; every other muscle runs the global setting (machines started at 95% full, the last 20 decisions read, 3.09 wobbles of margin on a battery's line, 5% of it kept clear). Each muscle's card is in the last column of its realm's table.

The organisms. The 1107 muscles build seven organisms: the spine (267 muscles, every muscle that sits in all four realms: the base every stack runs on, as an operating system is the base of every program), each of the four realms (every muscle whose realm list includes it, the spine among them), the four stacked with every

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

duplicate kept (1,908), and the whole tower with every muscle once (1107). Each is run native and with Omni-Compass on top of native (`docs/THE_SPINE.md`, `docs/REALMS.md`).

Organism	Muscles
The spine, the muscles every stack runs on	267
Compute / AI / Cloud	540
Physics / Robotics / Autonomous	404
Energy / Facility / Industrial	480
Distribution / Specialized	484
The four stacked, every duplicate kept	1,908
The whole tower, every muscle once	1107

How a muscle is reached in a real stack. The class of machine decides the wire:

Class of machine	What it is	The wire in a real stack
`batch`	batch and queued jobs	the job queue (Kubernetes Jobs, Slurm, Spark)
`batch_reactor`	a GMP batch reactor, fermenter or food process	the batch control system (ISA-88, OPC UA)
`building`	a building zone	the building management system
`chamber`	a controlled chamber (clean room, kiln, reactor)	the PLC or DCS
`clinical`	clinical systems: imaging archives, records, interface engines, monitoring gateways	the application's own scaling and admission settings (Kubernetes, the vendor console)
`commerce`	a customer-facing service with bursts	the Kubernetes API
`cpu_host`	a CPU host whose clock and power can be set	Linux cpufreq and RAPL
`data_hall`	a data hall cooling plant	the building management system (BACnet, Modbus) or its command line
`database`	a database cluster	the database operator (replicas, connection pools)
`district_heat`	a district heating or cooling network	the network control system and substation controllers (Modbus, M-Bus)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Class of machine	What it is	The wire in a real stack
`elevator_hoist`	an elevator or escalator drive and its group control	the lift controller and destination dispatch (modelled only)
`ev_traction`	an electric vehicle traction motor	the vehicle's motor controller (CAN; modelled only)
`fabric`	a high-speed fabric (RDMA, DPU, SmartNIC)	the fabric manager's API
`facility`	a facility battery behind the meter	the energy management system
`feeder_voltage`	a distribution feeder's voltage	the distribution management system (IEC 61850, DNP3; modelled only)
`flight_axis`	a flight-control axis	the flight controller (modelled only)
`gpu`	GPU serving with a response-time target	nvidia-smi (clock ceiling and power limit) or the serving autoscaler
`gpu_batch`	GPU training and batch work	nvidia-smi, the job scheduler's pause and resume
`hospital`	a hospital's critical rooms (operating rooms, isolation, pharmacy, imaging suites)	the hospital's building management system (BACnet)
`inverter`	a plant of grid-support inverters or wind turbines	the plant controller and inverter settings (SunSpec, IEC 61850, IEEE 1547)
`irrigation`	pumps, pressure and climate on a farm or in a greenhouse	the pump station controller, the pivot panel or the climate computer (Modbus, the vendor cloud)
`marine_propulsion`	a ship's propulsion shaft and power plant	the vessel automation and power management system (modelled only)
`microgrid`	a microgrid battery and loads	the inverter or energy management system (IEEE 2030.5, SunSpec, OpenADR)
`mill`	a grinding, flotation or materials-handling circuit	the plant DCS or PLC (OPC UA)
`network`	network routing and switching	the network controller (SDN, routing API)
`node`	a fleet of machines or VMs that boot in minutes	the node pool's size command (Karpenter, Cluster Autoscaler, MachineSet, cloud ASG)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Class of machine	What it is	The wire in a real stack
`pipeline`	a pipeline segment with its compressors, pumps and valves	pipeline SCADA (DNP3, Modbus, OPC UA)
`port`	a container terminal's cranes and vehicles taking moves	the terminal operating system and fleet controllers
`process`	an industrial process loop	the PLC or DCS (OPC UA, EtherNet/IP, PROFINET)
`qpu`	a quantum or specialised accelerator queue	the accelerator's job queue
`rail_traction`	a train's traction and auxiliary systems	the train control and management system and ATO (modelled only)
`ran`	a radio access network cell or site	the RAN controller (O-RAN interfaces)
`reaction_wheel`	a spacecraft reaction wheel	the attitude controller (modelled only)
`robot_fleet`	a fleet of robots or vehicles taking tasks	the fleet manager's dispatch API
`robot_joint`	a robot joint servo	the robot controller (ROS 2, EtherCAT, the drive's fieldbus)
`server`	an application service on servers or pods	the Kubernetes API (HPA target and floor, pod resize)
`storage`	block, file or object storage	the storage system's QoS and tiering API
`turbine`	a generating unit's governor, boiler or excitation loop	the plant DCS and governor (OPC UA, IEC 61850; modelled only)
`ups`	an uninterruptible power supply	the UPS and PDU management interface (SNMP, Modbus)
`water`	a water or pumping process	the SCADA system (Modbus, DNP3)
`workflow`	a workflow or pipeline engine	the workflow engine's concurrency settings

Wires marked *modelled only* exist as plants in the benchmark and are not built for live use.

How to wire any muscle on your own stack (the plug, chapter 4). Every muscle below is wired the same way: Omni-Compass never replaces the native controller; it reads the controller's own meters (the wire out) and writes the one setting the controller already accepts (the wire in), through a plug that (1) reads the setting once before the first write and records it, (2) reads back every write and stops writing if another writer moved the setting, (3) renews a lease every decision so a dead governor's settings walk back to native by themselves, and (4) restores the recorded setting at the end. Each family's entry says which native controller owns its

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

muscles, where the reading is tapped, where the setting is written, how it is restored, and whether that wire has run live in this repository or only on a model (`docs/wiring_recipes.csv`). The muscle's name is the setting's own name on that controller. Where the entry says *modelled only*, the plant exists in the benchmark and the wire is written against the controller's documented interface, not yet run on the machine.

G.2 The 1,107 muscles, heaviest hitters first, in the four realms they live in

Heaviest hitters first (the founder's order of 1 November): every list of the muscles is ordered by what Omni-Compass did for each muscle against native in the record of every muscle alone (`results/realms_v5/REALMS_V5.json`; our own models, evidence class S; omni-v8, run 2026-10-17 15:39 UTC, 10 seeds, both loads). First the muscles that take decisions back under their line, the largest share of all their decisions first (a decision over the line is a muscle past its own limit, the first harm do no harm names); then the muscles that clear the work waiting in line sooner, the most first; then the muscles that only add work; then the muscles the same as native; last the muscles at their limit on native, where Omni-Compass writes nothing; equal hits by the catalog's number. The four lists are the four realms, each muscle under its home realm, every muscle once (`tools/heavy_hitters.py`).

Each realm's table lists its home muscles (Compute / AI / Cloud 444, Physics / Robotics / Autonomous 137, Energy / Facility / Industrial 249, Distribution / Specialized 277; 1,107 in all), heaviest hitter first and down to its last. A muscle of the spine sits in all four realms: it is part of every realm's organism, counted once in the tower and four times in the stack, and listed once here, under its home realm. Its hit is the record's own reading of that muscle alone (omni-v8, class S): a model's reading of what the engine did there, never a benchmark result. How each family is wired on a real stack (its native controller, where the reading is tapped, where the setting is written, how it is restored) follows the four tables, the family with the heaviest hitter first.

G.2.1 Compute / AI / Cloud: 444 muscles, heaviest hitter first

G.3 How each family is wired, the family with the heaviest hitter first

Every family's muscles are wired the same way on a real stack; its muscles are named after its wire, heaviest hitter first, with each one's rank in its realm's table above.

G.3.1 Robotics Motion Control (26 muscles)

Each is a motor-driven axis: a robot joint, a flight-control surface, a reaction wheel, a traction motor; its class is `robot_joint` (a robot joint servo), reached through the robot controller (ROS 2, EtherCAT, the drive's fieldbus). Omni-Compass reads its tracking error and its load.

- **Native controller:** the robot's own controller: ros2_control and MoveIt parameters, the drive's limits over EtherCAT or the vendor fieldbus.
- **Wire out (read):** joint tracking error, effort, temperature, cycle time (joint_states, the drive's registers).
- **Wire in (write):** velocity and acceleration scaling, trajectory tolerances and controller rates through ROS 2 parameters (ros2 param set) or the drive's limit registers; never past the manufacturer's limits.
- **Restore:** every parameter read once (ros2 param get) and restored (ros2 param set).
- **Run live?** modelled: MuJoCo (results/live/V3_MUJOCO.md); the ROS 2 path is written, not yet run on a physical arm.
- **Its muscles, heaviest hitter first:** controller update rate (Physics 1), humanoid gait speed (Physics 2), jerk limit (Physics 3), velocity acceleration scaling (Physics 5), joint velocity (Physics 6), joint position (Physics 7), balance correction (Physics 8), humanoid step height (Physics 10), locomotion speed (Physics 12), trajectory tolerances (Physics 13), joint acceleration (Physics 14), manipulator payload speed scaling (Physics 15), humanoid balance margin (Physics 16), collision margin (Physics 18), ros2 executor threads (Physics 20), cartesian velocity (Physics 22), trajectory speed (Physics 23), trajectory acceleration (Physics 24), steering angle (Physics 26), ros2 qos history depth (Physics 54), ros2 control loop rate (Physics 55), joint effort (Physics 56), force limit (Physics 57), gripper force (Physics 58), braking force (Physics 59), humanoid joint torque limit (Physics 136).

All patents, copyrights and trademarks filed in the USA.

G.3.2 Automotive EV & Mobile Powertrain (14 muscles)

Each is a motor-driven axis: a robot joint, a flight-control surface, a reaction wheel, a traction motor; its class is `ev_traction` (an electric vehicle traction motor), reached through the vehicle's motor controller (CAN; modelled only). Omni-Compass reads its tracking error and its load.

- **Native controller:** the vehicle's motor and battery controllers (CAN, the OEM's diagnostic interface).
- **Wire out (read):** torque, speed, state of charge, temperatures (CAN signals).
- **Wire in (write):** torque, regeneration and charge limits within the OEM's envelope.
- **Restore:** recorded; restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** vehicle speed envelope (Physics 4), state of charge limits (Physics 90), smart charging schedule (Physics 91), traction torque limit (Physics 125), regen braking level (Physics 126), battery charge limit (Physics 127), battery discharge limit (Physics 128), battery thermal target (Physics 129), motor thermal limit (Physics 130), energy recovery target (Physics 131), auxiliary power budget (Physics 132), fast charge current (Physics 133), fast charge voltage (Physics 134), vehicle safe state (Physics 135).

G.3.3 Facility & Grid Optimization (15 muscles)

Each is a battery, UPS or microgrid store with a load and a grid connection; its class is `facility` (a facility battery behind the meter), reached through the energy management system. Omni-Compass reads its draw on the grid connection and its reserve.

- **Native controller:** the facility's energy management system and demand-response gateway (OpenADR).
- **Wire out (read):** site power, utility signals, PUE, carbon intensity (the EMS and the utility's feed).
- **Wire in (write):** the site power budget, demand limit and battery dispatch through the EMS.
- **Restore:** recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** site battery dispatch (Energy 1), renewable dispatch (Energy 2), generator start stop (Energy 3), facility peak guard (Energy 4), pue target (Energy 9), cooling power budget (Energy 21), facility power budget (Energy 30), utility demand limit (Energy 31), it power budget (Energy 32), rack power allocation (Energy 56), demand response (Energy 170), electricity price gate (Energy 171), carbon intensity gate (Energy 172), grid frequency response (Energy 173), facility islanding (Energy 174).

G.3.4 Energy Storage & Microgrid (19 muscles)

Each is a battery, UPS or microgrid store with a load and a grid connection; its class is `microgrid` (a microgrid battery and loads), reached through the inverter or energy management system (IEEE 2030.5, SunSpec, OpenADR). Omni-Compass reads its draw on the grid connection and its reserve.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Native controller:** the battery's or site's energy management system and inverter (SunSpec, IEEE 2030.5, OpenADR, Modbus).
- **Wire out (read):** state of charge, grid import and export, PV output, load (the EMS or inverter registers).
- **Wire in (write):** the reserve setpoint, charge and discharge limits, import limit and curtailment through SunSpec or Modbus registers.
- **Restore:** registers read once and restored.
- **Run live?** modelled: CityLearn (results/live/V3_CITYLEARN.md) for the districts; the register path is written.
- **Its muscles, heaviest hitter first:** volt var (Energy 5), storage dispatch (Energy 6), volt watt (Energy 7), peak shaving (Energy 8), microgrid emergency reserve (Energy 10), time of use schedule (Energy 11), battery soc reserve (Energy 12), electrolyzer power (Energy 13), heat pump power (Energy 14), pv curtailment (Energy 15), battery discharge power (Energy 16), battery charge power (Energy 18), grid export limit (Energy 25), ev charge power (Energy 27), grid import limit (Energy 28), constant power factor reactive power (Energy 29), microgrid demand limit (Energy 33), energy load shed (Energy 161), flex load admission (Energy 162).

G.3.5 Database & Transactions (19 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `database` (a database cluster), reached through the database operator (replicas, connection pools). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the database's own pooler and server settings: PgBouncer's admin console, MySQL SET GLOBAL, MongoDB setParameter, the database operator.
- **Wire out (read):** pool waits and active connections (SHOW POOLS), buffer-pool size and hit rate, cache size and evictions, p95 per statement.
- **Wire in (write):** PgBouncer default_pool_size through its console; MySQL innodb_buffer_pool_size by SET GLOBAL; MongoDB wiredTigerEngineRuntimeConfig cache_size by setParameter; replicas through the operator.
- **Restore:** the setting read once before the first write and restored; a failed read-back stops the writer.
- **Run live?** live: tools/run_pgbench.py, run_sysbench.py, run_ycsb.py, three-run tables V3_PGBENCH, V3_SYSBENCH, V3_YCSB.
- **Its muscles, heaviest hitter first:** io capacity (Distribution 1), vacuum compaction rate (Distribution 2), read route (Distribution 3), db failover (Distribution 4), db cache (Distribution 5), db pool resize (Distribution 7), shard placement (Distribution 8), db replicas (Distribution 9), db memory (Distribution 10), checkpoint rate (Distribution 11), buffer pool (Distribution 16), background writer (Distribution 17), synchronous replication (Distribution 18), parallel workers (Distribution 19), query concurrency

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(Distribution 197), replication lag gate (Distribution 198), db write throttle (Distribution 199), transaction concurrency (Distribution 200), lock timeout (Distribution 201).

G.3.6 Commerce & Payment Systems (15 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `commerce` (a customer-facing service with bursts), reached through the Kubernetes API. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the payment platform's gateway and its routing rules.
- **Wire out (read):** authorisation latency, decline and retry rates, queue depth (the platform's metrics).
- **Wire in (write):** concurrency, timeout and route weights through the platform's admin API.
- **Restore:** recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** payment failover (Distribution 6), settlement batch (Distribution 12), order reservation (Distribution 13), authorization route (Distribution 14), processor route weight (Distribution 15), idempotency window (Distribution 20), refund queue rate (Distribution 21), payment admission (Distribution 236), payment concurrency (Distribution 237), payment retry (Distribution 238), payment timeout (Distribution 239), fraud review gate (Distribution 240), transaction queue limit (Distribution 241), inventory hold (Distribution 242), checkout load shed (Distribution 243).

G.3.7 Aviation & Autonomous Flight (28 muscles)

Each is a battery, UPS or microgrid store with a load and a grid connection; its class is `microgrid` (a microgrid battery and loads), reached through the inverter or energy management system (IEEE 2030.5, SunSpec, OpenADR). Omni-Compass reads its draw on the grid connection and its reserve.

- **Native controller:** the flight controller's own parameters: PX4 (MPC_XY_VEL_MAX, MPC_Z_VEL_MAX_UP, MPC_ACC_HOR, MC_ROLLRATE_MAX) and ArduPilot (WPNAV_SPEED, ATC_ACCEL_R_MAX), the battery failsafe.
- **Wire out (read):** mission progress, battery state, tracking error and near-miss distance over MAVLink telemetry.
- **Wire in (write):** the speed, acceleration and rate parameters over MAVLink PARAM_SET within the autopilot's own limits; failsafes and geofence never loosened.
- **Restore:** every parameter read (PARAM_REQUEST_READ) once and written back at the end.
- **Run live?** modelled: the swarm cells (results/live/V3_SWARM.md); the MAVLink path is written, not yet flown.
- **Its muscles, heaviest hitter first:** drone battery failsafe reserve (Physics 9), swarm formation spacing (Physics 17), ardupilot wpnav speed (Physics 21), px4 mpc xy vel max (Physics 25), px4 mpc acc hor (Physics 37), altitude target (Physics 38), waypoint authority (Physics 39), px4 mc rollrate max (Physics 40), actuator saturation envelope (Physics 41), px4 mpc z vel max up (Physics 42), velocity target

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(Physics 43), attitude rate target (Physics 44), attitude target (Physics 45), attitude rate gains (Physics 46), throttle envelope (Physics 63), flight hold (Physics 64), return to home (Physics 65), land action (Physics 66), mission admission (Physics 67), geofence response (Physics 68), failsafe selection (Physics 69), battery reserve threshold (Physics 70), flight mode transition (Physics 71), flight termination safe state (Physics 72), horizontal speed limit (Physics 87), vertical speed limits (Physics 88), acceleration jerk limits (Physics 89), ardupilot atc accel r max (Physics 137).

G.3.8 Robotics Fleet & Warehouse Automation (17 muscles)

Each is a battery, UPS or microgrid store with a load and a grid connection; its class is `microgrid` (a microgrid battery and loads), reached through the inverter or energy management system (IEEE 2030.5, SunSpec, OpenADR). Omni-Compass reads its draw on the grid connection and its reserve.

- **Native controller:** the fleet manager's dispatch and charging rules (Open-RMF, the vendor fleet manager).
- **Wire out (read):** tasks waiting, robots active and charging, battery states (the fleet API).
- **Wire in (write):** active robot count, charge thresholds and zone admission through the fleet API.
- **Restore:** recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** amr fleet charge threshold (Physics 11), agv speed (Physics 30), conveyor speed (Physics 31), task assignment (Physics 32), traffic reservation (Physics 33), elevator request (Physics 34), amr fleet active robots (Physics 35), robot route (Physics 36), battery reserve (Physics 47), robot dispatch (Physics 48), human safe stop (Physics 50), door request (Physics 51), charging dispatch (Physics 52), fleet failover (Physics 53), warehouse zone admission (Physics 60), robot quarantine (Physics 61), fleet concurrency (Physics 62).

G.3.9 Cloud VM & Capacity (21 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `node` (a fleet of machines or VMs that boot in minutes), reached through the node pool's size command (Karpenter, Cluster Autoscaler, MachineSet, cloud ASG). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the cloud's autoscaling group or scale set: AWS Auto Scaling, Azure VMSS, GCP MIG.
- **Wire out (read):** group size, instance states, the target-tracking metric (the cloud's API and monitoring).
- **Wire in (write):** desired capacity, min and max, the target-tracking policy's target, through the cloud CLI or SDK.
- **Restore:** the group's desired, min, max and policy recorded once; restored from it.
- **Run live?** live on AKS through the node pool (family 5); the cloud SDK path itself is written, not yet run live.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Its muscles, heaviest hitter first:** architecture selection (Compute 1), accelerator selection (Compute 5), instance refresh (Compute 7), vm start stop (Compute 19), region selection (Compute 31), placement group (Compute 33), vm migrate (Compute 34), asg max (Compute 38), zone selection (Compute 39), interruption response (Compute 51), vm size (Compute 53), target tracking policy (Compute 54), spot mix (Compute 57), instance family (Compute 67), boot disk class (Compute 70), scaling cooldown warmup (Compute 71), vm count (Compute 82), predictive scaling (Compute 87), asg min (Compute 91), reservation mix (Compute 110), vm cpu cap by priority (Compute 400).

G.3.10 Kubernetes Dynamic Device Allocation (8 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `gpu` (GPU serving with a response-time target), reached through nvidia-smi (clock ceiling and power limit) or the serving autoscaler. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** Kubernetes DRA: DeviceClass, ResourceClaim, ResourceSlice.
- **Wire out (read):** claims pending, devices allocated and tainted (the Kubernetes API).
- **Wire in (write):** DeviceClass selectors and claim capacity by kubectl apply; devices tainted, never removed.
- **Restore:** the objects recorded; restored.
- **Run live?** modelled; the API path is kubectl.
- **Its muscles, heaviest hitter first:** dra claim capacity (Compute 2), dra binding readiness (Compute 13), dra binding failure response (Compute 14), dra device class selection (Compute 50), dra device configuration (Compute 61), dra claim sharing (Compute 76), dra device taint (Compute 84), dra device eviction (Compute 412).

G.3.11 Cross-Cluster, Multi-Region & Edge (18 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `node` (a fleet of machines or VMs that boot in minutes), reached through the node pool's size command (Karpenter, Cluster Autoscaler, MachineSet, cloud ASG). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the global load balancer and the fleet manager (Karmada, Fleet, the cloud's global LB).
- **Wire out (read):** per-region latency, capacity and cost, pending work (the global LB's and clusters' metrics).
- **Wire in (write):** region and cluster weights and quotas through the global controller's API.
- **Restore:** recorded; restored.
- **Run live?** modelled.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Its muscles, heaviest hitter first:** global failover (Compute 3), edge site node pool (Compute 11), edge offload (Compute 12), zone dispatch (Compute 15), cloud capacity class (Compute 28), workload migrate region (Compute 29), region dispatch (Compute 32), edge dispatch (Compute 37), multi cluster dispatch (Compute 40), cross cluster replication (Compute 49), edge sync interval (Compute 298), data residency gate (Compute 379), latency region gate (Compute 380), cost region gate (Compute 381), carbon region gate (Compute 382), federation quota (Compute 383), global admission (Compute 384), edge inference gpu clocks (Compute 444).

G.3.12 AI Inference Serving (24 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `gpu` (GPU serving with a response-time target), reached through nvidia-smi (clock ceiling and power limit) or the serving autoscaler. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the serving engine's own autoscaler and batcher (vLLM, Triton, KServe, Ray Serve): replicas, batch size, concurrency, KV cache.
- **Wire out (read):** queue depth, tokens per second, p95 latency, KV-cache use from the server's /metrics.
- **Wire in (write):** the server's replica count or KServe/Knative autoscaling target, max_num_seqs and KV-cache budget through its API or its ConfigMap.
- **Restore:** the serving spec recorded once; restored to it.
- **Run live?** live in part: GPU serving under the card governor (results/gpu); the vLLM run is ready and waits on Lambda.
- **Its muscles, heaviest hitter first:** lora adapter load (Compute 4), continuous batching (Compute 8), model replicas (Compute 16), model instance count (Compute 17), max batch size (Compute 18), tensor parallel degree (Compute 35), batch queue delay (Compute 42), model route weight (Compute 45), chunked prefill (Compute 60), kv cache swap space (Compute 63), inference max tokens (Compute 77), disaggregated prefill decode (Compute 85), model load (Compute 86), model unload (Compute 93), scale to zero panic window (Compute 101), inference concurrency (Compute 352), kv cache budget (Compute 353), prefix cache budget (Compute 354), speculative decode budget (Compute 355), model precision (Compute 356), inference priority (Compute 357), inference slo gate (Compute 358), autoscaling target concurrency qps (Compute 395), request priority levels (Compute 396).

G.3.13 GPU Hardware (22 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `gpu` (GPU serving with a response-time target), reached through nvidia-smi (clock ceiling and power limit) or the serving autoscaler. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the card's own firmware limits through NVML and nvidia-smi (power limit, application clocks, MIG, compute mode).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Wire out (read):** nvidia-smi --query-gpu (clocks, power draw, temperature, utilisation, memory), the serving response time from the probe.
- **Wire in (write):** nvidia-smi -pl (power limit), -lgc/-rgc (clock ceiling and reset), -ac (application clocks), -mig and -c (modes), per card.
- **Restore:** every limit read once at start (the snapshot line in the GPU audit) and restored by the same commands at the end or on the lease.
- **Run live?** live: omni_controller/gpu_governor.py and scripts/gpu_paired.sh on a rented A10 (results/gpu); the new card runs wait on Lambda by the founder's order.
- **Its muscles, heaviest hitter first:** sync boost (Compute 6), gpu persistence mode (Compute 43), mig mode (Compute 44), gpu mps (Compute 72), gpu timeslice (Compute 74), gpu allocate (Compute 78), mig geometry (Compute 79), gpu ecc response (Compute 80), gpu compute mode (Compute 83), gpu temperature target (Compute 88), gpu reset (Compute 99), gpu power limit (Compute 342), gpu sm clock (Compute 343), gpu memory clock (Compute 344), gpu quarantine (Compute 345), gpu thermal limit (Compute 346), gpu job power budget (Compute 347), application clocks (Compute 394), target clocks (Compute 403), climatik inference power cap (Compute 406), adaptive gpu power cap (Compute 410), nvidia platform power budget (Compute 411).

G.3.14 Node Fleet & Karpenter-Class Control (24 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `node` (a fleet of machines or VMs that boot in minutes), reached through the node pool's size command (Karpenter, Cluster Autoscaler, MachineSet, cloud ASG). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the cluster's own node autoscaler: Karpenter (NodePool), the Cluster Autoscaler, a MachineSet, a cloud node pool.
- **Wire out (read):** ready and schedulable workers, pending pods, allocatable and used CPU (Kubernetes API), the autoscaler's status ConfigMap.
- **Wire in (write):** the pool's size through the operator's own command (--node-scale-cmd: az aks nodepool scale, gcloud container clusters resize, eksctl scale nodegroup, kubectl scale machineset, a Karpenter NodePool limit); a machine parked by taint and drain, never deleted by Omni-Compass.
- **Restore:** the pool's starting count recorded once; every parked machine untainted and the pool restored to it at the end or on the lease.
- **Run live?** live: omni_controller nodepool mode on kind and on AKS (results/live/V1_AKS_*, the capacity and steady tables).
- **Its muscles, heaviest hitter first:** nodepool weight (Compute 9), node shutdown (Compute 21), max pods per node (Compute 22), node provision (Compute 23), node consolidate (Compute 24), node pool min (Compute 25), node pool max (Compute 36), expander (Compute 47), capacity class (Compute 52), consolidate after (Compute 55), scale down unneeded time (Compute 56), node replace (Compute 62),

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

node desired (Compute 64), kubelet reserved resources (Compute 66), consolidation policy (Compute 68), node power on (Compute 73), node pool limits (Compute 75), expire after (Compute 81), scale down delay after add (Compute 90), node cordon (Compute 326), node drain (Compute 327), disruption budget (Compute 328), scale down utilisation threshold (Compute 390), kubelet eviction thresholds (Compute 391).

G.3.15 Virtualization & Hypervisor (9 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `node` (a fleet of machines or VMs that boot in minutes), reached through the node pool's size command (Karpenter, Cluster Autoscaler, MachineSet, cloud ASG). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the hypervisor's management API (libvirt, vSphere, Hyper-V).
- **Wire out (read):** vCPU steal, balloon state, migration load (the hypervisor's metrics).
- **Wire in (write):** vCPU allocation, ballooning and migration pacing through the management API.
- **Restore:** recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** vm overcommit density (Compute 10), vgpu partition (Compute 46), hypervisor cpu pinning (Compute 89), vcpu allocation (Compute 142), memory ballooning (Compute 166), sriov vf allocation (Compute 212), numa vcpu pinning (Compute 284), live migration pacing (Compute 420), vm memory dedup ksm (Compute 421).

G.3.16 Medical Imaging & Clinical Systems (12 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `clinical` (clinical systems: imaging archives, records, interface engines, monitoring gateways), reached through the application's own scaling and admission settings (Kubernetes, the vendor console). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the clinical application's own scaling and admission settings (Kubernetes, the vendor console).
- **Wire out (read):** queue depths, interface backlog, reconstruction wait (the application's metrics).
- **Wire in (write):** replicas, concurrency and rate limits through the Kubernetes API or the vendor console.
- **Restore:** recorded; restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** ehr application replicas (Distribution 22), pacs archive tier target (Distribution 24), reconstruction gpu workers (Distribution 26), dicom router concurrency (Distribution 252), hl7 interface queue limit (Distribution 253), fhir api rate limit (Distribution 254), modality worklist timeout (Distribution 255), patient monitoring gateway capacity (Distribution 256), lab analyzer batch

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

window (Distribution 257), telehealth session admission (Distribution 258), clinical backup window (Distribution 259), imaging prefetch priority (Distribution 260).

G.3.17 Financial Markets & Trading Systems (14 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `node` (a fleet of machines or VMs that boot in minutes), reached through the node pool's size command (Karpenter, Cluster Autoscaler, MachineSet, cloud ASG). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the trading platform's gateway, matching engine and risk settings, the colocation BMS.
- **Wire out (read):** order latency, session counts, risk-check backlog, market-data fanout (the platform's metrics).
- **Wire in (write):** thread and session pools, conflation intervals and batch sizes through the platform's configuration; risk checks never relaxed.
- **Restore:** recorded; restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** backtest grid nodes (Distribution 23), order gateway sessions (Distribution 67), pre trade risk check workers (Distribution 80), matching engine threads (Distribution 81), market data fanout threads (Distribution 124), surveillance alert queue workers (Distribution 144), post trade settlement workers (Distribution 157), market data conflation interval (Distribution 173), fix session heartbeat interval (Distribution 174), tick store write batch (Distribution 175), colocation rack cooling setpoint (Distribution 176), order admission rate limit (Distribution 273), kernel bypass poll cores (Distribution 274), end of day risk batch power (Distribution 275).

G.3.18 Game Servers & Real-Time Interactive (12 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `node` (a fleet of machines or VMs that boot in minutes), reached through the node pool's size command (Karpenter, Cluster Autoscaler, MachineSet, cloud ASG). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** Agones Fleets and the matchmaker, the game node pool.
- **Wire out (read):** allocated and ready servers, matchmaking waits, tick rate (Agones and the matchmaker's metrics).
- **Wire in (write):** Fleet replicas and buffer sizes by kubectl patch; matchmaking admission through its API.
- **Restore:** the Fleet spec recorded; restored.
- **Run live?** modelled; the API path is kubectl patch.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Its muscles, heaviest hitter first:** agones fleet max replicas (Compute 20), game node pool autoscaler (Compute 41), voice chat mixer pool (Compute 158), agones fleet buffer size (Compute 162), agones fleet min replicas (Compute 165), relay server pool (Compute 198), replay render batch (Compute 268), game server tick rate (Compute 293), matchmaking wait window (Compute 294), players per server cap (Compute 435), matchmaking admission rate (Compute 436), cloud gaming gpu clocks (Compute 437).

G.3.19 CI/CD & Build Farms (10 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `node` (a fleet of machines or VMs that boot in minutes), reached through the node pool's size command (Karpenter, Cluster Autoscaler, MachineSet, cloud ASG). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the runner scale set (actions-runner-controller, GitLab runners) and the build cache.
- **Wire out (read):** jobs queued, runners busy, cache hit rate (the controller's metrics).
- **Wire in (write):** min and max runners, build concurrency and cache size by kubectl patch of the scale set.
- **Restore:** the scale set spec recorded; restored.
- **Run live?** modelled; the API path is kubectl patch.
- **Its muscles, heaviest hitter first:** warm runner pool (Compute 26), runner scale set max runners (Compute 30), build cache size (Compute 214), test shard parallelism (Compute 258), runner scale set min runners (Compute 259), remote execution workers (Compute 262), artifact retention ttl (Compute 297), build concurrency limit (Compute 441), job queue admission (Compute 442), build node cpu frequency (Compute 443).

G.3.20 OpenShift & Machine API (9 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `node` (a fleet of machines or VMs that boot in minutes), reached through the node pool's size command (Karpenter, Cluster Autoscaler, MachineSet, cloud ASG). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** OpenShift's Machine API operators: MachineHealthCheck, MachineConfigPool, the Cluster Version Operator.
- **Wire out (read):** machine phases, MCP status and pause, degraded counts (the OpenShift API).
- **Wire in (write):** MachineHealthCheck maxUnhealthy, MachineConfigPool paused and maxUnavailable by oc patch.
- **Restore:** the fields recorded before the first write, restored from the record.
- **Run live?** modelled; written against the documented OpenShift API, not yet run live.
- **Its muscles, heaviest hitter first:** node config rollout (Compute 27), machine remediation (Compute 48), mcp max unavailable (Compute 59), cluster version pacing (Compute 69), machine failure domain

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

(Compute 92), machine health gate (Compute 329), mcp pause (Compute 330), operator reconcile budget (Compute 331), infra machine admission (Compute 332).

G.3.21 Messaging & Streaming (22 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `node` (a fleet of machines or VMs that boot in minutes), reached through the node pool's size command (Karpenter, Cluster Autoscaler, MachineSet, cloud ASG). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the broker's own controls: Kafka's admin API and consumer group, RabbitMQ policies, MQTT broker settings.
- **Wire out (read):** consumer lag, messages per second, p95 end to end, broker CPU (the broker's metrics, the consumer group's offsets).
- **Wire in (write):** the consumer group's size (consumers running), quotas and partition counts through the admin API.
- **Restore:** the group's size recorded; restored at the end.
- **Run live?** live: tools/run_kafka.py, V3_KAFKA.
- **Its muscles, heaviest hitter first:** broker cluster nodes (Distribution 25), fetch batch size (Distribution 31), rebalance rate (Distribution 47), broker failover (Distribution 50), dead letter divert (Distribution 54), replication factor (Distribution 69), partition count (Distribution 71), producer batch size (Distribution 74), message retention (Distribution 78), partition placement (Distribution 92), prefetch (Distribution 103), memory disk alarm (Distribution 107), mqtt broker max connections (Distribution 110), mqtt max inflight messages (Distribution 178), mqtt session expiry (Distribution 179), producer quota (Distribution 202), consumer quota (Distribution 203), broker io quota (Distribution 204), queue depth limit (Distribution 205), consumer concurrency (Distribution 206), retry backoff (Distribution 207), stream priority (Distribution 208).

G.3.22 Quantum Computing Control Simulation (16 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `qpu` (a quantum or specialised accelerator queue), reached through the accelerator's job queue. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the quantum control stack's job queue and pulse schedules (Qiskit Runtime, the vendor's control software).
- **Wire out (read):** queue depth, calibration drift, error rates (the stack's metrics).
- **Wire in (write):** shot allocation, circuit admission and scheduling through the stack's API; pulse parameters never written live.
- **Restore:** recorded; restored.
- **Run live?** modelled only.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Its muscles, heaviest hitter first:** pulse phase (Compute 58), measurement scheduling (Compute 65), reset scheduling (Compute 163), gate scheduling (Compute 167), pulse duration (Compute 181), qubit mapping (Compute 188), dynamical decoupling (Compute 193), shot allocation (Compute 194), noise aware routing (Compute 196), coupling control (Compute 201), pulse amplitude (Compute 211), circuit admission (Compute 374), circuit scheduling (Compute 375), pulse frequency (Compute 376), error mitigation budget (Compute 377), quantum queue priority (Compute 378).

G.3.23 Service Mesh & API Reliability (16 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the mesh's own policies: Istio DestinationRule and VirtualService, Linkerd ServiceProfile, Envoy filters.
- **Wire out (read):** request rate, error rate, p95 and outlier ejections from the mesh's telemetry.
- **Wire in (write):** connection pool, outlier detection, retry budget and traffic weights by kubectl patch of the policy objects.
- **Restore:** the policy objects recorded; restored.
- **Run live?** modelled; the API path is kubectl patch.
- **Its muscles, heaviest hitter first:** service failover (Distribution 27), canary weight (Distribution 40), dns traffic weight (Distribution 41), load balancing policy (Distribution 49), traffic mirror (Distribution 62), session affinity (Distribution 66), traffic divert (Distribution 68), request hedging (Distribution 88), connection pool (Distribution 130), circuit breaker (Distribution 188), retry budget (Distribution 189), service timeout (Distribution 190), service concurrency (Distribution 191), outlier ejection (Distribution 192), health threshold (Distribution 193), fault injection gate (Distribution 194).

G.3.24 PDU, UPS & Electrical Distribution (18 muscles)

Each is a battery, UPS or microgrid store with a load and a grid connection; its class is `ups` (an uninterruptible power supply), reached through the UPS and PDU management interface (SNMP, Modbus). Omni-Compass reads its draw on the grid connection and its reserve.

- **Native controller:** the UPS and PDU management interfaces (SNMP, Modbus) and the servers' BMC power caps (IPMI DCMI, Redfish).
- **Wire out (read):** load per branch, UPS mode and charge, power per server (SNMP, Redfish).
- **Wire in (write):** server and rack power caps through Redfish or DCMI; UPS charge rate and mode through SNMP; breakers never written.
- **Restore:** every cap and mode read once and restored.
- **Run live?** modelled.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Its muscles, heaviest hitter first:** pdu outlet control (Energy 17), phase balance (Energy 19), generator dispatch (Energy 20), ups shutdown battery test (Energy 22), ups operating mode (Energy 23), reactive power target (Energy 24), voltage target (Energy 26), server power cap (Energy 40), rack power cap (Energy 41), pdu branch power limit (Energy 42), ups charge rate (Energy 43), ups discharge rate (Energy 44), hierarchical power budget row pdu switchboard controllers (Energy 62), priority aware capping throttle low priority first (Energy 63), power oversubscription with prediction (Energy 64), load transfer (Energy 163), electrical isolation (Energy 164), breaker trip gate (Energy 165).

G.3.25 Runtime & Application (21 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the application runtime's own settings: thread pools, JVM heap and GC, worker counts, connection pools.
- **Wire out (read):** queue waits, GC pauses, worker busy share, p95 from the application's metrics.
- **Wire in (write):** worker and pool sizes through the application's admin endpoint, environment or config reload; JVM flags at restart only.
- **Restore:** the settings recorded; restored (a restart-bound setting is left native).
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** background workers (Distribution 28), runtime memory (Distribution 29), thread pool (Distribution 30), go runtime (Distribution 34), event loop workers (Distribution 36), jvm heap (Distribution 52), process count (Distribution 55), keepalive connection reuse (Distribution 56), application cache size (Distribution 58), worker count (Distribution 89), runtime restart (Distribution 93), connection pool runtime (Distribution 95), dns resolver cache size (Distribution 123), mail queue concurrency (Distribution 139), dns negative cache ttl (Distribution 180), mail retry interval (Distribution 181), gc budget (Distribution 222), async concurrency (Distribution 223), request timeout (Distribution 224), runtime cpu budget (Distribution 225), runtime io budget (Distribution 226).

G.3.26 Marine Propulsion & Vessel Automation (12 muscles)

Each is a motor-driven axis: a robot joint, a flight-control surface, a reaction wheel, a traction motor; its class is `marine_propulsion` (a ship's propulsion shaft and power plant), reached through the vessel automation and power management system (modelled only). Omni-Compass reads its tracking error and its load.

- **Native controller:** the vessel's automation and power management system.
- **Wire out (read):** shaft speed and power, fuel rate, engine load (the automation system).
- **Wire in (write):** shaft speed and power limits, engine staging within the manufacturer's envelope.
- **Restore:** recorded; restored.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** shaft speed target (Physics 19), engine load sharing setpoint (Physics 27), trim target (Physics 28), auxiliary engine staging (Physics 29), slow steaming speed target (Physics 49), propeller pitch limit (Physics 106), shaft power limit (Physics 107), bow thruster duty (Physics 108), ballast pump mode (Physics 109), shore power mode (Physics 110), hotel load budget (Physics 111), rudder rate limit (Physics 112).

G.3.27 Serverless & Functions (FaaS) (9 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the function platform's concurrency settings (Knative autoscaling annotations, AWS Lambda concurrency, OpenFaaS).
- **Wire out (read):** concurrency, cold starts, queue waits (the platform's metrics).
- **Wire in (write):** provisioned and reserved concurrency, scale-to-zero windows through the platform's API or annotations.
- **Restore:** recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** fn snapstart restore (Compute 94), fn provisioned concurrency (Compute 123), fn prewarm pool (Compute 128), fn reserved concurrency (Compute 129), fn memory size (Compute 145), fn concurrency limit (Compute 186), fn timeout budget (Compute 283), fn scale to zero idle (Compute 418), fn burst admission (Compute 419).

G.3.28 Kubernetes Placement & Scheduling (21 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** kube-scheduler and its profiles, the descheduler, PriorityClasses, scheduling gates.
- **Wire out (read):** pods pending and their reasons, node fill, topology spread (Kubernetes API).
- **Wire in (write):** a pod's or deployment's placement fields (nodeSelector, affinity, topologySpreadConstraints, priorityClassName, schedulingGates) by kubectl patch, or the scheduler's profile.
- **Restore:** the fields as they stood before the first write, restored field by field.
- **Run live?** modelled; the API path is the same kubectl patch the live controller uses for the HPA.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Its muscles, heaviest hitter first:** deschedule (Compute 95), cpu manager (Compute 96), peaks power aware placement (Compute 100), scheduler scoring strategy (Compute 105), topology spread (Compute 106), pod anti affinity (Compute 120), taint toleration (Compute 126), device claim (Compute 127), scheduler plugin weights (Compute 140), numa placement (Compute 141), network locality (Compute 147), gpu topology (Compute 169), storage locality (Compute 175), node selector (Compute 176), failure domain spread (Compute 182), node affinity (Compute 197), priority class (Compute 322), preemption policy (Compute 323), scheduler backoff (Compute 324), gang admission (Compute 325), scheduling gates (Compute 389).

G.3.29 Observability & Telemetry (9 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the collector's own configuration: the OpenTelemetry Collector, Prometheus scrape and remote-write settings.
- **Wire out (read):** dropped samples, queue depth, memory, cardinality (the collector's self-metrics).
- **Wire in (write):** the collector's batch, queue and memory limits and scrape intervals through its config reload.
- **Restore:** the config recorded; reloaded from it.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** collector memory limit (Distribution 32), per pod energy attribution (Distribution 39), retention window (Distribution 53), remote write queue (Distribution 82), metric scrape interval (Distribution 90), batching (Distribution 102), export concurrency (Distribution 227), cardinality budget (Distribution 228), telemetry shed (Distribution 229).

G.3.30 Reliability, Security & Recovery (18 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the platform's own recovery and security controls: rollout and rollback, PodDisruptionBudgets, the security hold, a kill switch.
- **Wire out (read):** error rate, rollout status, the security hold (a ConfigMap key), the kill file.
- **Wire in (write):** rollout pause and undo by kubectl; the security hold read, never written; the kill switch (tools/omni_switch.py) is a human's.
- **Restore:** every write recorded and undone on the lease.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Run live?** live in part: the security hold and kill switch run in every Kubernetes benchmark (omnicompass/master.py).
- **Its muscles, heaviest hitter first:** degraded mode (Distribution 33), backup trigger (Distribution 46), waf inspection workers (Distribution 59), traffic divert recovery (Distribution 70), rollback (Distribution 73), policy enforcement (Distribution 83), restart (Distribution 101), ids capture threads (Distribution 127), siem ingest pipeline workers (Distribution 148), ids ring buffer size (Distribution 177), actuator freeze (Distribution 230), workload isolate (Distribution 231), credential rotation gate (Distribution 232), rate abuse gate (Distribution 233), fault domain isolate (Distribution 234), kill switch (Distribution 235), ids rule group admission (Distribution 276), endpoint scan scheduling (Distribution 277).

G.3.31 Kubernetes Workload Scaling (32 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the HorizontalPodAutoscaler, KEDA ScaledObject or VPA that owns the workload's scale.
- **Wire out (read):** the HPA's current and desired replicas, the Deployment's ready replicas (Kubernetes API, metrics-server), the service's response time from the probe.
- **Wire in (write):** the HPA's target (spec.metrics averageUtilization) and floor (minReplicas) by kubectl patch; KEDA through its ScaledObject, so the add-on keeps its own loop.
- **Restore:** the operator's target and range recorded in an annotation before the first write, restored from it, annotation removed.
- **Run live?** live: scripts/kind_bench.sh and omni_controller (HPA target, KEDA, Goldilocks, CruiseKube), three-run tables in results/live.
- **Its muscles, heaviest hitter first:** vpa minmax allowed resources (Compute 97), hpa cpu target (Compute 98), rollout rate (Compute 104), hpa custom target (Compute 107), hpa scale down stabilisation window (Compute 108), max surge (Compute 111), vpa apply (Compute 117), replicas (Compute 125), keda polling interval (Compute 130), graceful termination (Compute 131), scale to zero (Compute 137), hpa scale up stabilisation window (Compute 144), rollout readiness delay (Compute 148), hpa memory target (Compute 149), probes (Compute 154), hpa scaling rate policies (Compute 157), hpa max replicas (Compute 161), pdb policy (Compute 164), hpa min replicas (Compute 170), kepler energy target autoscaling (Compute 171), hpa policy selection (Compute 177), hpa tolerance (Compute 180), hpa sync period (Compute 189), max unavailable (Compute 190), keda threshold (Compute 315), deployment pause resume (Compute 316), rollout abort (Compute 317), pod eviction (Compute 318), scheduler queue priority (Compute 319), api priority fairness (Compute 320), rollout progress deadline (Compute 385), unhealthy pod eviction policy (Compute 386).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

G.3.32 Cache & Memory Services (16 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the cache's own configuration: Redis CONFIG SET, Memcached runtime settings.
- **Wire out (read):** hit rate, evictions, used memory, p95 (INFO, the cache's stats).
- **Wire in (write):** maxmemory and eviction policy by CONFIG SET; replicas and shards through the operator.
- **Restore:** the setting read once (CONFIG GET) before the first write and restored (CONFIG SET).
- **Run live?** live: tools/run_redis.py, V3_REDIS.
- **Its muscles, heaviest hitter first:** cache size (Distribution 35), cache failover (Distribution 38), cache sharding (Distribution 42), cache replicas (Distribution 45), cache writeback rate (Distribution 51), cache ttl (Distribution 57), memory size threads (Distribution 61), cache prefetch (Distribution 65), cache memory limit (Distribution 86), cache compression (Distribution 94), cache warmup (Distribution 96), cache flush rate (Distribution 98), cache eviction policy (Distribution 209), cache admission (Distribution 210), hot key isolation (Distribution 211), cache connection limit (Distribution 212).

G.3.33 Search, Indexing & Vector DB (16 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the search engine's settings API: OpenSearch/Elasticsearch cluster and index settings, the vector database's config.
- **Wire out (read):** indexing and search latency, queue rejections, merge pressure (the engine's stats API).
- **Wire in (write):** index refresh interval, merge throttling, shard counts and search thread pools through the settings API.
- **Restore:** settings recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** index workers (Distribution 37), embedding workers (Distribution 43), segment merge rate (Distribution 48), vector batch size (Distribution 60), shard count (Distribution 63), shard replication (Distribution 64), query route (Distribution 72), shard rebalance (Distribution 75), vector search k (Distribution 79), index refresh rate (Distribution 87), search concurrency (Distribution 213), search timeout (Distribution 214), index memory budget (Distribution 215), hot shard isolation (Distribution 216), search admission (Distribution 217), circuit breakers (Distribution 251).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

G.3.34 Container Resources (25 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the pod's own resource requests and limits (the Deployment template) and, where it runs, the VPA, Goldilocks or CruiseKube recommender.
- **Wire out (read):** each pod's CPU use (kubectl top), its request and limit, the node's allocatable CPU (Kubernetes API).
- **Wire in (write):** the running pod's CPU limit in place through pods/resize (no restart); the template is never changed, so no rollout.
- **Restore:** the operator's limit recorded in an annotation before the first write; every pod returned to it.
- **Run live?** live: omni_controller/muscles.py convey() (conveyance); KEDA and Goldilocks tables.
- **Its muscles, heaviest hitter first:** default limits (Compute 102), io latency target (Compute 109), cpuset (Compute 112), memory high (Compute 113), cpu weight (Compute 114), pids limit (Compute 118), memory limit (Compute 119), memory hard limit (Compute 121), goldilocks vpa request recommendation (Compute 122), runtime class (Compute 124), in place resize (Compute 134), cruisekube request rightsizing (Compute 138), cgroup io max (Compute 146), cpu limit (Compute 152), memory protection (Compute 153), swap limit (Compute 155), io weight (Compute 156), cpu request (Compute 159), ephemeral storage (Compute 160), hugepages (Compute 168), memory reclaim (Compute 178), memory request (Compute 184), cpu quota (Compute 321), namespace quota (Compute 387), freeze (Compute 388).

G.3.35 Linux Kernel & OS Control (20 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `cpu_host` (a CPU host whose clock and power can be set), reached through Linux cpufreq and RAPL. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the Linux kernel's own tunables: cgroup v2 files, /proc/sys/vm and net, the cpufreq and cpuidle governors, the I/O scheduler.
- **Wire out (read):** /sys/fs/cgroup, /proc/pressure, /proc/vmstat, /sys/block queue stats, the frequency files.
- **Wire in (write):** cgroup cpu.weight, cpu.max and memory.high; sysctl vm and net keys; scaling_max_freq, through sysfs and sysctl (root).
- **Restore:** every file snapshotted once and restored byte for byte.
- **Run live?** the CPU frequency path is written (tools/run_cpu_power.py); the other knobs are registered and queued, they need a real Linux machine.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Its muscles, heaviest hitter first:** irqbalance affinity (Compute 103), hugepage pool reserve (Compute 116), cgroup cpu weight (Compute 135), cgroup cpu quota (Compute 173), cgroup memory high (Compute 174), tcp buffer autotune (Compute 195), io scheduler depth (Compute 199), block nr requests (Compute 200), net rx coalesce (Compute 202), cfs scheduler latency (Compute 275), transparent hugepages (Compute 276), numa auto balancing (Compute 277), dirty ratio writeback (Compute 278), vm swappiness (Compute 279), zswap pool fraction (Compute 280), page cache reclaim (Compute 281), net qdisc codel target (Compute 282), cpufreq dvfs governor (Compute 415), ksm memory dedup (Compute 416), cpu cstate governor (Compute 417).

G.3.36 Telecom RAN & Edge Radio (12 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `ran` (a radio access network cell or site), reached through the RAN controller (O-RAN interfaces). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the RAN's near-real-time RIC and O-RAN interfaces (E2, O1).
- **Wire out (read):** PRB use, connected UEs, cell load, handover rates (the RIC's KPIs).
- **Wire in (write):** scheduler weights, slice budgets and traffic steering through the RIC's xApps; transmit power within the licence.
- **Restore:** recorded; restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** ran scheduler weight (Distribution 44), ran ue handover (Distribution 76), ran antenna tilt (Distribution 77), ran carrier enable (Distribution 84), ran cell sleep (Distribution 85), ran prb allocation (Distribution 91), ran du cu placement (Distribution 100), ran cell traffic steering (Distribution 105), ran connection admission (Distribution 267), ran slice resource budget (Distribution 268), ran tx power (Distribution 269), ran fronthaul budget (Distribution 270).

G.3.37 Host CPU & Memory (26 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `cpu_host` (a CPU host whose clock and power can be set), reached through Linux cpufreq and RAPL. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the Linux kernel's own governors: cpufreq (schedutil or the processor driver), RAPL, cpuidle, the memory manager.
- **Wire out (read):** /sys/devices/system/cpu/cpufreq (frequencies and governor), /sys/class/powercap intel-rapl energy counters, /proc/stat busy share, /proc/pressure.
- **Wire in (write):** scaling_max_freq per policy and the RAPL package power limit through sysfs (root); on Kubernetes through the Kubernetes Power Manager's PowerProfile or EAR's policy.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Restore:** the governor's files snapshotted once and restored byte for byte (tools/run_cpu_power.py --restore).
- **Run live?** written and tested on the modelled machine (tools/run_cpu_power.py, cpu-power.yml); GitHub's machines are virtual and cannot write the governor: the live run needs a real Linux machine.
- **Its muscles, heaviest hitter first:** swappiness reclaim (Compute 115), core packing (Compute 133), irq affinity (Compute 136), memory bandwidth (Compute 139), llc allocation (Compute 143), page reclaim rate (Compute 150), turbo boost (Compute 172), transparent hugepages (Compute 183), numa balance (Compute 185), core online offline (Compute 187), cpufreq min (Compute 333), cpufreq max (Compute 334), rapl package power (Compute 335), uncore frequency (Compute 336), energy perf preference (Compute 337), cpu idle policy (Compute 338), memory pressure gate (Compute 339), thermal throttle policy (Compute 340), host power profile (Compute 341), frequency governor (Compute 392), dram power limit (Compute 393), per pod cpu frequency range and c state access (Compute 401), uncore frequency per node (Compute 402), ear cpu frequency policy (Compute 407), ear global energy budget (Compute 408), k8s power manager core profile (Compute 409).

G.3.38 Media Streaming & CDN (14 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the streaming stack's transcoder pools, packager and CDN settings.
- **Wire out (read):** transcode queue, GPU clocks, buffer health, origin load (the stack's metrics).
- **Wire in (write):** worker pools, bitrate-ladder cap and cache TTLs through the stack's API; GPU clocks through nvidia-smi (family 9).
- **Restore:** recorded; restored.
- **Run live?** modelled; the GPU path is live (family 9).
- **Its muscles, heaviest hitter first:** drm license server pool (Compute 132), packager workers (Compute 151), origin shield cache size (Compute 191), transcoder worker pool (Compute 233), thumbnail sprite batch (Compute 248), abr bitrate ladder cap (Compute 288), player buffer target (Compute 289), edge cache ttl (Compute 290), segment duration target (Compute 291), encoder lookahead frames (Compute 292), live transcode gpu clocks (Compute 431), vod transcode batch power (Compute 432), cdn request coalescing (Compute 433), media ingest admission (Compute 434).

G.3.39 Blockchain & Ledger Nodes (10 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `cpu_host` (a CPU host whose clock and power can be set), reached through Linux cpufreq and RAPL. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Native controller:** the node's configuration (cache sizes, peer limits, mempool) and its host's power profile.
- **Wire out (read):** block relay latency, mempool size, peer counts, validation backlog (the node's RPC).
- **Wire in (write):** cache and pool sizes through the node's config and RPC; the host's power profile through family 8.
- **Restore:** recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** script validation threads (Compute 179), archive node storage tier (Compute 203), node db cache size (Compute 204), max peer connections (Compute 210), indexer batch workers (Compute 250), mempool max size (Compute 295), utxo cache flush interval (Compute 296), block relay admission (Compute 438), rpc work queue depth (Compute 439), validator host power profile (Compute 440).

G.3.40 Storage Block/File/Object (20 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `storage` (block, file or object storage), reached through the storage system's QoS and tiering API. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the storage system's QoS and tiering: Ceph (ceph osd pool set, QoS), a cloud volume's IOPS class, S3 lifecycle.
- **Wire out (read):** IOPS, throughput, latency and queue depth from the storage system's metrics.
- **Wire in (write):** volume IOPS and throughput limits, replica counts and tiering through the storage API or CSI VolumeAttributesClass.
- **Restore:** the volume's class and limits recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** lifecycle tiering (Distribution 97), erasure code profile (Distribution 99), throughput limit (Distribution 104), scrub schedule (Distribution 106), volume placement (Distribution 109), volume size (Distribution 111), cache allocation (Distribution 116), object replication (Distribution 118), storage tier (Distribution 119), backfill rate (Distribution 120), replica count (Distribution 128), recovery rate (Distribution 129), rebalance (Distribution 131), io scheduler (Distribution 132), snapshot trigger (Distribution 133), compaction pressure (Distribution 134), iops limit (Distribution 140), storage admission (Distribution 195), degraded storage gate (Distribution 196), disk power spin down (Distribution 250).

G.3.41 Skin: Perimeter & Admission (5 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `network` (network routing and switching), reached through the network controller (SDN, routing API). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Native controller:** the perimeter's own controls: the WAF, the DDoS shield, the TLS terminator.
- **Wire out (read):** request admission, inspection sampling, session cache hit rate (the perimeter's metrics).
- **Wire in (write):** token-bucket rates, sampling and session cache size through the perimeter's API; blocking rules never loosened.
- **Restore:** recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** tls session cache (Compute 192), rate limit token bucket (Compute 427), connection admission (Compute 428), waf inspection sampling (Compute 429), ddos shield admission (Compute 430).

G.3.42 Network Routing & Switching (19 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `network` (network routing and switching), reached through the network controller (SDN, routing API). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the network controller: the load balancer's weights, the SDN controller, the NIC's ethtool and tc settings.
- **Wire out (read):** link utilisation, drops, queue latency (SNMP, the controller's API, ethtool -S).
- **Wire in (write):** LB and route weights through the controller's API; rate limits and queue disciplines through tc; NIC queues through ethtool.
- **Restore:** every weight and setting recorded; restored with the same commands.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** bandwidth limit (Distribution 108), nic interrupt coalescing (Distribution 112), nic queue count (Distribution 113), route weight (Distribution 115), qos class (Distribution 117), nic ring size (Distribution 121), lb weight (Distribution 125), queue discipline (Distribution 126), congestion control (Distribution 135), path selection (Distribution 136), failover route (Distribution 137), ecmp weight (Distribution 138), rate limit (Distribution 182), connection limit (Distribution 183), nic rate limit (Distribution 184), egress budget (Distribution 185), ingress budget (Distribution 186), network isolation (Distribution 187), port link power (Distribution 249).

G.3.43 Content Delivery & Edge Cache (6 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `network` (network routing and switching), reached through the network controller (SDN, routing API). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the CDN's configuration API and the edge cache's settings.
- **Wire out (read):** hit ratio, origin load, TTLs (the CDN's metrics).
- **Wire in (write):** cache TTLs, origin-shield concurrency and prefetch through the CDN API.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

- **Restore:** recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** origin shield concurrency (Distribution 114), edge cache size (Distribution 122), cdn cache ttl (Distribution 171), prefetch aggressiveness (Distribution 172), tiered cache promotion (Distribution 271), edge pop admission (Distribution 272).

G.3.44 GPU Fabric & RDMA (18 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `fabric` (a high-speed fabric (RDMA, DPU, SmartNIC)), reached through the fabric manager's API. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the fabric manager and the collective library (NVIDIA Fabric Manager, NCCL settings, RDMA CM).
- **Wire out (read):** link and NVSwitch counters (nvidia-smi nvlink, DCGM), collective time per step from the training job.
- **Wire in (write):** NCCL environment and the job's rank placement at launch; RDMA QoS through the fabric manager's API.
- **Restore:** the launch settings recorded; the next job launched with the originals.
- **Run live?** modelled; written against NCCL and Fabric Manager documentation.
- **Its muscles, heaviest hitter first:** rdma bandwidth (Compute 205), nic affinity (Compute 207), congestion response (Compute 213), nvlink placement (Compute 215), nvswitch route (Compute 218), rail selection (Compute 219), collective protocol (Compute 220), rank placement (Compute 221), gpudirect policy (Compute 222), nic hca selection (Compute 224), collective algorithm (Compute 228), fabric failover (Compute 229), rdma route (Compute 230), collective chunk size (Compute 232), gpu fabric quarantine (Compute 348), collective concurrency (Compute 349), communication priority (Compute 350), fabric isolation (Compute 351).

G.3.45 DPU SmartNIC & Programmable IO (12 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `fabric` (a high-speed fabric (RDMA, DPU, SmartNIC)), reached through the fabric manager's API. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the DPU's own management (NVIDIA DOCA, the SmartNIC's SDK) and SR-IOV.
- **Wire out (read):** per-function rates, flow-steering hits, DPU CPU and memory (the DPU's counters).
- **Wire in (write):** rate limits, QoS groups and VF counts through the DPU management API.
- **Restore:** recorded; restored.
- **Run live?** modelled.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Its muscles, heaviest hitter first:** dpu sf tx rate (Compute 206), smartnic flow steering (Compute 208), dpu service placement (Compute 209), sriov vf count (Compute 216), smartnic offload enable (Compute 217), dpu pf tx rate (Compute 223), dpu vf tx rate (Compute 225), dpu bandwidth share (Compute 226), dpu qos group (Compute 227), dpu failover (Compute 231), dpu cpu budget (Compute 413), dpu memory budget (Compute 414).

G.3.46 Workflow, Logistics & Fulfillment (15 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `workflow` (a workflow or pipeline engine), reached through the workflow engine's concurrency settings. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the workflow engine (Temporal, Airflow, Camunda) and the fulfilment system's dispatch rules.
- **Wire out (read):** task queue depth, worker utilisation, SLA misses (the engine's metrics).
- **Wire in (write):** worker rates, concurrency and retry policies through the engine's API.
- **Restore:** recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** route replan (Distribution 141), compensation action (Distribution 142), shipment batch (Distribution 143), warehouse queue (Distribution 154), workflow worker rate (Distribution 159), inventory allocation (Distribution 160), fulfillment route (Distribution 161), carrier selection (Distribution 162), task queue rate (Distribution 163), sla escalation (Distribution 164), workflow admission (Distribution 244), workflow retry (Distribution 245), workflow backoff (Distribution 246), workflow timeout (Distribution 247), dispatch priority (Distribution 248).

G.3.47 AI Training (18 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `gpu_batch` (GPU training and batch work), reached through nvidia-smi, the job scheduler's pause and resume. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the training job's launcher and scheduler (Kubeflow, Ray Train, Slurm, torchrun).
- **Wire out (read):** step time, GPU utilisation, checkpoint cadence, stragglers (the job's metrics).
- **Wire in (write):** the job's worker count (elastic training), batch sizes and checkpoint interval through the launcher's API or the job spec.
- **Restore:** the job spec recorded; the next run launched from it.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** checkpoint trigger (Compute 234), straggler mitigation (Compute 235), training workers (Compute 239), data parallelism (Compute 240), gradient accumulation (Compute 242),

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

checkpoint interval (Compute 246), pipeline parallelism (Compute 252), expert parallelism (Compute 254), tensor parallelism (Compute 255), global batch size (Compute 256), elastic worker count (Compute 265), microbatch size (Compute 269), dataloader workers (Compute 270), training gang size (Compute 271), compute comm overlap (Compute 272), activation checkpointing (Compute 273), training preempt (Compute 359), training precision (Compute 360).

G.3.48 Data Analytics & ETL (15 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `batch` (batch and queued jobs), reached through the job queue (Kubernetes Jobs, Slurm, Spark). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** Spark's dynamic allocation and the SQL engine's slots (spark.dynamicAllocation, Flink's parallelism, warehouse slots).
- **Wire out (read):** executor count, task backlog, shuffle spill, stage times (the engine's metrics).
- **Wire in (write):** dynamic allocation min and max, parallelism and slots through the engine's config at submit or its REST API.
- **Restore:** the submit settings recorded; the next job launched from them.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** stage parallelism (Distribution 145), executor size (Distribution 146), shuffle bandwidth (Distribution 147), cache fraction (Distribution 149), shuffle partitions (Distribution 150), dynamic allocation max (Distribution 151), speculation policy (Distribution 152), batch interval (Distribution 153), dynamic allocation min (Distribution 155), query slots (Distribution 156), data locality wait (Distribution 158), etl concurrency (Distribution 218), spill threshold (Distribution 219), stream backpressure (Distribution 220), analytics admission (Distribution 221).

G.3.49 HPC & Distributed Compute (19 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `batch` (batch and queued jobs), reached through the job queue (Kubernetes Jobs, Slurm, Spark). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the batch scheduler: Slurm (scontrol, sacctmgr), PBS, LSF.
- **Wire out (read):** queue depth, node states, job wait times, power per node (sacct, sinfo, the power plugin).
- **Wire in (write):** partition limits, job priority and fair-share factors, node power-saving settings through scontrol and the scheduler config.
- **Restore:** the scheduler's settings recorded; restored with the same commands.
- **Run live?** modelled; EAR (family 8) is the live energy path on HPC.
- **Its muscles, heaviest hitter first:** rank mapping (Compute 236), backfill policy (Compute 238), job slots (Compute 241), job walltime (Compute 244), checkpoint restart (Compute 245), mpi ranks (Compute

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

247), node allocation (Compute 249), accelerator share (Compute 251), cpu gpu ratio (Compute 260), partition limits (Compute 263), memory per rank (Compute 274), job priority (Compute 361), job preemption (Compute 362), parallel io budget (Compute 363), collective budget (Compute 364), scratch budget (Compute 365), scheduler fair share (Compute 366), node power saving (Compute 397), cpu frequency per job (Compute 398).

G.3.50 Distributed Cluster Managers (15 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `batch` (batch and queued jobs), reached through the job queue (Kubernetes Jobs, Slurm, Spark). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the cluster manager's scheduler: YARN, Mesos, Nomad, Ray.
- **Wire out (read):** queue lengths, resource reservations, preemptions (the manager's API).
- **Wire in (write):** quotas, reservations and preemption settings through the manager's API.
- **Restore:** recorded once, restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** worker allocation (Compute 237), resource reservation (Compute 243), oversubscription (Compute 253), resource reclaim (Compute 257), gang schedule (Compute 261), binpack pressure (Compute 264), spread pressure (Compute 266), maintenance evacuation (Compute 267), task admission (Compute 367), task priority (Compute 368), cluster quota (Compute 369), task preemption (Compute 370), queue fairness (Compute 371), deadline pressure (Compute 372), scheduler retry (Compute 373).

G.3.51 Ports & Maritime Logistics (12 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `port` (a container terminal's cranes and vehicles taking moves), reached through the terminal operating system and fleet controllers. Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the terminal operating system and the equipment fleet controllers.
- **Wire out (read):** moves waiting, cranes active, gate queue, equipment charge (the TOS).
- **Wire in (write):** crane and vehicle allocation, gate rate and charging windows through the TOS.
- **Restore:** recorded; restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** rail mounted gantry dispatch (Distribution 165), quay crane allocation (Distribution 166), stacking height target (Distribution 167), horizontal transport fleet size (Distribution 168), yard crane fleet size (Distribution 169), shore power connection capacity (Distribution 170), berth window admission (Distribution 261), truck gate rate limit (Distribution 262), reefer plug power budget

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

(Distribution 263), container dwell priority (Distribution 264), vessel arrival pacing (Distribution 265), equipment charging window (Distribution 266).

G.3.52 Industrial PLC & Process Automation (18 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `process` (an industrial process loop), reached through the PLC or DCS (OPC UA, EtherNet/IP, PROFINET). Omni-Compass reads how far the process sits from its band.

- **Native controller:** the PLC or DCS loop (OPC UA, EtherNet/IP, PROFINET): the setpoint and the mode of each loop.
- **Wire out (read):** the process value, setpoint, output and alarm state of each loop (OPC UA reads).
- **Wire in (write):** the loop's setpoint within its safe band and its actuator range by OPC UA write; safety interlocks are never written.
- **Restore:** every setpoint read once and restored; a value outside the band is refused by the plug.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** valve position (Energy 34), furnace setpoint (Energy 35), pressure setpoint (Energy 36), temperature setpoint (Energy 37), mass flow setpoint (Energy 38), tank level target (Energy 39), plc cycle authority (Energy 153), machine cell admission (Energy 154), pump flow (Energy 155), compressor speed (Energy 156), heater power (Energy 157), conveyor rate (Energy 158), feed rate (Energy 159), purge vent action (Energy 160), controller mode (Energy 175), alarm limits (Energy 176), safety interlock trip (Energy 177), opc ua writes (Energy 178).

G.3.53 Cooling, Chillers & Thermodynamics (18 muscles)

Each is a data hall or building zone cooled by chillers, air handlers or fans; its class is `data_hall` (a data hall cooling plant), reached through the building management system (BACnet, Modbus) or its command line. Omni-Compass reads its temperature against its limit.

- **Native controller:** the building management system and the chiller plant's own supervisory controller (BACnet, Modbus).
- **Wire out (read):** supply and return temperatures, chiller load, fan and pump speeds, rack inlet temperatures (BACnet reads).
- **Wire in (write):** supply-air and chilled-water setpoints, fan and pump speeds within their safe bands by BACnet write; the plant's own staging keeps control.
- **Restore:** every setpoint read once and restored.
- **Run live?** modelled (the data-hall plant); the BACnet path is written.
- **Its muscles, heaviest hitter first:** supply air temperature (Energy 45), return air target (Energy 46), coolant supply temperature (Energy 47), coolant flow (Energy 48), pump speed (Energy 49), fan speed (Energy 50), chiller setpoint (Energy 51), cooling tower fan (Energy 52), cooling capacity (Energy 53), gpu thermal envelope (Energy 54), cpu thermal envelope (Energy 55), server fan speed (Energy 57),

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

economiser (Energy 58), chiller plant supervisory control rl with safety layer (Energy 65), compressor authority (Energy 166), rack thermal budget (Energy 167), thermal workload migrate (Energy 168), thermal load shed (Energy 169).

G.3.54 Building & Critical Environment HVAC (15 muscles)

Each is a data hall or building zone cooled by chillers, air handlers or fans; its class is `building` (a building zone), reached through the building management system. Omni-Compass reads its temperature against its limit.

- **Native controller:** the building management system (BACnet) and the AHU and zone controllers.
- **Wire out (read):** zone temperatures, airflows, duct static pressure, occupancy (BACnet reads).
- **Wire in (write):** zone setpoints, fan speeds and damper positions within their bands by BACnet write; the BMS's own sequences keep control.
- **Restore:** every setpoint read once and restored.
- **Run live?** modelled: CityLearn districts (results/live/V3_CITYLEARN.md); the BACnet path is written.
- **Its muscles, heaviest hitter first:** setpoint reset trim and respond (Energy 59), duct static pressure setpoint (Energy 60), optimal start stop (Energy 61), zone temperature target (Energy 145), zone airflow (Energy 146), ahu fan speed (Energy 147), damper position (Energy 148), economizer position (Energy 149), boiler setpoint (Energy 150), humidity target (Energy 151), thermal storage dispatch (Energy 152), heat pump mode (Energy 246), occupancy ventilation (Energy 247), building demand limit (Energy 248), hvac emergency mode (Energy 249).

G.3.55 Healthcare Critical Environments (13 muscles)

Each is a data hall or building zone cooled by chillers, air handlers or fans; its class is `hospital` (a hospital's critical rooms (operating rooms, isolation, pharmacy, imaging suites)), reached through the hospital's building management system (BACnet). Omni-Compass reads its temperature against its limit.

- **Native controller:** the hospital's building management system (BACnet) with its clinical limits.
- **Wire out (read):** room pressures, air changes, temperatures and humidity (BACnet reads).
- **Wire in (write):** setpoints within the clinical envelope by BACnet write; pressure cascades and alarms never loosened.
- **Restore:** every setpoint read once and restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** operating room air change setpoint (Energy 66), isolation room pressure target (Energy 67), patient room temperature setpoint (Energy 68), surgical suite humidity target (Energy 69), ahu supply air temperature (Energy 70), pharmacy cold room setpoint (Energy 71), sterile storage humidity setpoint (Energy 72), imaging suite cooling capacity (Energy 73), chiller plant staging (Energy 74), exhaust fan capacity (Energy 75), ward night setback mode (Energy 181), medical gas plant demand limit (Energy 182), emergency power load shed (Energy 183).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only. All patents, copyrights and trademarks filed in the USA.

G.3.56 Agriculture & Irrigation (14 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `irrigation` (pumps, pressure and climate on a farm or in a greenhouse), reached through the pump station controller, the pivot panel or the climate computer (Modbus, the vendor cloud). Omni-Compass reads how far the process sits from its band.

- **Native controller:** the pump station controller, pivot panel or climate computer (Modbus, the vendor cloud).
- **Wire out (read):** pressure, soil moisture, temperature, flow (the controller's registers).
- **Wire in (write):** pump speed and climate setpoints within their bands by Modbus write.
- **Restore:** registers read once and restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** mainline pressure setpoint (Energy 76), soil moisture target (Energy 77), pivot speed setpoint (Energy 78), greenhouse temperature setpoint (Energy 79), greenhouse co2 target (Energy 80), vent position setpoint (Energy 81), grain dryer temperature setpoint (Energy 82), cold storage temperature setpoint (Energy 83), milking vacuum level setpoint (Energy 84), well drawdown level target (Energy 85), irrigation pump speed (Energy 184), fertigation dose (Energy 185), barn ventilation rate (Energy 186), drip zone dispatch (Energy 187).

G.3.57 Oil & Gas Pipelines (14 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `pipeline` (a pipeline segment with its compressors, pumps and valves), reached through pipeline SCADA (DNP3, Modbus, OPC UA). Omni-Compass reads how far the process sits from its band.

- **Native controller:** pipeline SCADA (DNP3, Modbus, OPC UA).
- **Wire out (read):** pressures, flows, line pack, compressor states (SCADA reads).
- **Wire in (write):** pressure and flow setpoints and unit staging within the safe envelope; protection never written.
- **Restore:** every setpoint read once and restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** compressor discharge pressure setpoint (Energy 86), pump station suction pressure target (Energy 87), line pack target (Energy 88), pipeline flow setpoint (Energy 89), terminal tank level target (Energy 90), heater outlet temperature setpoint (Energy 91), valve position target (Energy 92), cathodic protection voltage (Energy 93), compressor unit staging (Energy 188), vfd pump speed (Energy 189), leak detection shutdown (Energy 190), batch interface dispatch (Energy 191), drag reducing agent dose (Energy 192), pressure protection priority (Energy 193).

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

G.3.58 Mining & Mineral Processing (14 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `mill` (a grinding, flotation or materials-handling circuit), reached through the plant DCS or PLC (OPC UA). Omni-Compass reads how far the process sits from its band.

- **Native controller:** the plant DCS or PLC (OPC UA).
- **Wire out (read):** mill load, speed, pressures, densities, power (OPC UA reads).
- **Wire in (write):** loop setpoints within their bands by OPC UA write; shutdowns never written.
- **Restore:** every setpoint read once and restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** sag mill load setpoint (Energy 94), mill speed target (Energy 95), crusher gap setpoint (Energy 96), cyclone feed pressure target (Energy 97), thickener underflow density target (Energy 98), conveyor speed setpoint (Energy 99), dewatering pump level target (Energy 100), stockpile level target (Energy 101), flotation aeration rate (Energy 194), reagent dose (Energy 195), ventilation on demand airflow (Energy 196), slurry pump speed (Energy 197), tailings discharge shutdown (Energy 198), ore blend dispatch (Energy 199).

G.3.59 District Heating & Cooling (13 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `district_heat` (a district heating or cooling network), reached through the network control system and substation controllers (Modbus, M-Bus). Omni-Compass reads how far the process sits from its band.

- **Native controller:** the network control system and substation controllers (Modbus, M-Bus).
- **Wire out (read):** supply and return temperatures, differential pressure, storage level (the controllers).
- **Wire in (write):** supply temperature and pressure setpoints, pump speed and staging within their bands.
- **Restore:** registers read once and restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** supply temperature setpoint (Energy 102), return temperature target (Energy 103), differential pressure setpoint (Energy 104), thermal storage level target (Energy 105), outdoor reset setpoint (Energy 106), cooling network supply temperature (Energy 107), cooling storage level target (Energy 108), network pump speed (Energy 200), heat pump staging (Energy 201), chp dispatch (Energy 202), peak boiler heater output (Energy 203), substation flow limit (Energy 204), peak demand shed (Energy 205).

G.3.60 Power Generation & Turbine Control (14 muscles)

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `turbine` (a generating unit's governor, boiler or excitation loop), reached through the plant DCS and governor (OPC UA, IEC 61850; modelled only). Omni-Compass reads how far the process sits from its band.

- **Native controller:** the plant DCS and the unit's governor (OPC UA, IEC 61850).
- **Wire out (read):** unit load, frequency, pressures, temperatures (the DCS).
- **Wire in (write):** load setpoints and ramp limits within the dispatch envelope; protection and rod positions never written.
- **Restore:** recorded; restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** turbine speed droop setpoint (Energy 109), unit load setpoint (Energy 110), boiler steam pressure setpoint (Energy 111), feedwater level target (Energy 112), excitation voltage setpoint (Energy 113), hydro gate position target (Energy 114), combustion air ratio setpoint (Energy 115), cooling water flow setpoint (Energy 116), inlet guide vane position (Energy 117), nuclear rod position target (Energy 118), agc participation limit (Energy 206), reserve dispatch priority (Energy 207), turbine ramp rate limit (Energy 208), emissions shutdown (Energy 209).

G.3.61 Renewable Generation & Inverter Control (13 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `inverter` (a plant of grid-support inverters or wind turbines), reached through the plant controller and inverter settings (SunSpec, IEC 61850, IEEE 1547). Omni-Compass reads how far the process sits from its band.

- **Native controller:** the plant controller and inverter settings (SunSpec, IEC 61850, IEEE 1547).
- **Wire out (read):** active and reactive power, voltage, curtailment state (SunSpec registers).
- **Wire in (write):** volt-var and volt-watt setpoints, curtailment and ramp limits by SunSpec write within the interconnection agreement.
- **Restore:** registers read once and restored.
- **Run live?** modelled: SimBench grids solved by pandapower (results/live/V3_PANDAPOWER.md); the register path is written.
- **Its muscles, heaviest hitter first:** inverter volt var setpoint (Energy 119), inverter volt watt setpoint (Energy 120), plant reactive power target (Energy 121), rotor speed setpoint (Energy 122), inverter frequency droop setpoint (Energy 123), string mppt voltage setpoint (Energy 124), active power curtailment (Energy 210), wind turbine yaw offset (Energy 211), pitch angle limit (Energy 212), ramp rate limit (Energy 213), tracker stow mode (Energy 214), noise mode schedule (Energy 215), ice detection shutdown (Energy 216).

All patents, copyrights and trademarks filed in the USA.

G.3.62 Pharmaceutical & Food Manufacturing (14 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `batch_reactor` (a GMP batch reactor, fermenter or food process), reached through the batch control system (ISA-88, OPC UA). Omni-Compass reads how far the process sits from its band.

- **Native controller:** the batch control system (ISA-88, OPC UA) with the validated recipe limits.
- **Wire out (read):** process values and phase states (OPC UA reads).
- **Wire in (write):** setpoints within the validated recipe band only; a value outside it is refused by the plug.
- **Restore:** every setpoint read once and restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** reactor temperature setpoint (Energy 125), agitator speed setpoint (Energy 126), fermenter dissolved oxygen target (Energy 127), ph setpoint (Energy 128), pasteurizer holding temperature setpoint (Energy 129), freezer tunnel temperature setpoint (Energy 130), cleanroom pressure cascade setpoint (Energy 131), lyophilizer shelf temperature setpoint (Energy 132), chromatography flow setpoint (Energy 133), oven zone temperature setpoint (Energy 134), cip cycle dispatch (Energy 217), steam sterilizer cycle priority (Energy 218), refrigerant compressor authority (Energy 219), batch hold quarantine (Energy 220).

G.3.63 Grid Transmission & Distribution (12 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `feeder_voltage` (a distribution feeder's voltage), reached through the distribution management system (IEC 61850, DNP3; modelled only). Omni-Compass reads how far the process sits from its band.

- **Native controller:** the distribution management system and the devices' own controllers (IEC 61850, DNP3): regulators, capacitor banks, inverters.
- **Wire out (read):** feeder voltages, loads, tap positions, inverter output (the DMS).
- **Wire in (write):** regulator and transformer taps, capacitor switching and inverter reactive power within the planning envelope; protection never written.
- **Restore:** every setting read once and restored.
- **Run live?** modelled: SimBench grids (results/live/V3_PANDAPOWER.md).
- **Its muscles, heaviest hitter first:** voltage regulator tap (Energy 135), transformer tap (Energy 136), feeder voltage target (Energy 137), frequency droop setpoint (Energy 138), capacitor bank switch (Energy 221), inverter real power (Energy 222), inverter reactive power (Energy 223), feeder load transfer (Energy 224), distribution storage dispatch (Energy 225), demand response dispatch (Energy 226), grid protection mode (Energy 227), grid restoration sequence (Energy 228).

All patents, copyrights and trademarks filed in the USA.

G.3.64 Semiconductor Fab & Precision Manufacturing (13 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `chamber` (a controlled chamber (clean room, kiln, reactor)), reached through the PLC or DCS. Omni-Compass reads how far the process sits from its band.

- **Native controller:** the fab's MES and each tool's controller (SECS/GEM).
- **Wire out (read):** tool queues, chamber states, process values (MES and GEM).
- **Wire in (write):** lot dispatch and tool admission through the MES; chamber recipes and parameters never written outside the qualified window.
- **Restore:** recorded; restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** chamber temperature (Energy 139), chamber pressure (Energy 140), run to run control (Energy 179), idle sleep mode (Energy 180), tool job dispatch (Energy 229), wafer route (Energy 230), chamber recipe selection (Energy 231), gas flow (Energy 232), rf power (Energy 233), vacuum pump speed (Energy 234), robot transfer rate (Energy 235), lot priority (Energy 236), tool quarantine (Energy 237).

G.3.65 Water Wastewater & Pumping (12 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `water` (a water or pumping process), reached through the SCADA system (Modbus, DNP3). Omni-Compass reads how far the process sits from its band.

- **Native controller:** the utility's SCADA (Modbus, DNP3) and the pump station controllers.
- **Wire out (read):** levels, pressures, flows, aeration and dosing (SCADA reads).
- **Wire in (write):** pump speeds, level and pressure targets, aeration and dosing within their bands by SCADA write; emergency shutdowns never written.
- **Restore:** every setpoint read once and restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** valve position water (Energy 141), reservoir level target (Energy 142), line pressure target (Energy 143), flow target water (Energy 144), pump speed water (Energy 238), aeration rate (Energy 239), chemical dose rate (Energy 240), filtration backwash (Energy 241), lift station dispatch (Energy 242), leak isolation (Energy 243), water demand shed (Energy 244), water emergency shutdown (Energy 245).

G.3.66 Gut: Data-plane Intake & Waste (8 muscles)

Each is a regulated process: a temperature, pressure, flow, level, voltage or composition held at a setpoint; its class is `process` (an industrial process loop), reached through the PLC or DCS (OPC UA, EtherNet/IP, PROFINET). Omni-Compass reads how far the process sits from its band.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Native controller:** the data plane's own intake pacing and compaction settings (the ingress, the queue, the store's compactor).
- **Wire out (read):** intake rate, backpressure, compaction debt, dead-letter depth (the components' metrics).
- **Wire in (write):** pacing, drain rates and compaction budgets through each component's settings API.
- **Restore:** recorded; restored.
- **Run live?** modelled.
- **Its muscles, heaviest hitter first:** dead letter retry cap (Compute 285), ttl eviction waste (Compute 286), retry budget window (Compute 287), ingress intake pacing (Compute 422), gc compaction pacing (Compute 423), backpressure threshold (Compute 424), queue drain rate (Compute 425), compaction debt drain (Compute 426).

G.3.67 Work Admission & Demand Shaping (19 muscles)

Each is a pool of servers, pods, GPUs, links or disks serving a stream of requests or jobs; its class is `server` (an application service on servers or pods), reached through the Kubernetes API (HPA target and floor, pod resize). Omni-Compass reads how far its queue and its load sit toward the service line (queue or lateness, and load above half).

- **Native controller:** the service's own admission layer: its API gateway, queue or admission controller (Envoy, NGINX, Kong, a job queue's concurrency setting).
- **Wire out (read):** queue depth, requests in flight and the response-time line from the gateway's or queue's metrics (Prometheus, the admin API).
- **Wire in (write):** the gateway's or queue's concurrency and rate settings (the limit named by the muscle) through its admin API or its config object.
- **Restore:** snapshot of each limit once before the first write; every limit restored from it.
- **Run live?** at its limit on native: read and left native in every run (nothing is paced or turned away); the wire is read-only.
- **Its muscles, heaviest hitter first:** api concurrency (Compute 299), queue concurrency (Compute 300), queue backpressure (Compute 301), job admission (Compute 302), batch admission (Compute 303), inference admission (Compute 304), load shed (Compute 305), priority gate (Compute 306), tenant admission (Compute 307), burst limit (Compute 308), deadline admission (Compute 309), work budget (Compute 310), request queue limit (Compute 311), retry admission (Compute 312), background work gate (Compute 313), maintenance work gate (Compute 314), request concurrency limit (Compute 399), adaptive concurrency limit (Compute 404), priority request queue under limit (Compute 405).

G.3.68 Spacecraft & Flight Software (14 muscles)

Each is a motor-driven axis: a robot joint, a flight-control surface, a reaction wheel, a traction motor; its class is `reaction_wheel` (a spacecraft reaction wheel), reached through the attitude controller (modelled only). Omni-Compass reads its tracking error and its load.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Native controller:** the flight software's command and mode tables (cFS, F Prime).
- **Wire out (read):** attitude error, wheel speeds, power and thermal state from telemetry.
- **Wire in (write):** payload duty cycle, communication allocation and wheel allocation through commands; safe modes never commanded.
- **Restore:** the command table recorded; restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** space command admission (Physics 73), flight task schedule (Physics 74), space mode transition (Physics 75), payload duty cycle (Physics 76), communication allocation (Physics 77), space power budget (Physics 78), space thermal command (Physics 79), attitude command envelope (Physics 80), reaction wheel allocation (Physics 81), rcs authority (Physics 82), safe mode transition (Physics 83), watchdog recovery (Physics 84), instrument activation (Physics 85), fault isolation (Physics 86).

G.3.69 Rail Traction & Train Control (14 muscles)

Each is a motor-driven axis: a robot joint, a flight-control surface, a reaction wheel, a traction motor; its class is `rail_traction` (a train's traction and auxiliary systems), reached through the train control and management system and ATO (modelled only). Omni-Compass reads its tracking error and its load.

- **Native controller:** the train control and management system and ATO.
- **Wire out (read):** speed, traction effort, timetable margin, auxiliary power (TCMS telemetry).
- **Wire in (write):** traction and coasting targets within the ATO's envelope.
- **Restore:** recorded; restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** traction effort limit (Physics 92), regenerative braking share (Physics 93), coasting speed target (Physics 94), dwell time schedule (Physics 95), hvac duty cycle (Physics 96), train auxiliary power budget (Physics 97), platform approach speed (Physics 98), acceleration rate setpoint (Physics 99), wheel slip protection mode (Physics 100), traction motor thermal derate (Physics 101), catenary voltage limit (Physics 102), timetable recovery margin (Physics 103), headway target (Physics 104), door release hold (Physics 105).

G.3.70 Elevators & Vertical Transport (12 muscles)

Each is a motor-driven axis: a robot joint, a flight-control surface, a reaction wheel, a traction motor; its class is `elevator_hoist` (an elevator or escalator drive and its group control), reached through the lift controller and destination dispatch (modelled only). Omni-Compass reads its tracking error and its load.

- **Native controller:** the lift controller and destination dispatch.
- **Wire out (read):** calls waiting, car positions, drive temperature (the controller).
- **Wire in (write):** speed and dispatch modes within the manufacturer's limits; safety modes never written.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

- **Restore:** recorded; restored.
- **Run live?** modelled only.
- **Its muscles, heaviest hitter first:** hoist speed target (Physics 113), acceleration limit (Physics 114), regen drive mode (Physics 115), standby power mode (Physics 116), destination dispatch schedule (Physics 117), car parking mode (Physics 118), door dwell hold (Physics 119), escalator speed target (Physics 120), group capacity mode (Physics 121), motor thermal derate (Physics 122), brake test schedule (Physics 123), fire recall mode (Physics 124).

APPENDIX

Appendix H. Source of the Engine

The engine that stands, omni-v26, is the 65 files named in `OMNI_V26.json` (digest 75d3c22eed4473b9): 60 Python files and 5 tables. The Python files are printed here in full from the repository, in the fingerprint's order, so that the book and the code can be read side by side and nothing in the mechanism is withheld from the owner: the Kubernetes governor, its muscles, the replica room, the quota budget and the two card governors (`omni_controller/`); the engine core, the compass law, the compass, the verdict, the conveyance law, the plug adapter, the nervous system, the master switch and the rest of the library (`omnicompass/`); the modelled plants, the harness, the presets, the max's arm and the card's model (`realms/`); and the three runners the fingerprint covers (`tools/`). The tables are the muscle catalogs: `realms/catalog_v5.csv` (the 1,107 muscles, printed muscle by muscle in the Muscles appendix with every card of `realms/muscle_cards_v5.csv`) and the earlier catalogs kept for their results (`realms/catalog.csv`, `realms/catalog_v1.csv`, `realms/wave4_families.csv`). `python3 tools/omni_version.py` hashes every one of the 65 and prints omni-v26 when none has changed; `verify.py` fails if a byte of them differs from the fingerprint.

```
  observe   read the cluster every interval, run the fleet-mode govern
    ↪ or in OBSERVE, log every decision; no writes (default)
  target    additionally patch each HPA's CPU averageUtilization to rh
    ↪ o* (bounded, rate-limited); the Cluster Autoscaler and
            all node management remain unchanged
  nodepool  additionally size one node pool to the governor's recommen

    ↪ dation through --node-scale-cmd, a command template
            such as "aws autoscaling set-desired-capacity --auto-scali
    ↪ ng-group-name POOL --desired-capacity {n}"; the
            Cluster Autoscaler must not manage that pool
Laws (--law)
  governor  (default) the engine's allocation law sets the HPA target

    ↪ (rho*) and the closure law or the governor sizes the pool
  compass      the compass law (omnicompass/compass_law.py) holds the
    ↪ service in its band, read as the GPU compass reads it: the mean
            response time of the latency window between the bare servi
    ↪ ce time (a tenth of --slo-ms) and --slo-ms. At the
            max (--dial max, the default) the balance point stands at

    ↪ --compass-center (0.3: well inside the line, so every
            rush finds its pods already there) and no machine the clus
    ↪ ter had on its own is ever given back; at the
            tune-down (--dial save) it is held at the v5 edge (omnicom
    ↪ pass/edge.py: the balance point moves with the
            service's own risk, 1 - (climb x reaction + 3.09 x wobble)

    ↪ , never below 0.4 unless a breach while machines were
            given back has taught it otherwise) and the verdict below
    ↪ gives machines back; p95 at or past the SLO, a blind
            sense or pods waiting for a place read as past the wall. I
    ↪ ts push and pull move two levers: each HPA's CPU target inside i
    ↪ ts cover (from 60% of the

            operator's target up to the operator's own, never tighter
    ↪ than native, so it only ever adds pods and gives them
            back) and the node pool (one machine back only while the f
    ↪ orce is clearly down, the position below the center
            and the nervous system's release gate open; past the 0.95
    ↪ wall, one machine up at once). The verdict
```

All patents, copyrights and trademarks filed in the USA.

```
            (omnicompass/verdict.py, stepwise) decides how many machin
    ↪ es may be given back at all: while the service is
            calm, one more machine is given back on trial and the resp
    ↪ onse time of the requests served without it is set
            against the requests served just before and against the cl
    ↪ uster as it ran on its own at the start; at most

            --allow slower and that machine stays given back, slower t
    ↪ han that and it is taken back and not tried again
            for --verdict-recheck decisions. Where no machine passes,
    ↪ the pool stays as the cluster runs it alone. The
            six-state engine still runs every decision: it grants the
    ↪ authority, feeds the release gate and the compass,

            and is audited
Safety
  every node action passes through the shield (bounds, step limit); th
    ↪ e recommendation never falls below what the CPU
  requests of running and pending pods, or current usage, need, and ca
    ↪ pacity required by that floor is added in one step

  (the step limit applies only to the governor's own adjustments); --d
    ↪ ry-run logs intended writes without executing them; creating the
    ↪  kill file (or
  setting OMNI_KILL=1) restores every HPA target this controller chang
    ↪ ed, runs --node-restore-cmd if given, and returns to
  observe; every decision and action

  is appended to the audit log.
Requires kubectl on PATH with access to the cluster (metrics-server fo
    ↪ r kubectl top).

"""Omni-Compass on one GPU through two wires: the compass law (omnicom
    ↪ pass/compass_law.py) on a real card.

The card keeps its own control: NVIDIA's firmware still boosts and sti
    ↪ ll protects the chip. Omni holds two settings the
card already accepts, and nothing else:
  up wire    the clock ceiling: how high boost may climb (nvidia-smi -
    ↪ lgc MIN,MAX; -rgc resets it)
  down wire  the power limit: the lid above what that ceiling draws (n
```

```
    ↪ vidia-smi -pl W)

Every decision (--interval seconds):
  read      nvidia-smi: power.draw, temperature, utilization, power.li
    ↪ mit, clocks.sm; the workload's response times
  position  the service as one place in its compass, 0 calm to 1 the l

    ↪ ine: response time only (the mean over the last
            --latency-window-s, between a tenth of the line, the bare
    ↪ service time, and the line; the 95th percentile at
            or past the line, or a failed request, is past the wall).
    ↪ A card that is busy is doing its work; being busy
            is not a breach and is not read as one

  native    what the card does on its own, learned from its own meter
    ↪ before the compass may lower anything: while the
            ceiling is at the top and the card is busy, its clock and
    ↪ its draw (the clock its own power limit holds it
            at, and what that costs). Until --learn-samples busy readi
    ↪ ngs are in, the ceiling stays at the top

  race      while the card is saturated (utilization at or over --race
    ↪ -util: work is waiting), the ceiling goes to the
            top and the lid to the start limit, so a burst is served a
    ↪ t full speed; the compass paces only the slack
  force     the compass: pull to the center, push against what is risi
    ↪ ng, tanh-bounded; past the 0.95 wall: fail up

  verdict   how far the ceiling may go (omnicompass/verdict.py): while
    ↪  the service is calm, a paired trial: the ceiling
            at the top until --verdict-samples requests are measured,
    ↪ then one 15 MHz step past the deepest step
            already allowed until as many again are measured; the card
    ↪ 's own time on each request (the workload's

            service_ms, the wait in the queue left out) is compared: a
    ↪ t most --allow slower and the step is allowed,
            slower than that and it is refused and not tried again for
    ↪  --verdict-recheck decisions. Where no step
            passes, the ceiling stays at the top: the card runs as it
    ↪ does alone
```

```
  law       down gain 0.0125, the compass's center at the v5 edge (omn
    ↪ icompass/edge.py: 1 - (climb x reaction + 3.09 x
            wobble) of the card's own response-time position, never be
    ↪ low 0.4 unless a line crossed while the ceiling was
            held under the top has taught it otherwise; the wall moves
    ↪  out with the reaction part), the speed floor at the

            card's own busy clock (amendment 8)
  steady    while the card is saturated against its own power limit (w
    ↪ ork waiting and the draw at the limit), the
            firmware boosts a step, hits the limit and is knocked back
    ↪ : a sawtooth. The ceiling is then held at the
            card's own busy clock under that limit (what the sawtooth

    ↪ averages to), so the same watts serve the work
            without the knock-backs (amendment 9). Only under an opera
    ↪ tor's cap (the start limit under the card's
            factory limit, amendment 12): on the card's own limit the
    ↪ firmware's boost is left to serve the burst. It
            never holds under that clock, and blind always fails up

  write     up wire: the ceiling moves by the force (fast up, gently d
    ↪ own), inside its cover: from the card's own busy
            clock (never slower than native while there is work) to th
    ↪ e top; down wire: the lid at the card's own busy
            draw plus --lid-headroom, never under it and never over th
    ↪ e start limit, inside the declared envelope;

            fail up: ceiling to the top and the lid to the start limit
    ↪  at once
  guards    blind (meters unreadable, response times stale): fail up;
    ↪ heat (the card reports a thermal or hardware
            slowdown): never tighten; one writer: a power limit neithe
    ↪ r mine nor the start means another writer, so

            observe only from then on and exit 5; read-back: every wri
    ↪ te is read back
  restore   on exit, kill file or SIGTERM: clocks reset (-rgc) and the
    ↪  power limit back to the start, read back

The audit (--audit) carries the same records the bench reads from the
```

529 lines.

```
"""Omni-Compass on one GPU box, no Kubernetes: the engine reads each G
    ↪ PU's own meter and may lower its power limit.

Every decision (--interval seconds), for each GPU in --gpus:
  sense     nvidia-smi: power.draw, temperature.gpu, utilization.gpu,
    ↪ power.limit (the device's own readings)
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
          the workload's response-time file (--latency-file, elapsed
  ↪ _seconds,latency_ms,ok) if given
engine    the Omni-Compass governor, throughput law (omnicompass/ada
  ↪ pter.py): load = utilization, power stress =
          draw / the limit found at start, heat = temperature / --te
  ↪ mp-limit, queue = response-time pressure.

          Its directive power_cap is the share of the start limit th
  ↪ e GPU may draw.
shield    limit = max(cap x start limit, draw x (1 + --headroom), --
  ↪ min-share x start limit, the device's minimum
          limit), never above the start limit; whole watts; a change
  ↪  under --min-change-w is not written.

          --min-share bounds the slowdown: a card held at that share
  ↪  of its limit runs a burst only a little slower.
busy gate utilization (smoothed over decisions) at or above --util-g
  ↪ ate: the start limit. A busy card is the
          bottleneck; slowing it grows the queue faster than it save
  ↪ s energy. The cap returns once utilization is

          back under the gate less --util-band.
reflexes  a blind sense (nvidia-smi unreadable, or the response-time
  ↪  file stale or empty): the start limit, at once
          a response-time breach (p95 > --slo-ms), and for --slo-cle
  ↪ ar decisions after it: the start limit, at once
read-back no new write until the last one is read back from the devi

  ↪ ce (power.limit within 1 W of what I wrote)
enforced  the card obeys enforced.power.limit, which another authori
  ↪ ty (a lower board or system limit) can hold under
          the limit I request. The engine senses the enforced limit;
  ↪  each write is read back at once (requested,
          return code, power.limit, enforced limit, delay), and enfo

  ↪ rced under requested is recorded as an override.
          A driver without enforced.power.limit: power.limit is used
  ↪  and the snapshot says so.
speed lock (--baseline-file, from tools/gpu_baseline.py on a run wit
  ↪ hout Omni): the limit is set by response time
          alone. Over the last --lock-window-s of the response-time
```

All patents, copyrights and trademarks filed in the USA.

```
  ↪ file, the mean, 95th and 99th percentile are each
         divided by the baseline's at the same arrival rate; the wo
  ↪ rst of the three is the speed ratio. The line is
         1 - --speed-gain (0.99: at least 1% faster than without Om
  ↪ ni). Above the line: the start limit, at once.
         Under the line less --lock-margin: lower by --lock-step x

  ↪ start, times the slack in margins (up to
         --lock-boost), at most once per --lock-hold-s (the window
  ↪ must see the step before the next). Between: held. Never under -
  ↪ -lock-floor x start.
         Speed won elsewhere (CPU conveyed to the serving pods, sho
  ↪ rter queues) shows as a ratio under the line,

         and the lock spends it on watts; with nothing won elsewher
  ↪ e it holds the start limit.
one writer the limit must be what I last wrote (or the start limit).
  ↪  Any other value means another writer: I stop
         writing for the rest of the run (observe only), record "fo
  ↪ reign_writer", leave its limit alone on kill

         (restoring would fight it), and exit 5 so the bench marks
  ↪ the run invalid. Two controllers on one limit is
         how production is lost.
heat     the device reporting a thermal or hardware slowdown (clock
  ↪ -limit reasons 0x8, 0x20, 0x40, 0x80): never
         tighten; the limit may only stay or rise (fail up).

envelope  every decision records every rule that held the engine's r
  ↪ equest back ("blocked_by") and the one that
         decided ("decided_by": engine, a floor, the busy gate, a r
  ↪ eflex, heat, or the speed lock), so a limit that
         did not move names its cause, and a result is credited to
  ↪ the rule that produced it.

envelope  --floor-w, the buyer's declared lowest watts (the confirma
  ↪ tion run requires it, scripts/gpu_paired.sh
floor     ENVELOPE): the limit is never set under it. The highest wa
  ↪ tts are the limit read at start.
outer     when the card's own controller (board, BMC or system polic
  ↪ y) already holds enforced.power.limit under the
```

All patents, copyrights and trademarks filed in the USA.

```
  holds     limit I set, a lower write that stays above that enforced
    ↪ value would change nothing the card does: it is
            not written ("outer_controller_holds"). Only a write that
    ↪ would actually bind, or a return upward, goes out.
Modes
  watch     everything above is computed and audited; nothing is writt
    ↪ en (the control arm)
  cap       the limit is written with nvidia-smi -i <gpu> -pl <W>. Ref
    ↪ used at start unless every GPU reports
            power.management Enabled. A write the device refuses (nonz
    ↪ ero return) ends the run: recorded, the start
            limit restored, exit 4, and the bench marks the arm invali
    ↪ d. No clock locks are ever written.
Kill switch
  the kill file (or SIGTERM) restores every GPU to the limit read at s
    ↪ tart, reads it back, and exits.
  The start limits are recorded first in the audit ("snapshot": power.
    ↪ limit, enforced.power.limit, default, min,
  max, persistence mode, power management, per GPU).

"""Live muscles for the Kubernetes controller beyond HPA and nodes.

Each muscle pulls (afferent) and pushes (efferent) through kubectl, re
    ↪ cords what it changed so the reset can hand
the muscle back, and tags every write with its muscle name in the audi
    ↪ t log.

  power_cap   push: at the max (the default dial) the cap is never set
    ↪  under native: each machine's idle CPU is conveyed
              to the capped deployments' running pods (convey: one cli
    ↪ ck under the machine, its last 5% never handed out,
              never under the operator's limit), and the frequency cei
    ↪ ling and the GPU limit stay at their top. The
              tune-down (--dial save): CPU limit of each running pod =
    ↪  base limit x the governor's power cap, never under
              the pod's own request nor its use plus headroom (nothing
    ↪  fixed), resized in place (no restart; Linux CFS
              quota throttles the containers for real); pull: power fr
    ↪ om --power-cmd
  heat        pull: thermal state from the harness heat law driven by
    ↪ live power stress (modelled: kind has no thermometer)
  security    pull: ConfigMap key "hold" == "true" means a security ho
    ↪ ld; the shield then blocks every expansion
  rollout     push: pause a deployment's rollout while the governor do
    ↪ es not permit change; resume it when it does;
              undo a rollout that has exceeded its progress deadline w
    ↪ hen the governor authorises rollback

        """Energy to where the work is (omnicompass/conveyance.py, on
    ↪ one machine's CPU).

        A serving pod's CPU limit is a quota: a request that needs mor
    ↪ e CPU than one quota period allows waits for the
        next period, while the machine it runs on sits idle. That wait
    ↪  is energy withheld from the work, not saved: the
        request uses the same CPU-seconds either way. So each machine'
    ↪ s idle CPU is conveyed to the serving pods on it:

            c_i = min( max(L_i, (0.95 A_j - Q_j) / |P_j|), 0.95 A_j )
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    A_j the machine's allocatable CPU, Q_j what every other pod on
↪  it may use (its own limit, or its request where it
    has no limit: omni-v13; the requests alone before), P_j the se
↪ rving pods on it, L_i the operator's own limit. The
    machine's last five percent is never handed out (the living ba
↪ nd), a pod never gets

    less than its operator gave it, and the requests (what the sch
↪ eduler and the autoscaler read) are untouched.
    Resized in place through pods/resize: no pod restarts. No expa
↪ nsion during a security hold. The reset
    returns every pod to L_i.

    On kind every node is a container on one machine and reports t
↪ hat machine's whole CPU as its own, so the limits
    the nodes hand out sum to more than the machine: a ceiling, no
↪ t a use, and the kernel's fair scheduler arbitrates
    when the serving pods ask for more than the machine, as it doe
↪ s for native's pods. v7 adds one guard, the same

    as the replica room's (capacity.py): on such a shared host no
↪ limit is raised while the machine's measured busy
    share is at or over 75% or cannot be read; limits already give
↪ n stay, and lowering is never held back. Each hold
    is written to the audit ("convey": "held"). omni-v13 adds the
↪ hand-back: while another workload on the shared

    host has room of its own (a pod, not one of the serving pods,
↪ whose limit is above its request) and the host is
    at its top (busy at or over 75%), there is no idle CPU to conv
↪ ey, so every limit given goes back to the
    operator's; it is conveyed again only once the host's busy sha
↪ re is under 70% (the band's 5% cushion below the

    top), so the hand-back and the raise never chase each other. O
↪ n KubeRay's rig the limits given in the queue's
    first half minute stayed through the saturated queue: the batc
↪ h pods hashed 7.6% slower, the queue finished
    0.7% later and the web served no faster (20 October, docs/OMNI
↪ _V13.md). A host with no such workload keeps the
```

All patents, copyrights and trademarks filed in the USA.

```
    v7 rule: what the serving pods use there at the top is the hos
↪ t's own idle, and no other muscle's room.
    Two other designs were tried in the model gate (tools/model_ga
↪ te.py,
    docs/OMNI_V7.md) and refused by it: the host's CPU counted onc
↪ e and shared by every serving pod (at the v6 KEDA

    runs' nine replicas, 3,500m / 9 is under the operator's 500m,
↪ so nothing is ever conveyed and the +64% work and
    -53% response time of conveyance are lost whole), and a hold w
↪ hile a pod starts on the host (a start wait 1%
    shorter for a LOSS on work and speed). The slower pod start of
↪  the v6 KEDA runs (+12.5% mean, EVEN on the

    three-run rule) is the busier host serving more requests: the
↪ price of the work, not a fault to hold against.
    The namespace's CPU quota, where the governor's role can read
↪ it, bounds every raise (omni_controller/quota.py);
    where it cannot be read, no budget is known and the raise proc
↪ eeds as on v6, Kubernetes' own admission the

    authority: the first v7 trial read an unreadable quota as zero
↪  and conveyed nothing (docs/OMNI_V7.md, section 1).

    Conveyance is on by default. It moves no work: the same reques
↪ ts run with less waiting. (The +26% CPU seen on
    kind is more requests served, because that load is closed-loop

↪ , not waste.) Optionally, --convey-on (a share
    of --slo-ms) engages it only once the 95th-percentile response
↪  time reaches convey-on x SLO and releases it
    below convey-off x SLO, returning every serving pod to L_i; a
↪ blind latency sense engages it (service first)."""

"""How many units, how many machines, and how much processor each unit
    ↪  may use.

Yardstick   the Kubernetes Horizontal Pod Autoscaler's published rule,
    ↪  written here from its documentation as the
            measure Omni is read against (it is not Kubernetes' code):
    ↪  every 15 s the units become
            ceil(units × busy ÷ target), busy being the processor the
    ↪ units used over their requests (a pod never uses

            more than its limit, here its request, so busy is read cap
    ↪ ped at the request), target 50%; no move inside a
            10% tolerance; a rise at most to max(2 × units, units + 4)
    ↪  at once; a fall only to the highest count it
            recommended over the last 300 s.

OmniBrain   Omni-Compass's own, the max riding the edge of the organis
    ↪ m:
            the reflex    work waiting in line at the front (every han
    ↪ d busy) adds units now, one for each request
                          waiting, up to the step; a request in line i
    ↪ s the organism's own signal, read in the beat;

            the compass   the compass law (omnicompass/compass_law.py)
    ↪  on the service's 95th percentile response time in
                          the band from 0 to the service's line: a for
    ↪ ce up adds units at once in proportion to it (past
                          the wall, the most it may add); a force down
    ↪  gives back one unit, only after it has held down

                          for three beats with no request waiting;
            the twin      the yardstick's rule computed on the same re
    ↪ adings, what Kubernetes would hold for this work:
                          Omni holds at least that, less only the dept
    ↪ h the verdict has allowed (omnicompass/verdict.py,
                          the engine's own trigger): one unit fewer th
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    ↪ an the twin is tried on the service itself and kept
                          only where the response time measured under
    ↪ it reads no LOSS against the count before, within
                          the 2% allowance; a trial walks to its step
    ↪ one unit a beat, stands there while it measures,
                          and is abandoned the moment work waits or th

    ↪ e wall is reached. Work waiting in line hands one
                          allowed step back (the immune reaction: harm
    ↪  seen, the knob steps toward native).

conveyance  the processor each unit may use (its CPU wall), the engine
    ↪ 's own rule (omni_controller/muscles.py, omni-v7

            and omni-v13): the room under 75% of its machine, less the
    ↪  other workloads' units on it counted by their
            limits, shared equally among the service's units there, ne
    ↪ ver under a unit's request and never over the
            machine; no new raise while the machine is 75% busy or its
    ↪  busy share is unread; at the top beside another

            workload's room every limit goes back to the request, conv
    ↪ eyed again under 70%. A unit whose wall stands
            above its request answers at its machine's own speed inste
    ↪ ad of its paper quota's: faster, with no unit and
            no machine added. Kubernetes' autoscaler never moves a lim
    ↪ it; it adds pods.

machines    how many machines the units need: their requests, plus roo
    ↪ m for the most units the brain may add at once,
            so a unit never waits for a machine; never fewer than the
    ↪ floor (two).

```
A group is omni/<machine> for a machine and omni/<machine>/<unit> for
    ↪ a unit. A machine's CPU quota caps everything in
it; a unit's quota caps the unit; the kernel's own counter gives the p
    ↪ rocessor time each one used. Version 2 (cgroup.controllers
at the root, the default on modern kernels and on GitHub's runners): c
    ↪ pu.max, memory.max, cpu.stat, and the cpu and memory

controllers handed down to each level through cgroup.subtree_control;
    ↪ processes live only in the leaves (the units). Version 1
(the cpu, cpuacct and memory hierarchies mounted apart): cpu.cfs_quota
    ↪ _us, memory.limit_in_bytes, cpuacct.usage. Where the
groups cannot be written, nothing is walled and `Walls.make` says so (
    ↪ the caller records it)."""

"""The control plane: one process that decides; the hands on the machi
    ↪ nes and the front do the rest.

The ledger is what is wanted (units per service, the state of every ma
    ↪ chine, batch tasks done) and what was placed
(every unit: its machine, its port). Every change to it is a line in t
    ↪ he journal before it is acted on, so a control
plane that is killed and started again replays the journal and finds t
    ↪ he same ledger; the units it finds running on the

machines are taken back as they are, none started again. Every second
    ↪ it:

  1. asks every machine's hand for its status; a machine silent three
    ↪ times running is down, and its units are placed
     again elsewhere; a unit a machine runs that the ledger does not k
    ↪ now is stopped;
  2. stops the units retiring once their drain is over (out of the rou
    ↪ tes first, so no request is lost);
  3. on the brain's beat, decides the units of each service (brain.py:
    ↪  the reflex on work in line, the compass law on the
     95th percentile, the yardstick twin less the depth the verdict ha
    ↪ s allowed on the service's own response times) and,
     for Omni, the machines (wake before any unit would wait, park one
    ↪  at a time after the load has held low for three
     beats, its units moved first) and each unit's CPU wall (the engin
    ↪ e's conveyance: the room its machine can still
     give under 75%, journaled, written to the hand and read back);
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
  4. places the units the ledger lacks (the scheduler's room rule), re
    ↪ tires the extra ones, and lets batch tasks into
     the room the services leave (a task yields its room the moment a
    ↪ service needs it);
  5. writes the routes for the front (only ready units) and one line o
    ↪ f the timeline.

The kill switch is a file: while it exists the brain is off and the de
    ↪ clared state is held (the declared units, every
machine on, every wall at its request). Every decision is a line in th
    ↪ e audit with its reason.

"""One address for a service: its own process, so the service answers
    ↪ while the control plane is down.

Every request joins one line; each ready unit has one hand (a thread w
    ↪ ith one kept-open connection) that takes the next
request from the line, hands it to its unit and waits for the answer,
    ↪ so a unit works on one request at a time and the
waiting happens here, where it is measured. The units are read from th
    ↪ e routes file the control plane writes (only

ready units are in it). A unit that fails to answer sends the request
    ↪ back to the head of the line for another unit
(three tries in all) and rests half a second before taking work again;
    ↪  a unit that leaves the routes finishes the
request in hand and takes no more.

HTTP on 127.0.0.1:<port>: any GET is the service's (GET /work?n=...);
    ↪ GET /_stats is this front's own reading: the
answers of the last 5 and 10 s (count, failures, the 50th, 95th and 99
    ↪ th percentiles of the response time), the line's
length and the hands working; GET /_stats?since=<seq> adds every answe
    ↪ r's response time after that sequence number

(the pieces of work the control plane's verdict measures a trial on).
    ↪ Every second the same reading is appended to the
stats file.

"""Where a unit goes: the room rule.

A machine's room is its processor less the requests of the units on it
    ↪ ; a unit goes only where its request fits, so no
machine is ever asked for more than it has. Only machines awake take n
    ↪ ew units (one booting, draining or parked takes
none). Two ways to choose among the machines that fit:

  pack    Omni's: the machine left fullest by the unit (the best fit),
    ↪  so whole machines empty out and can be parked;
          but a service of two or more units is never left on one mach
    ↪ ine alone, so one machine lost never takes the
          whole service with it
  spread  the yardstick's, as Kubernetes' own scheduler scores by defa
    ↪ ult: the machine with the fewest units of the
          service, then the one with the most room left

`place` returns the machine's name, or None when no machine awake has
    ↪ the room (the brain then wakes one)."""

```
    ↪  way
    >   B    90 deg   peak extension: the turn, where the metric flips
    ↪  (k -> -k)
    ⊤   Λ   135 deg   dispersion: above rest and easing, the ceiling h
    ↪ olds
    -   Ω   180 deg   falling through rest

    ≈   Π   225 deg   compression: below rest and settling into the ba
    ↪ sin
    <   Γ   270 deg   deepest compression: the turn at the floor
    ✦   Ψ   315 deg   re-alignment: below rest and rising, ignition ah
    ↪ ead

The four quadrants are the strokes of the closed circle (Chapters 29-3
    ↪ 0):
    I   Expansion     above rest, rising
    II  Dispersion    above rest, easing
    III Compression   below rest, falling
    IV  Re-alignment  below rest, rising

The wheel turns I -> II -> III -> IV -> I. Crossing from IV into I is
    ↪ ignition; the turn at peak extension is the
metric flip. The state is continuous through every crossing: nothing s
    ↪ witches off, nothing restarts.

The rim carries the 24 letters in their places on the face, 15 degrees

    ↪  each, clockwise from A at north.

The axle is the structural basin S. Its rest point S* solves equation
    ↪ (6): delta - alpha_s S - (3/4) beta_s S^2 = 0.

Closing the circle (Chapter 1, the Unified Circle Principle):

    X' = G(X),  X(0) in Omega           Omega is the living band: ever
    ↪ y level inside [0.05, 0.95]

"""The compass: one smooth law for every muscle, and the plug every mu
    ↪ scle is wired through.

A muscle is a plug with one wire in and one wire out. The plug reads i
    ↪ ts meters and writes its lever; all the
thinking is here, in the brain, written once for every muscle.

The plug (Plug)
  read      the service reading (response time, temperature, queue) an
    ↪ d the lever as it stands
  write     one value; the plug clips it to the cover, sends it, and r
    ↪ eads back what the device took
  restore   the lever back to the snapshot, the value read once before
    ↪  the first write; it never moves after that
  one writer if the lever is found at a value the brain did not write,
    ↪  someone else owns it: the brain stops writing
           and leaves that value alone (restoring over it would fight
    ↪  the new owner)

Two bands
  cover     the outer band, the lever's hard range (the device's or th
    ↪ e buyer's lowest and highest setting); every
           write is clipped to it, so nothing the math does can set t
    ↪ he lever outside
  compass      the service reading as a position in its band, 0 to 1 (
    ↪ 0: calm, 1: the service line); the brain pulls it
           to the bottom of the compass, the center (0.5 by default);
    ↪  the walls run to 0.05 and 0.95, and the last 5% on
           each side is cushion (10% in all) before the line

The force (CompassLaw.force), the physics of a ball in a compass with
    ↪ the right friction
  pull      K_P x (position - center): gentle near the bottom, harder
```

All patents, copyrights and trademarks filed in the USA.

```
    ↪ up the walls
  push      K_D x velocity: whatever is shoving the position (a load r
    ↪ ising, heat building) is met by an equal and
            opposite push; it is also the friction that stops the ball
    ↪  sloshing past the bottom (with K_D chosen for
            critical damping it glides to the center and stops, no ove

    ↪ rshoot, no ringing)
  smooth    the force is A x tanh(raw / A): a spring near the center t
    ↪ hat bends over and flattens into its maximum A,
            never a corner, never a hammer; the same shape the engine
    ↪ already uses for v_eff (omnicompass/core.py)
  fail up   past the 0.95 wall the up side goes to its full force at o

    ↪ nce, and the down side may not act until the
            position is back inside the compass

Two forces (antagonist pairs)
  up        a positive force adds capacity, power, cooling or speed (s
    ↪ cale out, raise a clock, start a chiller)

  down      a negative force takes it back (scale in, lower a limit, w
    ↪ arm a setpoint)
  each side has its own gain (lever units per unit of force), because
    ↪ adding and taking back do not cost the same;
  a muscle with two wires (a GPU's clock range and power limit) gives
    ↪ each side its own lever; a one-wire muscle

  carries both directions on its one lever

The frozen engine (omnicompass/core.py) and its proofs are untouched;
    ↪ this is a separate law, run as its own arm.

```
    ↪       -> surplus is pulled back smoothly

The law. Organs i hold allocations a_i of a budget A (watts, cores, ..
    ↪ .), have need d_i (the budget that would serve
their work at the engine's utilisation target rho), and a deficit ("lo

    ↪ cal deviation")
        e_i = d_i / (rho a_i) - 1        (> 0 needs juice, < 0 holds s
    ↪ urplus)
The redistribution mediator moves budget by the replicator flow
        da_i/dt = kappa a_i (e_i - e_bar),       e_bar = sum_j a_j e_j
    ↪  / A

Properties (proved in docs/CONVEYANCE_LAW.md, checked in tests/test_co
    ↪ nveyance.py):
  P1 conservation      sum_i da_i/dt = 0 exactly: the budget is moved,
    ↪  never created
  P2 gradient flow     it is the Shahshahani gradient of F(a) = sum_i
    ↪ (d_i / rho) ln a_i on the simplex sum a_i = A;

                       F is strictly concave, so F rises monotonically
    ↪  (Lyapunov function)
  P3 convergence       unique equilibrium a_i* = A d_i / D (D = sum d_
    ↪ i): every organ at the same deficit e*,
                       reached exponentially: da_i/dt = (kappa/rho)(d_
    ↪ i - a_i D/A), rate kappa D / (rho A), and the

                       linearisation has eigenvalues -kappa D/(rho A)
    ↪ < 0 (Re(lambda) <= 0, Ch. 31 §5)
  P4 bounds            organ floors and ceilings (device minimum, TDP)
    ↪  are kept by projection; budget an organ cannot
                       take because it is at its ceiling returns to th
    ↪ e others (water-filling), and budget left over

                       when every organ is at its need is held back as
    ↪  reserve, not spent
Reserve (Ch. 30 surge): R = the budget needed to cover the demand rise
    ↪  the rate tracker projects over one actuation
delay; released continuously to organs whose deficit stays positive af
    ↪ ter the flow."""

"""The v5 edge: the compass's balance point is not a fixed middle, it
    ↪ moves with each muscle's own risk.

One Edge per knob. Every decision it reads the service position (0 cal
    ↪ m, 1 the service line) and keeps the cushion the
knob needs in front of the line:

    cushion = climb x reaction + z x wobble
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
  climb     the largest rise of the position seen within one reaction
    ↪ time, per decision (how fast the service has been
            climbing lately); times the reaction, it is the rise that
    ↪ can land before the knob's own action does
  reaction  the decisions the knob takes to act: its own, not the plan
    ↪ t's (a power cap answers in one decision; a machine

            pool only once its machines have started)
  wobble    the step-to-step spread of the position over the window (d
    ↪ ivided by root 2: the spread of one step)
  z         3.09: 99.9% of steps inside the cushion

It widens at once when the need rises and narrows slowly when it falls

    ↪  (a driver doubles the following distance the
moment rain starts, and closes it slowly after). A fall (the service o
    ↪ ver its line) while, or soon after, Omni held
something back teaches the knob a floor under its cushion, forgotten s
    ↪ lowly. With memory, the worst climb and wobble the
knob has shown are kept as long as its own physics carries them.

The balance point is 1 - cushion; the wall (where the law fails up at
    ↪ once) moves with the reaction part of it. The
realms use this through realms/compass_arm_v5.py; the live controllers
    ↪  through omni_controller/ (--law v5). Pure math,
no I/O; the frozen engine (omnicompass/core.py) is untouched.

  pace      (omni-v16) the length of one reading in the knob's referen
    ↪ ce steps: the window, the narrowing, the floor's
            forgetting and the memory are given per reference step and
    ↪  kept so in time, and the wobble is the spread of
            the change over one reference step, so a knob read more of

    ↪ ten keeps every rule's time and only reads more
            often. The Kubernetes governor's reference step is its min
    ↪ ute (pace = its decision period / 60 s); at pace 1
            every value is the one given, as every engine before omni-
    ↪ v16 read it
"""

"""The immune system's self-knowledge, knob by knob (the founder's ord
    ↪ er of 25 October): Omni-Compass knows when a knob it holds
is redlining out of its band; if its own pushing cannot bring the knob
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    ↪  back and native is stronger there, it hands the knob to
native itself; if native is not stronger, it stays, because redlining
    ↪ less than native would is still a benefit against native.

  "OmniCompass's mechanism must know when something is redlining out o
    ↪ f its band when OmniCompass is on it. And if OmniCompass

  couldn't fix it to stop it redlining, then OmniCompass's own mechani
    ↪ sm must know that if native is better, then it switches
  itself to native. If native is not better, well, then it'll stay."

Each decision a knob gives three readings:

  p_omni     the knob's gauge against its own line with Omni-Compass's
    ↪  setting, as a ratio: 1 is on the line, over 1 is redlining
  p_native   the native twin's reading of the same moment under native
    ↪ 's own setting (the caller's twin of the native rule)
  moved      Omni-Compass changed the knob this decision
  at_limit   Omni-Compass's push on the knob is at the knob's own limi

    ↪ t (it cannot push further)

The rule (all in decisions, nothing tuned to a result):

  redlining   p_omni > 1 for `streak` decisions in a row
  stuck       redlining, and Omni-Compass's pushing has not brought it

    ↪  back: at its limit, or p_omni has not fallen by `relief`
               (a fraction of its reading when the redline began) since
    ↪  then
  stronger    native's twin reads lower than Omni-Compass by more than
    ↪  `margin`: p_native < p_omni · (1 − margin)
  hand back   stuck and native stronger: the knob goes to native and s

    ↪ tays there `hold` decisions, the hold doubling for each
               hand-back in a row (up to `hold_max`) and halving after
    ↪ a quiet hold
  stay        stuck and native not stronger: Omni-Compass keeps the kn
    ↪ ob (it redlines less than native would)
  return      after the hold, while native holds the knob: Omni-Compas
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    ↪ s takes it back only when its own twin reads lower than
              native's by the same margin and nothing redlines with it

The nervous system carries the answer to the organ (omnicompass/nervou
    ↪ s_system.py, `native_hold`): an organ handed to native has
no authority of Omni-Compass's until it is returned. The C++ twin is c
    ↪ pp/src/immune.cpp (tests/test_cpp_immune_parity.py)."""

```
Its purpose is security: if anything gets into Omni-Compass's brain an
    ↪ d tries to drive a system for its own ends, or
anything rogue happens, one switch in a human hand turns Omni-Compass'
    ↪ s governing off everywhere at once. It is not
the reset (the one pedal lifted all the way at the end of a run, which
    ↪  hands one governor's settings back).

Every Omni-Compass governor on a machine (the Kubernetes controller, t
    ↪ he GPU governors, any muscle they drive) obeys one
switch, in a human hand:

  OFF   the switch file exists (OMNI_MASTER_OFF, by default /tmp/omni-
    ↪ compass/OFF). Every running governor sees it at its
        next decision, puts every setting it ever wrote back to the va
    ↪ lue it read before its first write, reads each one
        back, writes its last audit line and exits. No governor starts
    ↪  while the switch is OFF.
  ON    the switch file is removed. Nothing restarts by itself: a gove
    ↪ rnor runs again only when someone starts it.

The switch is also pulled from the command line, which signals every r
    ↪ egistered governor at once so none waits for its
next decision:

  python3 tools/omni_switch.py off [--reason TEXT]    turn the whole h
    ↪ arness off, wait for every governor to restore
  python3 tools/omni_switch.py on                      allow governors
    ↪  to be started again
  python3 tools/omni_switch.py status                  OFF or ON, and
    ↪ every governor running

A governor that cannot read the switch (a filesystem it cannot reach)
    ↪ treats that as OFF: when in doubt, hand back.

If a governor dies without handing back (killed outright, the machine
    ↪ crashed, it hung), nothing it wrote may be left
```

All patents, copyrights and trademarks filed in the USA.

```
in place. So every governor records, before its first write, the exact
    ↪  commands that put every setting back, and
renews a lease every decision. The watchdog finds any governor whose p
    ↪ rocess is gone or whose lease is older than its
limit and runs those commands for it:

  python3 tools/omni_switch.py watchdog [--stale 60] [--every 10]    k
    ↪ eep watching (run it as its own service)
  python3 tools/omni_switch.py watchdog --once                       o
    ↪ ne pass

All patents, copyrights and trademarks filed in the USA.

```
    ↪  which each of them may act.

Inputs, all from the six-state engine (omnicompass/core.py, via the go
    ↪ vernor), and nothing tuned per organ:
  kappa  convergence   = 1 if push <= push_release, else push_release
    ↪ / push. This is the equation-(2) gate made

                         continuous: the further the engine is from it
    ↪ s basin, the less it may give back.
  h      basin health  = clamp((U - U_gate) / (1 - U_gate), 0, 1)
  sigma  stress ratio  = S / S*, where S* solves delta - alpha_s S - (
    ↪ 3/4) beta_s S^2 = 0 (equation 6)
  nu     unmet need    = max(0, I_U) (equation 3)

  calm                 = kappa * h * (1 - clamp(sigma - 1, 0, 1)) * (1
    ↪  - clamp(nu, 0, 1))
                         in [0, 1]; 1 means fully settled

Authority per organ:
  expand     may the organ add capacity or performance. Always yes, ex

    ↪ cept during a security hold.
  contract   may it give capacity or performance back. Only when calm
    ↪ >= the organ's reversibility threshold
             (theta_pods 0.5, theta_nodes 0.7: a node costs a boot to
    ↪ reverse) and the SLO is clean.
  step       fraction of the organ's surplus it may shed this decision

    ↪ . Equals calm.
  envelope   for continuous organs, the allowed range:
               cpufreq ceiling (fraction of cpuinfo_max) in [1 - 0.35
    ↪ calm, 1];
               GPU power limit (fraction of max) in [1 - 0.30 calm, 1]
    ↪ ;

               site power cap in the living band of its own range (not
    ↪ hing fixed: the device's own floor and top);
               traffic-shift fraction in [0, 0.5 calm];
               cooling supply-air setpoint (C) in [18, 18 + 9 calm].
             Heat above 0.96 forces the frequency and GPU ceilings dow
    ↪ n to 1 - 0.35 x excess.
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
  batch      admit held work only if calm >= 0.5 and power stress < 0.
    ↪ 9; pause pausable work if sigma > 1, power
             stress >= 0.95, or heat >= 0.96.
  rollback   the engine's rollback authorisation (S high, U falling, o
    ↪ r a security hold).

Global rules, applied last:
  - observe: every authority is computed and logged; execute is False
    ↪ everywhere.
  - kill: no authority at all.
  - security hold: no capacity organ may expand. Cooling is the one pr
    ↪ otective organ: "expand" there means more

    cooling, which adds protection and no capacity, so it stays allowe
    ↪ d.
The safety shield (omnicompass/shield.py) stays downstream and can sti
    ↪ ll veto any action.

```
The frozen fleet law (adapter.AllocationLaw, FLEET_MODE) uses one numb
    ↪ er, rho*, both as the HPA target (how busy each
pod may run) and as the node-sizing target (how busy each machine may
    ↪ run). Saving machines therefore always meant
running pods hotter, which is where response time was lost. This law s
    ↪ eparates the two:

  pods      HPA target = rho* from the engine (equation: rho* = clamp(
    ↪ rho0 - kI I_U - kE E, rho_min, rho0)), with
            speed constants (rho0 near the latency knee) and the respo
    ↪ nse-time nerve feeding the queue observation
  machines  sized to what the pods ask for, not to how busy they are:

            n_up   = ceil(requests / (cores * ALLOC) * (1 + headroom_u
    ↪ p)) + ceil(kq * q * n)
            n_keep = ceil(peak requests over the last `window` decisio
    ↪ ns / (cores * ALLOC) * (1 + headroom))
            added at once when n < n_up (a pending pod costs response
    ↪ time);

            removed one per decision only when n >= n_keep + band for
    ↪ dwell decisions, no sooner than after_add
            decisions after an addition, and only while the engine's e
    ↪ quation (2) push <= push_release
  ahead     while requests are rising, n_up += ceil(antic * trend * n)
    ↪ , trend = relative rise over antic_lag

            decisions (anticipation: machines boot before the pods tha
    ↪ t need them are created; antic = 0 disables)
  power     cap = 1 whenever work is waiting or pods are busy above ca
    ↪ p_busy; otherwise cap_idle
            (a cap slows service: S = S0 / cap, so capping a busy mach
    ↪ ine always costs response time)

The engine state (E, U, I_U, S, B, B_dot) is evolved by omnicompass.co
    ↪ re unchanged; only this mapping is new.

"""The verdict: Omni-Compass moves a knob only where it measures that
    ↪ the muscle loses nothing by it.

Omni-Compass sits on top of a muscle that already works (a card's firm
    ↪ ware, an autoscaler, a chiller's loop). It does not
replace that muscle, and it has no reason to move the muscle's knob un
    ↪ less moving it costs the muscle nothing. The
verdict is how the brain finds that out, on the muscle itself, before
    ↪ it acts and again from time to time:

  steps     the knob's settings from native outward, in whole steps (s
    ↪ tep 0 is native: the muscle as it runs alone)
  cost      what each setting costs the muscle's own work, measured pe
    ↪ r piece of work (a card: the milliseconds it spends
            on one request, the wait in the queue left out, so more tr

    ↪ affic is never mistaken for a slower card)
  probe     while the service is calm, a paired trial: first the knob
    ↪ at native until min_samples pieces of work are
            measured (the reference, fresh, under the same traffic), t
    ↪ hen at one step past the deepest step already
            allowed until min_samples more are measured

  judge     the trial step's median cost against the reference's: no h
    ↪ igher (within the measurement's resolution,
            tolerance) and the step is allowed; higher and it is refus
    ↪ ed, the knob goes back, and that step is not tried
            again until recheck decisions have passed (the work may ha
    ↪ ve changed). A trial that sees the service leave
```

All patents, copyrights and trademarks filed in the USA.

```
            calm is abandoned, and the knob goes back at once
  allowed   the compass may move the knob only between native and the
    ↪ deepest allowed step; where no step is allowed, the
            verdict is "left native" and the knob is never moved

  stepwise  for a knob that is slow to move back (a machine given back
    ↪  takes minutes to return), incremental=True runs
            the reference at the deepest step already allowed instead
    ↪ of at native, and judges the trial step against
            both that reference and the cost first measured at native,
    ↪  so steps can never add up past the allowance

The verdict never makes the knob more aggressive than the law: it only
    ↪  narrows where the law may go. Every probe and
every judgement is returned to the caller for the audit.

  in words  (Omni v7, judge="interval": the reports' own words, GAIN,
    ↪ EVEN and LOSS, as the code that steers the knob,

            docs/omni_v5/NEXT_VERSION_PLAN.md section 1) the trial ste
    ↪ p is read exactly as a report reads a row: the 95%
            interval of its change in cost, on the logarithm of each p
    ↪ iece of work's cost (so a heavy tail does not
            decide it), d = mean ln c_trial − mean ln c_ref ± 1.96 se.
    ↪  The interval wholly above zero is a LOSS: the step

            is refused and undone, whatever the allowance says. Wholly
    ↪  below zero is a GAIN, and across zero is EVEN.
            While the interval is wider than the allowance (its half-w
    ↪ idth over τ = ln(1 + tolerance)) the trial measures
            on, up to three times min_samples. A GAIN or an EVEN step
    ↪ is allowed only if both estimates of its change

            are within the allowance: the median (the guard of the eng
    ↪ ines before v7, kept) and the mean of the log
            costs, d ≤ τ. A stepwise step is read, the same way, again
    ↪ st the costs first measured at native. On noisy
            work this refuses a step that truly costs 3% more against
    ↪ a 2% allowance about a quarter less often than the
```

"""The compass law on every realm muscle (omnicompass/compass_law.py):
    ↪  each plant's knob held by its own compass.

Each plant's service is read as one position in its compass (0 calm, 1
    ↪  the line): the worst of its queue or lateness, its
load above half, and, for a storage site, its draw on the grid connect
    ↪ ion above half. The last period in violation
reads as past the wall (fail up). The compass's force moves the knob:
    ↪ a positive force adds capacity, power, cooling or

protection, a negative force gives it back, each knob inside its own c
    ↪ over. At the kill every knob returns to native.

Knob by plant (the override key the plant already obeys, its native va
    ↪ lue, its cover, and which way is "more"):
  compute_pool   power: limit share 0.4-1; replicas-type: the HPA targ

    ↪ et held at native (loosening it past the
                 operator's own costs the service time, the same rule
    ↪ as the card's speed floor); machine pools: one
                 machine released while the force is clearly down and
    ↪ the machines left cover the recent peak with
                 margin (RELEASE_MARGIN); admission: native

  thermal_zone   setpoint between the band's stress (colder, more cool
    ↪ ing) and calm ends; units: one released while the
                 force is clearly down; power: native (a cooling cap m
    ↪ oves heat later, never away)
  energy_storage reserve between the band's ends (a lower reserve give
    ↪ s the battery to the site); power: native

  motion_axis    speed and effort: 0.4-1
  process_loop   setpoint from native toward the band's calm end; actu
    ↪ ator range 0.3-1; power 0.4-1

# ---------------------------------------------------------------------
    ↪ ------------------------------------------------
# MAX, the work edge: the default brain (the founder's orders of 11 an
    ↪ d 12 October). Every muscle is pushed toward its
# own limit to do the most work, faster; never past its limit and neve

    ↪ r below native (native's own setting is always one
# of the brain's choices, so a muscle native already runs flat out sta
    ↪ ys native, wired and watched). The energy that
# takes is reported as power given, beside the work and the speed it b
    ↪ ought. One pedal: push for more, lift off for
# less, and lifting hands the setting back toward native.

#
#   compute pool   the machines the forecast needs are started before
    ↪ the rush lands: the recent peak arrivals widened
#                  by the largest rise this pool has shown within one
    ↪ machine start, plus the standing queue, at the edge
#                  utilisation. The HPA target is lowered just enough

    ↪ that the operator's own autoscaler starts them (a
#                  machine pool: a floor under its cluster autoscaler)
    ↪ . Never fewer machines than native would keep; the
#                  power cap and admission stay native (full clock, ev
    ↪ ery request admitted)
#   cooled zone    cooled ahead of the heat: the setpoint goes from th

    ↪ e operator's toward the band's cold end as the
#                  room nears its limit or its cooling nears flat out,
    ↪  both read ahead by the cooling's own answer time;
#                  never warmer than native
#   battery site   the charge is held for the line instead of spent on
    ↪  the first minutes of load, and only the draw

```
    wobbles; a battery that clips its own line counts the power it can
    ↪  still clip). With no room, the machines this
    brain added go back at once, never below what the pool's twin runs
    ↪  (the brain's model of native: the same pool under
    its own autoscaler alone, on the same arrivals), so a pool never h
    ↪ as fewer machines than native and the lines never

    carry more of this brain's power than they have room for. Nothing
    ↪ is taken from one muscle to give to another: the
    max never shaves (the tune-down does that, on the dial).

    A battery's charge counts as room on its line only while it lasts:
    ↪  a site whose battery covers its draw now, but

    whose charge above its floor runs out before power granted now cou
    ↪ ld be handed back, has as room only its line less
    its whole draw (the line a decision later carries all of it). And
    ↪ every room wired by its setpoint has a twin too:
    the same room under its operator's setpoint, warmed by native's he
    ↪ at (each pool's twin in place of the pool, every

    other source as it is), so the brain knows the temperature native
    ↪ would leave it at and never leaves it warmer."""

"""A GPU card on its real physics, its own firmware, and the two-wire
    ↪ plug (evidence class S: a model, not a meter).

The card
  clock     f, a share of the top clock (1.0), moved by the firmware i
    ↪ n bins of 0.9% (about 15 MHz on a 1.7 GHz part)
  power     P = idle + leakage(T) + P_dyn x busy x f x V(f)^2, with V(
    ↪ f) = 0.6 + 0.4 f: dynamic power rises with the
            clock and with the square of the voltage the clock needs,
    ↪ so the top of the clock range costs the most
  heat      C dT/dt = P - (T - T_amb) / R_th; leakage rises with tempe
    ↪ rature
  work      requests arrive (a slow wave, bursts, noise, drawn from th
    ↪ e seed); the card serves f x mu per second;
            a request's response time is its wait plus its service tim
    ↪ e

The firmware (native, what ships on the card), 50 times a second
  boost     while there is work and room, raise the clock one bin, up
    ↪ to the clock ceiling
  hammer    while the draw is over the power limit, or the chip is ove
```

All patents, copyrights and trademarks filed in the USA.

```
    ↪ r its slowdown temperature, drop three bins
  So the clock saws against the limit for as long as the work keeps co
    ↪ ming: up a bin, knocked down three, up again.

The work
  memb      the share of a request's time at the top clock spent waiti

    ↪ ng on memory, which does not speed up with the
            clock: 0 is compute-bound work (large matrix products, the
    ↪  bench's pinned workload), 0.85 is typical of AI
            token generation (each token streams the model's weights f
    ↪ rom memory). The card serves 1 / ((1 - memb) / f
            + memb) of its top speed

The arms: each base alone, and the same base with Omni-Compass on top
    ↪ (Omni never runs the card itself)
  native    the card as shipped: power limit 150 W, clock ceiling at t
    ↪ he top, firmware alone
  omni      native + Omni-Compass on top, through two wires (omnicompa

    ↪ ss/compass_law.py): the clock ceiling is the up wire (how
            high boost may push), the power limit is the down wire (th
    ↪ e lid, set just above what the ceiling draws,
            never under the card's own busy draw). The compass's readi
    ↪ ng is the response time as a position between the
            bare service time (0) and the service line (1); the brain

    ↪ pulls it to the center. The verdict
            (omnicompass/verdict.py) decides how far the ceiling may g
    ↪ o: a step down is allowed only after a paired
            trial shows it costs each request at most ALLOW of the car
    ↪ d's own time on it; where no step passes, the
            ceiling stays where the firmware has it. Both wires are re

    ↪ stored to their snapshot at 90% of the run
  cap       a fixed power cap set by the operator and left (105 W, 70%
    ↪ ), firmware alone under it
  cap_omni  the cap + Omni-Compass on top: the same law, the lid never
    ↪  above the operator's cap

"""Realm harness: every muscle native, watched and governed; every rea
    ↪ lm, and the whole tower, as one organism.

Arms, all on the same seed (the same demand, weather, disturbances):
  native  the plant and its native controller alone
  watch   the frozen governor reads the plant every period and writes
    ↪ nothing; must equal native exactly
  omni    the frozen governor holds the muscle's one knob; at 90% of t
    ↪ he run it is killed, the knob returns to the

          native controller, and the harness checks that it did

The governor is omnicompass.adapter.Governor, unchanged (the engine wi
    ↪ th u = 0, the stack law, the reset).

Single muscle: one plant, one governor reading that plant.

Organism: all the plants of a realm (or the whole tower) on one 15 s c
    ↪ lock, coupled: the electrical power of compute, motion
and process plants is heat in the realm's thermal zones; the organism'
    ↪ s load swing is load on its storage sites; the
zones' temperature is the ambient every other plant reports. One gover
    ↪ nor reads the organism's aggregate and its one

directive sets every muscle's knob.

Primary outcome per seed: work per energy, omni against native: (work_
    ↪ omni / work_native) / (energy_omni /
energy_native) - 1. For an organism, work is the mean over its plants
    ↪ of work_omni / work_native (their work units

differ) and energy is total joules. Guardrails: work not lower by more
    ↪  than 1%; the share of periods in violation not
higher by more than 1 percentage point. Labels by rule (label()).

"""Realm plants: the machines the muscles act on (evidence class S: de
    ↪ clared models, not meters).

Five plant models. Each one carries its own native controller and runs
    ↪  correctly with no Omni at all:

  compute_pool    servers, nodes, GPUs, robots, radio cells or workers
    ↪  serving a request stream; native: the Kubernetes
                  HPA rule (desired = ceil(n * utilisation / target),
    ↪ 10% tolerance, scale-down stabilisation window,
                  start-up delay), a fixed admission limit, full clock
  thermal_zone    a data hall or building zone cooled by staged units;
    ↪  native: PI on a fixed setpoint, units staged to
                  the load, chiller COP from supply and outdoor temper
    ↪ ature
  energy_storage  a site with load, solar and a battery behind a grid
    ↪ connection; native: self-consumption above a
                  fixed reserve
  motion_axis     a joint, flight axis, spacecraft axis or vehicle doi
    ↪ ng point-to-point moves from a task queue;
                  native: PID with feedforward at full speed, motor he
    ↪ ating and derating
  process_loop    a first-order process with dead time (level, pressur
    ↪ e, chamber temperature, feeder voltage);
                  native: PI on a fixed setpoint, pump or heater power
    ↪  from the actuator

A muscle is one knob of one plant. Omni may hold that knob and only th
    ↪ at one; the native controller keeps the rest.
Omni commands a knob the way the shipped controller commands its organ
    ↪ s (omni_controller/controller.py,
omni_controller/muscles.py), through the nervous system's authority (o
    ↪ mnicompass/nervous_system.py, from_governor):

  expand     adding capacity, performance or protection is always allo
    ↪ wed (except during a security hold)
  contract   giving any of it back (fewer machines, a lower speed or p
    ↪ ower limit, a warmer setpoint, a lower reserve
             of protection) only while the organ has contraction autho

    ↪ rity (calm >= the organ's threshold, senses live)
             and the plant's service has been clean for the last three
    ↪  decisions (the SLO reflex); continuous organs
             shed at most the calm fraction of their surplus per decis
    ↪ ion, discrete organs one unit, through a release
             gate (nothing waiting, and after the release the rest run

    ↪ s at or under the engine's utilisation target)
  fail up    while service is breached, the knob returns to the native
    ↪  controller at once
  pacing     admission muscles are batch pacing (the live batch_pace m
    ↪ uscle): one muscle's work suspended per decision
             while power stress >= 0.95 or heat >= 0.96 or the nervous

    ↪  system calls a pause; one resumed per decision
             once power stress <= 0.8 and heat < 0.90 (realms/harness.
    ↪ py, pace)

By plant and knob:
  compute_pool  replicas and HPA-type knobs: the HPA target written as

    ↪  min(rho*, the operator's target), never tighter,
                held for one autoscaler window (the live controller's
    ↪ rule); machine pools (Cluster Autoscaler native):
                the node release gate; power: the GPU or CPU-frequency
    ↪  envelope, never under the work's draw plus 30%,
                and never on a request-served pool (the live controlle
```

All patents, copyrights and trademarks filed in the USA.

```
    ↪ r: throttling it saves no energy, only adds
                wait); admission: batch pacing of pausable work only (
    ↪ request traffic is never paused)
  thermal_zone  setpoint: the live cooling law (warm while cool, cold
    ↪ as heat rises, inside [stress, stress + band x
                calm]); units: the release gate; power: the site power

    ↪  envelope above the load plus 10%; admission:
                paced, the migratable 10% is shed
  energy_storage reserve by power stress (released under stress, held
    ↪ when calm only with authority); peak-shave
                ceiling at rho* of the connection (expand only); batte
    ↪ ry power: the site power envelope; admission:

                paced, the flexible share is deferred; resumed, it is
    ↪ caught up
  motion_axis   speed: up at once to demand, down by the calm share of
    ↪  the surplus; effort: the power envelope;
                admission: paced, no new move starts
  process_loop  setpoint: toward the efficient end of its band by the

    ↪ calm share; actuator range: as motion speed;
                power: the site power envelope above use plus 10%; adm
    ↪ ission: paced, 10% is shed

Every disturbance trace is drawn from the seed when the plant is built
    ↪ , so all arms of a seed see the same ones.

Meters (work, energy_j, viol, steps) are kept by the plant from its ow
    ↪ n state; Omni never supplies them.

"""The brain's own verdict on one live knob, in real time (the founder
    ↪ 's order of 9 October 2026).

Every knob starts in watch: one wire out, nothing written. It is writt
    ↪ en only between native and the deepest step a paired
trial on the stack itself has allowed under the declared objective, an
    ↪ d a step that fails its trial is not taken. The
trial, the judgement, the allowance and the recheck are the frozen eng
    ↪ ine's (omnicompass/verdict.py, Omni v3, byte for

byte); this module gives that Verdict the knob's notch, the cost it ju
    ↪ dges and the condition under which a trial of this
knob is fair. Nothing in the engine changes.

  two directions   spend (more of the resource: a bigger ceiling, more
    ↪  consumers, more connections) and give back (less:

                   fewer connections, a smaller pool or cache), each i
    ↪ ts own Verdict with its own steps outward from native.
                   Restoring native is never a step: the knob may alwa
    ↪ ys be moved back toward the operator's setting.
  the condition    a give-back step is tried while the service is calm
    ↪  and the stack's own give-back condition holds (the

                   engine's rule: a trial is never run under stress);
    ↪ a spend step is tried while the compass asks to spend
                   and the stack's own spend condition holds (a cache
    ↪ full and missing, messages waiting, clients queued),
                   because that is the only time a spend can show what
    ↪  it buys. A give-back trial once started runs on
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
                  until its samples are in unless the service leaves
    ↪ calm, when it is abandoned (the engine's rule). A
                  spend trial runs to its samples whatever the compas
    ↪ s's force: the spend's own effect calms the service
                  within seconds, and a trial ended on that calm coul
    ↪ d never be judged (the first counted set of 10

                  October 2026 abandoned every Kafka spend trial that
    ↪  way; amendment 3 in the five preregistrations). Only
                  the wall (a fail-up) or the engine's own time limit
    ↪  ends a spend trial early.
  the cost        one sample a second from the stack's own readings.
    ↪ Under the resource objective, the preregistered

                  reading of the Omni index, cost = resource held x h
    ↪ ost CPU busy share x latency / work: a step passes only
                  if the service gained outweighs the resource and CP
    ↪ U spent, by the index's own arithmetic (a geometric mean
                  of the four ratios no lower than one is the same st
    ↪ atement). Under the service objective cost = latency /

                  work: the resources are shown and not judged. The a
    ↪ im is the lower cost; "no higher within the tolerance" passes,
                  which is the engine's judge, so a step that buys no
    ↪ thing and costs nothing is allowed and a step that costs
                  more than it buys is refused.
  the hold        during a trial the knob stands at the phase's value

    ↪  whatever the compass asks: the reference at the
                  deepest step already allowed (native at first), the
    ↪ n the trial step one notch further. Between trials the
                  compass moves the knob by its own law, clamped to t
    ↪ he allowance. A fail-up never spends beyond the
                  allowance; toward native it is always free.

  the record      every trial, allowance, refusal and abandonment is
    ↪ kept for the audit, with the counts and the state:
                  "left native" (no step allowed in either direction)
    ↪  or "acting" with the allowance.

"""Omni-Compass on top of CityLearn's own controller: an independent,
    ↪ recognized simulator we did not write.

CityLearn (Intelligent Environments Lab, University of Texas at Austin
    ↪ ; github.com/intelligent-environments-lab/citylearn,
MIT license) simulates districts of real buildings from measured data:
    ↪  each building's load, its solar panels, and its
battery, hour by hour for a year. It ships its own controllers. Its ru

    ↪ le-based controller (citylearn.agents.rbc.BasicRBC)
is the native arm: it charges and discharges every battery by the hour
    ↪  of the day.

Arms, the same district, the same year, the same weather and loads:
  native  CityLearn's BasicRBC alone
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
  omni    the same BasicRBC, with the compass law (omnicompass/compass
    ↪ _law.py) on top of its electric battery commands only (a
          cold or hot water tank is a thermal muscle with its own read
    ↪ ing and stays native). The reading is the
          district's draw without its batteries in the coming hour, re
    ↪ ad from the same hour of the past week's days

          (the demand the batteries answer, not their own effect; caus
    ↪ al: only hours already seen; omni-v9); its band is
          the 10th to the 90th percentile of the past week's draw. The
    ↪  compass's force moves every battery command the same way:
          a positive force (the district drawing hard) pushes toward d
    ↪ ischarge, a negative force (a quiet district)

          toward charge, by at most GAIN of the command's range, alway
    ↪ s inside the battery's own limits [-1, 1]. At
          KILL_AT of the year Omni-Compass hands every command back to
    ↪  the native controller, and the file checks it did

Scored by CityLearn's own evaluation (env.evaluate): every cost functi

    ↪ on as CityLearn defines it, each the controller's
value over the value with no battery at all (CityLearn's direction is
    ↪ lower for every one). Each is read by the one key
(tools/readings.py): energy not served and time uncomfortable are miss
    ↪ es, a rise is a LOSS; the bill, the electricity, the
carbon and the power held (its peaks, swings and unevenness) are resou

    ↪ rces, a fall is a cut and a rise is power given.
Nothing here is scored by Omni-Compass's own code.

  python3 tools/run_citylearn.py --datasets citylearn_challenge_2022_p

```
(docs/CPU_POWER_PREREGISTRATION.md).

The machine as it runs: the kernel's frequency governor as shipped (sc
    ↪ hedutil, or the processor driver's own) choosing the
clock every few milliseconds under a fixed ceiling, the processor's en
    ↪ ergy counter (RAPL, /sys/class/powercap) ticking in

microjoules, and a CPU-bound service answering requests offered at a f
    ↪ ixed rate that steps up and down. The governor is the
native controller here; it keeps running in both arms.

  native  the machine as found: the governor as shipped, the frequency
    ↪  ceiling where the operator left it (the top)

  omni    the same machine, the same governor, with the compass law (o
    ↪ mnicompass/compass_law.py) on one knob, the frequency
          ceiling (cpufreq scaling_max_freq, written through the kerne
    ↪ l's own interface on every CPU), inside the cover
          [half the top clock, the top]: the compass reads the service
    ↪ 's own request latency on a band from 0 to the response

          line and holds it at 40% of the line; a slow service raises
    ↪ the ceiling by notches, calm gives one notch back after
          a dwell, at 95% of the line the ceiling goes to the top at o
    ↪ nce (fail up); the brain's own verdict
          (tools/knob_verdict.py around the engine's omnicompass/verdi
    ↪ ct.py) tries every notch down on the machine itself

          before it is allowed, under the declared objective, and a no
    ↪ tch that does not pay is not taken; the ceiling is
          handed back to the operator's at the end and read back; a ce
    ↪ iling found at a value Omni did not write stops it
          writing (one writer); the master switch and the lease (omnic
    ↪ ompass/master.py) hand back if Omni dies

Gauges from the service's own records (every request's latency), the p
    ↪ rocessor's energy counter (joules over the window,
class P: the processor's own meter), a wall plug where one is fitted (
    ↪ WALL_METER, tools/wall_meter.py: the whole machine,
independent of Omni), the kernel's own frequency readings and /proc/st

"""Omni-Compass on top of a Kafka consumer group's operator-set size (
    ↪ docs/KAFKA_PREREGISTRATION.md).

Apache Kafka as shipped (one KRaft broker on the machine, its server.p
    ↪ roperties untouched but for the log directory) carries
a topic of 8 partitions. A producer offers messages at a stepped rate,
    ↪  the same in both arms; a consumer group reads them,
spends a declared service time of CPU on each (the work the messages a

    ↪ re for), and records each message's end-to-end
latency, produce to consume. An operator sets the consumer count once;
    ↪  that fixed number is the native controller here.

  native  the consumer group at the operator's count (2 consumers) for
    ↪  the whole run

  omni    the same group, with the compass law (omnicompass/compass_la
    ↪ w.py) on one knob, the consumer count, inside the
          cover [1, 8] (never under one consumer, never more consumers
    ↪  than partitions): the compass reads the group's own
          end-to-end latency on a band from 0 to the response line and
    ↪  holds it at 40% of the line; the service slow and
```

All patents, copyrights and trademarks filed in the USA.

```
          messages waiting add consumers; calm gives back one idle con
    ↪ sumer a second (above the operator's count, calm with
          nothing waiting gives one back with no idle test; idle is a
    ↪ full second with no message: store fix of 25 October);
          at 95% of the line every consumer the
          topic can use is started at once (fail up); the count is han
    ↪ ded back to the operator's at the end and read back

Gauges from the consumers' own records (every message's latency), the
    ↪ group's lag (produced minus consumed) and the
host's /proc/stat (CPU seconds, the consumers' and the compass's own c
    ↪ ost, counted against Omni). No energy is claimed
beyond the host's CPU seconds. Every row is reported, losses included.

  python3 tools/run_kafka.py --setup                      # start a br
    ↪ oker and make the topics (the workflow does this)

    ↪ ice slow with messages waiting adds consumers,
    ceil(force / 0.1) at a time; calm gives back one idle consumer a s
    ↪ econd, after the dwell; past the wall, every
    consumer the topic can use at once.
    Store fix of 25 October: above the operator's own count (snapshot)

    ↪ , calm with no more waiting than the group takes in one
    poll round (POLL_RECORDS a consumer: the messages in flight betwee
    ↪ n the producer and the consumers, which keep the lag
    above zero in 388 of 389 calm seconds of an omni-v16 arm) gives on
    ↪ e consumer back, HANDBACK_DWELL_S after the last change,
    with no idle test (every consumer of a topic keyed round-robin has

    ↪  work, so the idle test held a consumer added above
    native to the end of the arm). Below the operator's count the idle
    ↪  test and an empty backlog stay. A second in which the
    group consumed nothing (consumed 0: before the producer starts, or
    ↪  a rebalance) says nothing about the demand: nothing
    is given back in it."""

"""Omni-Compass on top of a robot arm's own position servos, in MuJoCo
    ↪  (docs/ROBOTICS_PREREGISTRATION.md).

MuJoCo (Google DeepMind) integrates the arm; MuJoCo Menagerie supplies
    ↪  the robot as its maker describes it, with the
position servos the model ships with. The task is a pick-and-place cyc
    ↪ le between fixed joint-space waypoints scaled to
each robot's own ranges, played as a minimum-jerk trajectory with a pl
    ↪ anned duration, under a time line (the slowest

cycle the task allows). Arms:
  native  the shipped servo tracks the trajectory at its planned speed
    ↪  (speed override 1.0)
  omni    the same servo and trajectory, with the compass law (omnicom
    ↪ pass/compass_law.py) on one knob, the speed override,
          read from the cycle's time margin: with slack the override e

    ↪ ases down (gentler motion, less torque, less
          energy); as the margin shrinks it comes back up; past the wa
    ↪ ll it is full speed at once. Guards: override in
          [0.5, 1.0], at most 0.01 per control tick (100 Hz), handed b
    ↪ ack to 1.0 at the end of every cycle and read back.
Before the counted cycles, one paired trial in native mode (a cycle at

    ↪  override 1.0 and one at 0.8, neither counted) asks
the robot's own figures whether a slower cycle costs less energy at al
    ↪ l, standing draw included; if it does not, the
override is left native for that robot and the result reads "nothing f
    ↪ or Omni to move".
Energy is a declared model, the same for both arms, from MuJoCo's own
```

```
    ↪ joint torques and velocities: mechanical work
|torque x velocity|, copper heating torque^2 x C (I²R, C declared per
    ↪ robot), and a standing draw (declared per robot) drawn for
the whole takt (the time line), moving or waiting, as a robot on a lin
    ↪ e is: the unit is energy per takt. The planned speed
is set per robot, before any Omni run, as the fastest at which the rob

    ↪ ot's own servo tracks the task within 0.05 rad. Every
cycle's record is written; the report (MUJOCO.md) gives each gauge its
    ↪  word by the preregistration's aims (GAIN, EVEN,
LOSS, or power given for a resource spent that rose: tools/readings.py
    ↪ ).

An independent, recognized simulator and data set: pandapower (Fraunho
    ↪ fer IEE and the University of Kassel; BSD) solves
the AC power flow; SimBench (the German benchmark grids, with a year o
    ↪ f 15-minute load, solar and wind profiles) gives
the grids and their year. Both are someone else's work; nothing here m
    ↪ odels the grid.

  native  the substation's on-load tap changer holds the medium-voltag
    ↪ e busbar at its setpoint (1.00 per unit) inside a
          deadband of half a tap step, one tap per step at most; solar
    ↪  and wind at unity power factor (as SimBench has
          them). This is how a utility runs it on its own.
  omni    the same tap changer, with the compass law (omnicompass/comp
    ↪ ass_law.py) on top of its setpoint: it reads the
          worst voltage margin anywhere in the grid (the bus nearest e
    ↪ ither limit, 0.95 and 1.05 per unit) and moves the
          setpoint inside [0.97, 1.03]: down while every bus has room
    ↪ (conservation voltage reduction), away from the
          nearer limit as soon as one bus nears it, and straight back
    ↪ to native at a violation. At KILL_AT of the year
          the setpoint is handed back. Every move is one whole tap; a
    ↪ move toward saving needs a full week seen under the
          present setpoint whose worst moment still leaves every bus M
    ↪ ARGIN after one more tap; a move away from a limit
          is at once, once the utility's tap changer has reached the p
    ↪ resent setpoint.

Scored by pandapower itself, the same grid and the same year in both a
    ↪ rms:

  energy drawn from the upstream grid (MWh), line and transformer loss
    ↪ es (MWh), bus-hours outside [0.95, 1.05],
  tap operations (wear), and the lowest and highest voltage seen.

Loads: SimBench's loads are constant power. Lowering the voltage saves
    ↪  energy only where a load draws less at a lower
```

```
voltage, so the run is made twice: with a declared ZIP mix (40% consta
    ↪ nt impedance, 30% constant current, 30% constant
power, a common residential mix) and with SimBench's own constant-powe
    ↪ r loads, where only losses can change.

"""Omni-Compass on top of a database's own connection pooler (docs/POS
    ↪ TGRES_PREREGISTRATION.md).

PostgreSQL (the PostgreSQL Global Development Group) runs as the distr
    ↪ ibution ships it; PgBouncer (its own project) sits
in front of it in transaction pooling with the pool size it ships with
    ↪ , 20 server connections; pgbench (PostgreSQL's own
benchmark) offers the load. That is native: the pooler's fixed pool is
    ↪  the DBA's one setting, made once.

omni is the same database, the same pooler and the same load, with the
    ↪  compass law (omnicompass/compass_law.py) on
one knob: the pooler's pool size, written through its own admin consol
    ↪ e (SET default_pool_size), inside the cover
[2, 90]. The reading is the service time the pooler itself reports eve

    ↪ ry second (transaction time plus the time clients
waited for a server, per transaction), or the share of its clients que
    ↪ ued for a server scaled to the line, whichever is
larger (amendment 1), on a band from 0 to the response line. Past the
    ↪ wall the knob is handed back to
the pooler's own setting at once (fail up). At the end it is handed ba

    ↪ ck and read back.

Load: pgbench at a fixed client count, rate-limited, the rate stepping
    ↪  one notch at a time (1 2 3 2 3 4 5 6 5 4 3 2 1 2
1) with the base rate set before the counted runs by one native-only r
    ↪ un with no rate limit (the peak notch offers

native's own unlimited capacity). Both arms run the same steps, paired
    ↪ , the order alternating between repetitions.

Gauges (from pgbench's per-transaction log, PgBouncer's SHOW POOLS and
    ↪  the host's /proc/stat): work inside the
response line (transactions a second whose latency, lag included, was
```

All patents, copyrights and trademarks filed in the USA.

```
    ↪ within the line), throughput, p50/p95/p99
latency, failed transactions, server connections alive (the "machines"
    ↪ ), the host's CPU busy share and CPU-seconds.
There is no watt-meter on a GitHub runner: nothing here is an energy c
    ↪ laim.

Amendment 2 (docs/POSTGRES_PREREGISTRATION.md, declared before the sec
    ↪ ond counted set): the console is read over one
connection held for the whole arm (class Console, the server's own wir
    ↪ e protocol) instead of a psql process launched for
every reading, which was about five launches a second in the omni arm
    ↪ at about 50 ms of CPU each and was the CPU the

first counted set charged to Omni; the queue line: a server is taken b
    ↪ ack (the calm give-back and the slow-inside-the-server
shrink alike) only while the pooler's clients waited for a server unde
    ↪ r one percent of its time in the last second and a
transaction was served, and while they waited one percent or more one
    ↪ server a second is added back, up to the pooler's own

setting; the harness's own CPU is recorded beside the host's.

Usage:
  python tools/run_pgbench.py --setup                      # create th
    ↪ e bench role and database (needs the postgres user)
  python tools/run_pgbench.py --workloads tpcb --reps 3 --out out

  python tools/run_pgbench.py --report-only all --out all  # re-read f
    ↪ inished <workload>.json files and write PGBENCH.md

"""Omni-Compass on top of a Redis cache's operator-set memory ceiling
    ↪ (docs/REDIS_PREREGISTRATION.md).

Redis as shipped, with the two settings an operator sets once for a ca
    ↪ che: a memory ceiling (maxmemory) and the eviction
rule (allkeys-lru). An application in front of it asks for keys drawn
    ↪ from a working set that widens and narrows over the
run; a hit is answered by Redis, a miss costs the application a trip t

    ↪ o the store behind the cache (a declared fixed
delay) and the value is written back. The operator's fixed ceiling is
    ↪ the native controller here.

  native  Redis at the operator's ceiling (64 MB) for the whole run
  omni    the same Redis, with the compass law (omnicompass/compass_la

    ↪ w.py) on one knob, the memory ceiling, through Redis's
          own console (CONFIG SET maxmemory), inside the cover [16 MB,
    ↪  512 MB]: the compass reads the application's own
          request latency (hits fast, misses slow) on a band from 0 to
    ↪  the response line and holds it at 40% of the line;
          misses with the cache full push the ceiling up (a miss with

    ↪ room to spare is a cold miss, which no ceiling can
          mend), calm gives memory back 8 MB a second when nothing is
    ↪ being evicted; at 95% of the line with the cache full
          a quarter of the cover is added at once (fail up); the ceili
    ↪ ng is handed back to the operator's at the end and
          read back; a ceiling found at a value Omni did not write sto

"""Omni-Compass on top of a drone swarm's own autopilots (docs/SWARM_P
    ↪ REREGISTRATION.md).

The simulator is gym-pybullet-drones (University of Toronto, DSL; MIT
    ↪ License): PyBullet integrates every quadrotor from
the Crazyflie 2.x model the package ships (mass, inertia, motor consta
    ↪ nts, drag, ground effect and downwash), and its
shipped position controller (DSLPIDControl, one per drone) flies it. N

    ↪ othing in it is ours. A fleet of N drones flies
K delivery missions each from a depot: climb, cruise to a target, hove
    ↪ r, cruise back, descend, land, next mission.

  native  every drone's shipped autopilot at the planner's cruise spee
    ↪ d (1.0 m/s): the mission as the fleet flies it today

  omni    the same autopilots and missions, with the compass law (omni
    ↪ compass/compass_law.py) on one knob, the cruise
          override, inside the autopilot's own limits: the compass rea
    ↪ ds each drone's tracking error (how far it is behind
          the point it was told to be at) on a band from 0 to the decl
    ↪ ared safe error, and spends slack by flying faster

          (fewer seconds airborne, less energy a mission) while the er
    ↪ ror stays in the middle of its band; past the wall the
          cruise is the planner's at once (fail up). The override neve
    ↪ r goes under the planner's cruise or over twice it,
          and never past the autopilot's speed limit.
```

```
Energy is a declared model (evidence class S), the same for both arms:
    ↪  each motor's mechanical power from the simulator's
own thrust and torque constants (torque = KM rpm^2, power = torque x a
    ↪ ngular speed), divided by a declared motor
efficiency, plus a declared avionics draw for every drone over the who
    ↪ le fleet window, flying or landed. The battery is

the Crazyflie's (250 mAh at 3.7 V); the autopilot's own reserve rule (
    ↪ 20% left at landing) decides a reserve breach.
Collisions are read from the simulator: any two drones closer than two
    ↪  collision radii. A cell where native itself
collides is void and says so; a collision with Omni-Compass on top is
    ↪ a judged row, any increase a LOSS (amendment 2,

from omni-v12's runs on). Every row is reported, LOSS included.

  python3 tools/run_swarm.py --cell tuning --out DIR        # the tuni

"""Omni-Compass on top of a database's operator-set buffer pool: sysbe
    ↪ nch on MySQL (docs/MYSQL_PREREGISTRATION.md).

MySQL 8.0 as Ubuntu ships it, with the one setting an operator sets on
    ↪ ce for InnoDB: the buffer pool size, which the server
resizes online in chunks of 128 MB. sysbench's published OLTP workload
    ↪ s ask for rows from a set of tables that widens and
narrows over the run (one notch = one more table of a million rows), s

    ↪ o the working set steps through the operator's pool
and past it. The operator's fixed pool is the native controller here.

  native  MySQL at the operator's pool (512 MB) for the whole run
  omni    the same MySQL, with the compass law (omnicompass/compass_la
    ↪ w.py) on one knob, the buffer pool size, through the

          server's own console (SET GLOBAL innodb_buffer_pool_size), i
    ↪ nside the cover [128 MB, 2,048 MB]: the compass reads the
          workload's own mean statement latency over the last second (
    ↪ performance_schema, sysbench's account only, its prepared
          statements counted; store fix of 25 October) on a band from
    ↪ 0 to the statement

          line and holds it at 40% of the line; slow statements with t
    ↪ he pool full push the pool up a chunk or more (slow
          statements with room to spare are not the pool's to mend), c
    ↪ alm with the pool's misses under one percent of its read request
    ↪ s gives a chunk back
          (amendment 2: the pool grows only while it is missing, one p
```

"""Omni-Compass on top of a database's operator-set cache size: YCSB o
    ↪ n MongoDB (docs/YCSB_PREREGISTRATION.md).

MongoDB as its publisher ships it, with the one setting an operator se
    ↪ ts once for its storage engine's cache: the WiredTiger
cache size. YCSB (Yahoo's Cloud Serving Benchmark, the published core
    ↪ workloads) asks for records drawn from a key space that
widens and narrows over the run, so the working set steps through the

    ↪ operator's cache and past it. The operator's fixed
cache is the native controller here.

  native  MongoDB at the operator's cache size (512 MB) for the whole
    ↪ run
  omni    the same MongoDB, with the compass law (omnicompass/compass_

    ↪ law.py) on one knob, the cache size, through the
          server's own console (setParameter wiredTigerEngineRuntimeCo
    ↪ nfig cache_size), inside the cover [256 MB, 2,048 MB]:
          the compass reads the server's own mean read latency over th
    ↪ e last second (serverStatus opLatencies) on a band from
          0 to the response line and holds it at 40% of the line; slow
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    ↪  reads with the cache full and missing push the cache up
          (slow reads with room to spare, or in a cache that holds its
    ↪  working set, are not the cache's to mend), calm gives
          memory back 64 MB a second while the cache's misses are unde
    ↪ r one percent of the pages requested from it (amendment
          1: it holds the working set; the first counted set read "not

    ↪ hing evicted", which a cold cache satisfies while it fills);
          at 95% of the line with the cache full a quarter of the cove
    ↪ r is added at once (fail up); the cache size is handed
          back to the operator's at the end and read back; a size foun
    ↪ d at a value Omni did not write stops it writing

Gauges from YCSB's own per-operation records (every operation's latenc
    ↪ y, raw), the server's own serverStatus (the cache
configured, the bytes in it, pages read into it) and the host's /proc/
    ↪ stat (CPU seconds, the compass's own cost included).
Memory held is the resource; no energy is claimed beyond the host's CP
    ↪ U seconds. Every row is reported, losses included.

  python3 tools/run_ycsb.py --setup                        # fetch and
    ↪  check YCSB, point the server at the operator's cache
  python3 tools/run_ycsb.py --workloads tuning --reps 3 --out DIR
  python3 tools/run_ycsb.py --report-only DIR              # re-read f
    ↪ inished <workload>.json files and write YCSB.md

```
    ↪ ever below native; the memory it takes is power given,
shown beside the misses it bought off; the tune-down (`dial save`) kee
    ↪ ps omni-v21's loop, where giving memory back is the aim.
Where the memory can bring the knob no GAIN, the knob stays native (th
    ↪ e engine's strictest form, the founder's words of 19
October): on a store that is not slow for want of memory, memory is no
    ↪ t spent.

Four pieces, each read from the store's and the host's own meters, not
    ↪ hing written for a workload:

  the working set's floor   the most memory the store held in the last
    ↪  HOLD_WINDOW_S, with the fullness margin, rounded up to a
                            notch, never under native nor over the cov
    ↪ er: a knob handed back below it evicts what the service
                            still asks for, and the next rise buys it
    ↪ back at the store's price (the sawtooth the Redis model
                            showed on a candidate without it)

  the cost of the misses    the store's own account: the share of the
    ↪ service's own time that its misses are, over
                            WORTH_WINDOW_S. MySQL: the performance sch
    ↪ ema's timer on the data files' reads against the
                            workload's statement timer; MongoDB: Wired
    ↪ Tiger's time reading pages from disk for the application's
                            threads against the server's own read late
    ↪ ncy; Redis: the application's own split of each request
                            into hits and misses. A slope of latency o
    ↪ n miss share was tried first and is not used: on the
                            archived runs it read 0.5 to 1.2 ms a unit
    ↪  of miss share inside the arms, while the controlled
                            comparison across pool sizes (a third of t
    ↪ he misses gone, the latency unmoved) read none; the
                            seconds' noise is shared by both, and the
    ↪ slope reads it as a price
  the gate                  memory is spent only where that share is M
    ↪ ISS_WORTH or more, the one key's own floor (a change of

APPENDIX

Appendix I. The License

The license under which this book and the software are made available, as it stands in the file `LICENSE` at the root of the repository.

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
Omni-Compass Evaluation License, version 1.0 (revised 11 October 2026)
SPDX-License-Identifier: LicenseRef-OmniCompass-Evaluation-1.0

Copyright (c) 2026 Dubra Software Inc. / The Omni-Compass LLC. All rig
    ↪ hts reserved.
All patents, copyrights and trademarks filed in the USA. www.omni-comp
    ↪ ass.com

THIS IS NOT AN OPEN-SOURCE LICENSE. The Software is proprietary. It is
    ↪  published so that it can be evaluated, reproduced
and audited, and for no other purpose. It is licensed, not sold. Evalu
    ↪ ation and simulation are free of charge; every

other use, and in particular every commercialization or monetization o
    ↪ f any kind, requires a signed, paid Omni-Compass
Enterprise License.

ACCEPTANCE. By downloading, copying, forking, installing, running, sca
    ↪ nning or otherwise using any part of the Software,

You accept this license. If You do not accept it, You may not use the
    ↪ Software. If You use the Software on behalf of an
organization, You represent that You have authority to bind it, and "Y
    ↪ ou" includes that organization and its
Affiliates.

1. DEFINITIONS

   1.1 "Licensor" means Dubra Software Inc. / The Omni-Compass LLC.
   1.2 "Software" means everything Licensor publishes or makes availab
    ↪ le under this license, in any form: the source
       code and any object code; the Omni-Compass engine, the compass

    ↪ law, the governors, controllers, brains, shields,
       plugs and wiring; the harnesses, tools, scripts, workflows, con
    ↪ figurations, presets, catalogs, organisms and realms;
       the documentation, the manual, the book, the specifications, th
    ↪ e preregistrations and the receipts; the benchmarks,
       data, tables, reports and Results published by Licensor; and ev
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
 ↪ ery update, version and copy of any of them.
1.3 "Mechanism" means the methods, processes, control laws, algorit
 ↪ hms, architectures and systems embodied in or
    described by the Software, including everything described in th
 ↪ e patent applications Licensor has filed.
1.4 "Evaluation" means internal use by You, free of charge, solely

 ↪ to test, study and assess the Software in
    contemplation of an Enterprise License: reading it; running its
 ↪  tests, verifiers, benchmarks and simulations; and
    running it in observe, watch, dry-run or shadow mode, or in a t
 ↪ est environment, on systems You own or control,
    where it writes to no system that serves production traffic, re

 ↪ al users, customers, patients or passengers, and to
    no power system, vehicle, machine or physical process outside a
 ↪  test bench.
1.5 "Simulation" means running the Software against modelled, recor
 ↪ ded or synthetic systems, including the organisms,
    realms, traces and simulators published with the Software.

1.6 "Production Use" means any use that is not Evaluation or Simula
 ↪ tion, including any use in which the Software, the
    Mechanism or any output of either controls, governs, tunes, siz
 ↪ es, schedules or otherwise influences a system that
    serves production workloads or real users, or any physical proc
 ↪ ess outside a test bench.

1.7 "Commercial Use" means any use for, or in connection with, comm
 ↪ ercial advantage, revenue, cost reduction in
    operations, or monetary or other compensation, including consul
 ↪ ting, integration, managed, outsourcing, training,
    benchmarking-for-hire and advisory services, and any use by or
 ↪ for a for-profit operation beyond Evaluation.

1.8 "Hosted Service" means making the Software, the Mechanism or an
 ↪ y of their functionality available to any third
    party over a network or as a service, including software-as-a-s
 ↪ ervice, platform-as-a-service, a managed or
    outsourced service, a cloud marketplace offering, or a feature
 ↪ of another product or service.
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
   1.9 "Derivative" means any modification, adaptation, translation, p
    ↪ ort, extension or re-implementation of the Software
       or of the Mechanism, and any work that incorporates, is based o
    ↪ n, or is built using the Software as a reference.
   1.10 "Results" means the measurements, tables, receipts, logs, repo
    ↪ rts and other outputs produced by running the

       Software.
   1.11 "Enterprise License" means a written agreement for the Softwar
    ↪ e signed by Licensor and a licensee, under which
       the licensee pays the fees it sets out; it may include order fo
    ↪ rms, riders and statements of work.
   1.12 "Marks" means the names "Omni-Compass" and "OmniCompass", the

    ↪ Omni-Compass compass rose with its ring of Greek
       letters, and every related name, logo and trade dress of Licens
    ↪ or.
   1.13 "Affiliate" means any entity that controls, is controlled by,
    ↪ or is under common control with You, where control
       means ownership of more than half of the voting interests or th

    ↪ e power to direct management.
   1.14 "You" means the individual or entity exercising rights under t
    ↪ his license, with its Affiliates where the
       Acceptance paragraph above includes them.

2. WHAT THIS LICENSE ALLOWS

   2.1 Copyright license. Subject to Your compliance with this license
    ↪ , Licensor grants You a personal, worldwide,
       royalty-free, non-exclusive, non-transferable, non-sublicensabl
    ↪ e and revocable license to download, copy, read,
       run and modify the Software solely for Evaluation and Simulatio

    ↪ n, and to reproduce and publish Results as section
       4 allows.
   2.2 Patent license. Subject to the same conditions, Licensor grants
    ↪  You a license of the same scope, under the patent
       rights Licensor holds or will hold in the filed applications an
    ↪ d any patent issuing from them, solely to the
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
      extent needed to carry out Evaluation and Simulation with the S
   ↪ oftware. No patent license is granted for any
      Production Use, Commercial Use or Hosted Service, for any Deriv
   ↪ ative used outside Evaluation or Simulation, or for
      any implementation of the Mechanism other than the Software its
   ↪ elf.

   2.3 Forks. You may keep a copy or a fork of the Software on a code-
   ↪ hosting service, publicly or privately, only for
      Evaluation and Simulation, with this license and every notice i
   ↪ ntact. A fork confers no right beyond this license.
   2.4 Reservation. Every right not expressly granted is reserved by L
   ↪ icensor. No right, title, license or interest is

      granted by implication, estoppel, exhaustion or otherwise.

3. WHAT THIS LICENSE DOES NOT ALLOW

   Unless an Enterprise License expressly permits it, You may not, and
   ↪  may not let or help anyone else:

   (a) make any Production Use or Commercial Use of the Software, the
   ↪ Mechanism or any Derivative;
   (b) commercialize or monetize the Software, the Mechanism, any Deri
   ↪ vative or any Result in any way, directly or
      indirectly, including by charging for access, services, support
   ↪ , results, savings or outcomes they produce;

   (c) offer the Software, the Mechanism or any Derivative as, or as p
   ↪ art of, a Hosted Service;
   (d) sell, resell, license, sublicense, lease, rent, lend, distribut
   ↪ e, publish as a package or binary, or otherwise
      transfer the Software or any Derivative, except forks under sec
   ↪ tion 2.3;

   (e) incorporate the Software, any part of it or any Derivative into
   ↪  any product, service, platform, appliance, image,
      firmware or offering;
   (f) use the Software, the Mechanism, the documentation or the Resul
   ↪ ts to design, build, train, tune, benchmark for
      sale, or improve any product or service that competes with Omni
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    ↪ -Compass, or to re-implement the Mechanism;
   (g) use the Software or the Results to train, fine-tune or evaluate
    ↪  any machine-learning model intended to reproduce,
       imitate or substitute for the Mechanism;
   (h) remove, alter or obscure any notice, the SPDX identifiers, the
    ↪ patent and trademark notices, this license, the

       NOTICE or DISCLOSURES.md, or circumvent, disable or work around
    ↪  any limit, switch or safeguard in the Software,
       including the kill switch and the hand-back to native settings;
   (i) connect the Software so that it writes to a safety-critical sys
    ↪ tem, as section 10 describes;
   (j) use the Marks, except to refer to Omni-Compass accurately as TR

    ↪ ADEMARKS.md allows; or
   (k) use the Software in violation of any law, or in breach of secti
    ↪ on 11.

4. REPRODUCING AND PUBLISHING RESULTS

   You may reproduce the benchmarks published with the Software and pu
    ↪ blish Your own Results, provided that You: (a)
   name the Software's engine version and the exact commit You ran; (b
    ↪ ) report every measured row, the unfavourable ones
   included, with the evidence class the Software assigns to it; (c) m
    ↪ ake Your complete raw files and configuration

   available to Licensor on request; (d) do not state or imply any end
    ↪ orsement, certification or affiliation by
   Licensor; and (e) carry the notice at the top of README.md. Publish
    ↪ ing Results is not Commercial Use so long as no
   compensation is received for it, and it grants no right beyond this
    ↪  license.

5. THE OMNI-COMPASS ENTERPRISE LICENSE

   5.1 Every Production Use, Commercial Use, Hosted Service, distribut
    ↪ ion, incorporation, OEM or embedded use, and every
       other commercialization or monetization of the Software, the Me
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    ↪ chanism or any Derivative requires an Enterprise
       License, signed before the use begins and paid as it provides.
    ↪ Moving from Evaluation to Production Use requires
       an Enterprise License before the first write to any production
    ↪ system.
   5.2 An Enterprise License sets its own scope, fees, term, support,

    ↪ warranties, indemnities and limits
       (ENTERPRISE_LICENSE.md summarizes the standard terms; the signe
    ↪ d agreement alone is binding). For its licensee and
       its scope, a signed Enterprise License governs where it differs
    ↪  from this license.
   5.3 Enterprise licensing: Dubra Software Inc. / The Omni-Compass LL

    ↪ C, main office infrastructure, toll-free direct 1-888-339-9551,
    ↪ system route asset 1-888-DEX-YLL-1, landline 321-746-4411 regist
    ↪ ered in Florida, www.omni-compass.com.

6. OWNERSHIP AND INTELLECTUAL PROPERTY

   6.1 Licensor and its licensors own the Software, the Mechanism, the
    ↪  Marks and all intellectual property rights in
       them, including in every Derivative to the extent it embodies t
    ↪ hem. Nothing in this license transfers ownership.
   6.2 All patents, copyrights and trademarks covering the Omni-Compas
    ↪ s engine, its mathematics and its software have

       been filed in the United States by Dubra Software Inc. / The Om
    ↪ ni-Compass LLC. No filing number is stated here, and no grant,
       registration or approval is claimed; the status of every filing
    ↪  is held by the office where it was filed. Every
       person who downloads, copies, forks, scans or runs the Software
    ↪  is on notice of these filings and of this

       license (PATENTS.md, TRADEMARKS.md).
   6.3 Any use outside this license, without an Enterprise License, is
    ↪  unlicensed and infringes Licensor's copyright and
       other rights, in addition to breaching this license.

7. PATENT AND RIGHTS DEFENSE
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
   If You or any of Your Affiliates bring or join any claim, countercl
    ↪ aim or proceeding alleging that the Software or
   the Mechanism infringes, misappropriates or violates any patent, co
    ↪ pyright or other intellectual property right, or
   challenge the validity or enforceability of any of Licensor's right

    ↪ s in them, every license granted to You under this
   license ends automatically on the date the claim or challenge is fi
    ↪ led.

8. FEEDBACK AND CONTRIBUTIONS

   8.1 If You give Licensor comments, suggestions, ideas, reports or o
    ↪ ther feedback about the Software, You grant
       Licensor a perpetual, irrevocable, worldwide, royalty-free righ
    ↪ t to use, disclose and exploit it for any purpose,
       without obligation of any kind.
   8.2 Contributions are accepted only under the contributor license a

    ↪ greement (.github/CLA.md).

9. CHANGES

   Licensor reserves the right to change the Software, its documentati
    ↪ on, its results and these terms at any time,

   without notice. A changed version of these terms applies to every c
    ↪ opy of the Software obtained, and to every use
   made, after it is published in the Software's repository; continued
    ↪  use after publication is acceptance of the
   changed terms. Licensor may discontinue the Software, or this licen
    ↪ se for future copies, at any time.

10. SAFETY

   The Software is not designed, tested or certified for safety-critic
    ↪ al use. Under this license it may not write to
   any system whose failure could cause death, injury, environmental d
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    ↪ amage or significant property damage, including
   vehicles and aircraft, medical devices, power-grid protection and d
    ↪ ispatch, industrial safety systems and life-safety
   systems; such systems may be studied only in Simulation. Any live c
    ↪ onnection to a physical system requires an
   Enterprise License, a written safety case accepted by the system's

    ↪ owner, and every review that system's regulator or
   owner requires. The machines' own controls and protections stay in
    ↪ place; the kill switch must remain operable at all
   times.

11. EXPORT CONTROL, SANCTIONS AND LAWFUL USE

   You will comply with every export-control, sanctions, anti-corrupti
    ↪ on and other law that applies to the Software and
   to Your use of it, including the U.S. Export Administration Regulat
    ↪ ions and the sanctions administered by the U.S.
   Treasury's Office of Foreign Assets Control. You represent that You

    ↪  are not located in, organized under the laws of,
   or ordinarily resident in a country or region subject to comprehens
    ↪ ive U.S. sanctions, and that You are not on, or
   owned or controlled by a party on, any U.S. restricted-party list.
    ↪ You will not use the Software for any end use
   prohibited by those laws, including the design, development or prod

    ↪ uction of weapons of mass destruction.

12. DATA AND PRIVACY

   The Software contains no telemetry. It sends nothing to Licensor an
    ↪ d makes no network connection of its own except to

   the systems You point it at. Your data and Your Results stay on You
    ↪ r systems and are Yours, subject to section 4. If
   You send Licensor any material (for example in an issue or an e-mai
    ↪ l), You represent that You may lawfully do so and
   that it contains no personal data or confidential information of an
    ↪ y third party.
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
13. THIRD-PARTY COMPONENTS

   Files that carry a different license notice (for example tests/thir
    ↪ d_party/) and third-party data sets (for example
   the PlanetLab traces under fleet/traces/ and k8s_controlplane/trace

    ↪ s/) remain under their own terms
   (THIRD_PARTY_NOTICES.md). Third-party software the Software runs on
    ↪  or connects to (Kubernetes, KEDA, Karpenter,
   NVIDIA drivers, databases and others) is licensed by its owners und
    ↪ er their own terms.

14. TERM AND TERMINATION

   14.1 This license lasts until it ends under this section or section
    ↪  7.
   14.2 It ends automatically, without notice, if You breach it. If Yo
    ↪ ur breach is Your first, was inadvertent, and is

       not a breach of sections 3(a) to 3(g) or section 10, Your lice
    ↪ nse is reinstated if You cure the breach within
       thirty days after You learn of it or after Licensor notifies Y
    ↪ ou, whichever comes first.
   14.3 Licensor may end this license for any person at any time by wr
    ↪ itten notice, and for all persons for future

       copies under section 9.
   14.4 When this license ends, You must stop all use of the Software,
    ↪  delete or destroy every copy and Derivative in Your
       possession or control, and, on request, certify in writing tha
    ↪ t You have done so.
   14.5 Sections 1, 3, 4(b) to 4(e), 6, 7, 8, 11, 12, 15 to 18 and 19

    ↪ survive the end of this license.

15. NO WARRANTY

   TO THE FULLEST EXTENT PERMITTED BY LAW, THE SOFTWARE, THE MECHANISM
    ↪  AND THE RESULTS ARE PROVIDED "AS IS" AND "AS
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
   AVAILABLE", WITH ALL FAULTS AND WITHOUT WARRANTY OR CONDITION OF AN
    ↪ Y KIND, EXPRESS, IMPLIED OR STATUTORY, INCLUDING ANY
   WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITL
    ↪ E, NON-INFRINGEMENT, ACCURACY, QUIET ENJOYMENT, OR
   THAT THE SOFTWARE WILL BE ERROR-FREE OR UNINTERRUPTED. NO RESULT IS
    ↪  A PROMISE OF ANY OUTCOME ON ANY OTHER SYSTEM;

   MODELLED RESULTS (EVIDENCE CLASS S) ARE STATEMENTS ABOUT THE MODEL,
    ↪  NOT MEASUREMENTS (DISCLOSURES.md). YOU USE THE
   SOFTWARE AT YOUR OWN RISK AND ARE RESPONSIBLE FOR ITS USE ON YOUR S
    ↪ YSTEMS.

16. LIMITATION OF LIABILITY

   TO THE FULLEST EXTENT PERMITTED BY LAW, LICENSOR, ITS MEMBERS, MANA
    ↪ GERS, EMPLOYEES, CONTRACTORS AND LICENSORS SHALL NOT
   BE LIABLE FOR ANY INDIRECT, INCIDENTAL, SPECIAL, CONSEQUENTIAL, EXE
    ↪ MPLARY OR PUNITIVE DAMAGES, OR FOR ANY LOSS OF
   PROFITS, REVENUE, SAVINGS, DATA, USE OR GOODWILL, OR ANY COST OF SU

    ↪ BSTITUTE GOODS OR SERVICES, ARISING OUT OF OR
   RELATING TO THE SOFTWARE, THE MECHANISM, THE RESULTS OR THIS LICENS
    ↪ E, UNDER ANY THEORY OF LIABILITY, EVEN IF ADVISED OF
   THEIR POSSIBILITY. LICENSOR'S TOTAL LIABILITY FOR ALL CLAIMS SHALL
    ↪ NOT EXCEED ONE HUNDRED U.S. DOLLARS (USD 100). THESE
   LIMITS APPLY EVEN IF A REMEDY FAILS OF ITS ESSENTIAL PURPOSE.

17. INDEMNITY

   You will defend, indemnify and hold harmless Licensor and its membe
    ↪ rs, managers, employees and contractors from and
   against every claim, loss, liability, damage, cost and expense (inc

    ↪ luding reasonable attorneys' fees) arising out of
   or relating to (a) Your use of the Software outside this license, (
    ↪ b) any Production Use, Commercial Use or Hosted
   Service without an Enterprise License, (c) Your Derivatives, (d) Yo
    ↪ ur Results as You publish them, or (e) Your
   violation of any law or third-party right.
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
18. U.S. GOVERNMENT END USERS

   The Software is "commercial computer software" and "commercial comp
    ↪ uter software documentation" as those terms are
   used in 48 C.F.R. 2.101, 12.212 and 227.7202. A U.S. Government end
    ↪  user acquires only the rights set out in this
   license, consistent with 48 C.F.R. 12.212 and 227.7202-1 through 22
    ↪ 7.7202-4.

19. GENERAL

   19.1 Governing law. This license is governed by the laws of the Sta
    ↪ te of Delaware and the federal laws of the United
        States, without regard to conflict-of-laws rules. The United N
    ↪ ations Convention on Contracts for the
        International Sale of Goods does not apply.
   19.2 Venue. The state courts of the State of Delaware and the Unite
    ↪ d States District Court for the District of
        Delaware have exclusive jurisdiction over any dispute arising
    ↪ out of or relating to this license, and You consent
        to their personal jurisdiction. Licensor may seek
        injunctive or other equitable relief in any court of competent
    ↪  jurisdiction, without posting a bond, to protect
        its intellectual property or confidential information; a breac
    ↪ h of sections 3 or 10 would cause Licensor
        irreparable harm.
   19.3 Enforcement costs. In any action to enforce this license, the
    ↪ prevailing party may recover its reasonable
        attorneys' fees and costs.
   19.4 Assignment. You may not assign or transfer this license or any
    ↪  right under it, by operation of law or otherwise;
        any attempt is void. Licensor may assign this license freely.
   19.5 Notices. Notices to Licensor go to Dubra Software Inc. / The O
    ↪ mni-Compass LLC by telephone at its main office infrastructure (
    ↪ toll-free direct 1-888-339-9551; system route asset 1-888-DEX-YL
```

© 2026 Dubra Software Inc. / The Omni-Compass LLC. All rights reserved. Evaluation and Simulation use only.
All patents, copyrights and trademarks filed in the USA.

```
    ↪ L-1, landline 321-746-4411 registered in Florida) or through www
    ↪ .omni-compass.com. Licensor may give notice to
        You through the Software's repository or at any address You ha
    ↪ ve given it.
   19.6 Severability and waiver. If any provision is held unenforceabl
    ↪ e, it is enforced to the maximum extent permitted and

        the rest of this license remains in effect. No failure or dela
    ↪ y in enforcing any provision is a waiver of it.
   19.7 Entire license. This license, with the NOTICE and DISCLOSURES.
    ↪ md, is the entire agreement between You and
        Licensor about its subject; for a licensee and its scope, a si
    ↪ gned Enterprise License governs where it differs.

   19.8 Interpretation. "Including" means "including without limitatio
    ↪ n". Headings are for convenience only. The
        English text of this license controls over any translation.
   19.9 Copies. Every copy, fork, export, report, archive or printout
    ↪ of any part of the Software must carry this
        LICENSE, the NOTICE and DISCLOSURES.md unchanged.

All rights reserved. Revision history: version 1.0 (evaluation and sim
    ↪ ulation only; first published 2026); revised
10 October 2026 (the notice in one wording everywhere); revised 11 Oct
    ↪ ober 2026 (definitions, patent license for
evaluation, hosted-service and machine-learning restrictions, results

    ↪ publication, patent and rights defense, safety,
export control, data, U.S. Government end users, term, cure, indemnity
    ↪ , Delaware governing law and venue).

Enterprise licensing: Dubra Software Inc. / The Omni-Compass LLC, main
    ↪  office infrastructure, toll-free direct 1-888-339-9551, system

    ↪ route asset 1-888-DEX-YLL-1, landline 321-746-4411 registered in
    ↪  Florida, www.omni-compass.com

APPENDIX

Appendix J. Reproducing Everything, From a Clean Machine

A referee with a laptop and a GitHub account can rebuild every table in this manual and rerun every benchmark. The steps, in order, with what each costs:

1. **Get the code and prove it is the code.** `git clone` the repository, `pip install -r requirements.txt` under Python 3.12 (the version GitHub runs), then `python3 verify.py`: it checks every sealed file's fingerprint, runs every test in `tests/`, including the rules of every three-run table on fixed cases, and ends `VERIFICATION: PASS`. About ten minutes on a laptop. `python3 tools/omni_version.py` then says which frozen engine the checkout carries.
2. **Rebuild any table from its raw files.** Every three-run table names its three run ids; their files are in `results/live/raw/run-<id>/` once the branch `raw` is opened there (`bash scripts/raw_archive.sh open /run-<A>/ /run-<B>/ /run-<C>/`). `python3 tools/confirm_abc.py "<title>" results/live/raw/run-<A> results/live/raw/run-<B> results/live/raw/run-<C> --out /tmp/check.md` rebuilds a Kubernetes or Azure table; `tools/pgbench_abc.py`, `kafka_abc.py`, `redis_abc.py`, `ycsb_abc.py`, `swarm_abc.py`, `mujoco_abc.py`, `pandapower_abc.py` and `citylearn_abc.py` the others, with the same arguments. Compare the result with the committed table: they are the same bytes below the legal notice. A few seconds each.
3. **Rebuild the index and the dossier.** `python3 tools/omni_index.py` reads every `V1_*.json` and `V3_*.json` table and writes `results/OMNI_INDEX.md`; `python3 tools/dossier.py` writes `docs/DOSSIER.md` and its charts. Seconds.
4. **Rerun a benchmark.** Every benchmark is a GitHub Actions workflow with its inputs documented at its head (`.github/workflows/`): `benchmark-reps` for the Kubernetes tests (`duration_s`, `arms`, `loadgen`, `load_steps`, `faults`, `workload`), `pgbench`, `kafka`, `redis`, `ycsb`, `swarm`, `robustness`, `citylearn`, `pandapower`, `mujoco`, `six`, `six-kube`. Dispatch it three times for A, B and C; each run archives its files when its id is added to `.github/archive_request.txt`. The Kubernetes tests run on GitHub's free runners in about an hour each; the database, broker, cache and swarm runs in about half an hour; the organisms at 1,000 copies need a rented machine (`aks-metered`

All patents, copyrights and trademarks filed in the USA.

and `big-organism-detached` need an Azure subscription and its credentials in the repository's secrets).

5. **Run it on your own system.** Chapter 57 is the method; `scripts/kind_paired.sh` and `tools/live_reps.py` are the tools; the preregistrations are the templates for writing your own rules down before you run.
6. **Check a result against its preregistration.** Each `docs/*_PREREGISTRATION.md` was committed before its first counted run; `git log` on the file shows when, and every amendment carries its own date and reason in the text.

Nothing in this chain requires a credential, a licence key or a word from us; the evaluation licence covers all of it.

BACK MATTER

Index

Every term of the glossary where this book defines or discusses it, every muscle family where it is named, every file of the repository and every command-line setting this book names, with the pages they stand on. A plain mention of a common word is not an entry: the index points to where a thing is explained. A term whose pages would run past its line keeps the pages that fit, where it is defined and first used; after those it is throughout the book.
